## Foreword

### *A Brief History of Classifying Birds*

*"Everything that proceeds from the mind or the hands of man, is, in the universal sense of the term, artificial; for what is produced by the exertion of the human mental faculties, or the human corporeal organization, cannot be natural, cannot be, ipso facto, what exists in nature. But when nature is observed by man, and when man expresses in language or by visible signs, his conception of what he has thus observed in nature, the logical or predicative system, or assemblage of observed truths, so produced, is in the language of science, the natural system."*

William Swainson (1831)

The quest for a natural system to classify birds absorbed the interests of many writers over centuries before Swainson made this observation in a reply to criticisms of the Circular or Quinary System, a method of grouping five taxa at each level (order, family, genus, species) into circles. To show relationships, the larger or smaller circles touch or overlap with each other in various ways (O'Hara 1988). Swainson became a fanatical adherent of the scheme and promoted or defended it at every opportunity, and he was convinced that the long-sought goal of finding a "natural system" of classification of living things finally had been attained. Although applying it broadly in classifications, his main interest was ornithology and the reply in question was part of a review of a book on British birds whose editor/author had strong views on classifications, too (Rennie 1831; Swainson 1831). Swainson did not initiate the scheme but he seized its perceived potential so firmly that he soon fell out with its original proponent, an entomologist by the name of W. S. MacLeay, as well as with fellow supporters in ornithology. The year 1831 was in the middle of a period of active interest in the classification of birds, and philosophical writings on natural history were merging with anatomical and other investigations as never before (Barber 1980; Ritvo 1997). Within a few years the fallacies of Swainson's much-loved system had become apparent, forcing him out of the mainstream of ornithology. Nevertheless, variations lingered in Europe, where they competed with other schemes in attempts to resolve the same problem: how to classify birds.

To illustrate the historical progress of the classification of birds the Order Passeriformes is often highlighted. Recent studies have been very revealing in a group that has both perplexed and confused many earlier attempts to unravel their relationships. Collectively known as passerines (the song birds, or perching birds), they represent the most species-rich order of birds, containing nearly 60% of all bird species. They are conventionally divided into two main groups, the Suboscines and the Oscines, and their coverage in HBW begins with this volume. An important focus here is on the higher classification of birds, above the level of genus. The historical development of species concepts is another story (see Haffer 1997), although the two strands are obviously interconnected. The study of species underpins everything, but their grouping into higher categories – families, superfamilies, suborders, etc. – is problematical. The boundaries of bird groups were blurred or confused in the earliest works dating back to antiquity. By the late seventeenth century a workable classification of birds began to take shape, but the patterns we are familiar with today began to emerge only in the eighteenth century. However, these were also periods of increased activity and there was much competition and rivalry amongst the proponents of different classification methods and philosophies, a situation that would persist in one form or another for a good long time, as Swainson found in the 1830s.

After a brief account of the early history of birds and their classification, I have divided the remainder of this survey into three main sections. These represent three extended periods of activity dedicated towards working out the higher classification of birds (beta taxonomy, or macrosystematics: Storer 1971; Mayr & Ashlock 1991; Bock 1992). The first two ended in brief lulls when the goal of an acceptable classification was thought to have been achieved, before renewed investigations and reassessments, particularly using new techniques, started the process off all over again. I have called them “waves”, and today we are in the middle of the third wave. Although the periods defined for each wave may seem to be somewhat arbitrary, they are clearly marked by significant and influential publications on bird classification. The lulls between waves do not mean that nothing happened on the study of classification, but merely a temporary shift of focus when the goal of a working classification seemed to be a lesser priority. Of course, such complacency never lasted for long.

### *The beginnings of classifying birds: the search for a natural system*

Birds feature in the earliest records of human cultures. Modern species can be identified from prehistoric cave paintings; also on frescos, pottery, and the like, with some familiar images dating from Ancient Egypt (Houlihan 1996). In one way or another, the earliest cultures also classified the natural world around them. In surviving cultures that still follow traditional lifestyles, the results of anthropological research support the ancient evidence. For example, in New Guinea, classificatory systems matching the details obtained from modern taxonomic studies reveal the extent of the intimate knowledge of the local bird life within individual communities. Diamond (1966) examined results obtained from one village and found that of 120 bird species identified in the area, 110 had local names. While this meant that a few similar species shared the same name, others which can be difficult to identify in the field, such as scrubwrens (*Sericornis* spp.), were identified separately. On the other hand, species with distinctive males and females had separate names. Although many names were based on colour, calls or certain habits, others were said to have no meaning.

From what we know of the written records that have come down to us from classical antiquity, the various schools of natural philosophy shared a desire to understand and interpret the world around them. The earliest known works come from Ancient Greece, beginning with Anaximander (611-546 BC) of the school of Ionian philosophers; he described the results of his scientific researches in an influential poem, *περι φύσεως* (*On Nature*). Anaximander was a student of Thales of Miletus (c. 625-547 BC), the earliest philosopher whose writings are known today. However, none of what survives of Thales's work demonstrates the interest in biology shown by his pupil. Anaximander's students and disciples, and later others, continued to research and expand their views on the natural world.

The earliest known comprehensive study of birds dates from the writings of Aristotle (384-322 BC). He was a disciple of Plato (429-347 BC), who in turn had been a disciple of Socrates (c. 469-399 BC), demonstrating the succession of important philosophers who maintained and developed the ancient traditions, while also taking them in new directions. Tutor to Alexander the Great (356-323 BC), Aristotle spent several years travelling and living in various places before he settled in Athens. These travels provided him with opportunities to make observations that later found their way into his writings. In his *περι τῶν ζῴων ἱστορίαι* (*On the History of Animals*), he presented the results of his attempts to study all animal life known to him, supplying many details, notably about their external appearance, internal structure and habits. He also attempted the first classification of birds. He used two main systematic categories, the *genos*, a large group, and the *eidos*, the individual animal forms, roughly equivalent to the modern terms of order and species. The *genos* Ornithes was divided into five smaller groups: 1. Gamsonyches (birds of prey); 2. Steganopodes (swimming birds); 3. Peristeroides (pigeons and doves); 4. Apodes (swifts, swallows and martins); 5. all others not included in the four divisions. With the exception of the swallows and martins, all passerines were lumped together, along with forms such as woodpeckers. In spite of his detailed work, many of the 170 kinds of bird he listed remain unidentifiable.

Although Aristotle's works greatly influenced his successors and followers, later Greek philosophers moved away from studying nature in such detail. Eventually Aristotle's works were virtually forgotten and a focus on developing a workable classification system moved to the world of Ancient Rome where summarizing knowledge in an encyclopaedic form was well established. Gaius Plinius Segundus (AD 23-79), better known as Pliny the Elder, followed this trend and amassed everything he could into a series of 37 “books” collectively entitled *Historia Naturalis*. Birds were covered in the

tenth book, where he placed great importance on the structure of the feet as the basis of his arrangement, but his texts were a disorderly collection of information, with details from folklore, magic and superstition mingled amongst general information, including personal observations. Recipes and medical cures also featured in early works covering birds and, along with everything else, such details were repeated for centuries.

This compendium, generally unreliable from a zoological perspective, was very influential on the writings of the later Roman and early Christian times. In fact, for almost 1500 years, Pliny's encyclopaedia, in particular, was highly regarded and it was copied, extracted and adapted over the centuries. However, in other areas Pliny's work was only one of various sources used, and only when they could be reconciled with Christian morality. Around the year 370 Christian teachers, most probably based in Alexandria, sought religious significance in bird and animal stories to present allegories supporting the doctrines of the Scriptures. The resulting compilation from Greek, Egyptian and Jewish sources, marrying natural history with moral theology, was known as the *Physiologus*, and it was widely translated. In the meantime, other allegorical works appeared, which were collectively known as Bestiaries. With some updating from time to time, these were the sources for information on animals through the period known in Europe as the Dark Ages.

The philosophical differences between religious doctrine and scientific thought continued in the Eastern Roman Empire, where the Emperor Justinian I (483-565) decided in 529 to close all Greek schools in order to suppress competition with those of the Christian church. This movement against secular learning spread. In Spain, Isidore (570-636), Bishop of Seville preserved what he could from the censorship of ideas contrary to Christian teaching in an encyclopaedic work where classical learning could serve the needs of the students of the church. The result was *Etymologies sive origines*, or simply the *Etymologia*. Birds were treated in Chapter 7 of his Book XII on animals. For birds he established the term "aves" because birds travelled by pathless ways or roads (*viae*). Misinformation dominates the chapter, showing the deterioration of knowledge of the natural world after several centuries.

Aristotle had not been completely forgotten, and Boetius (480-524), a keen collector of Greek documents, was the first to translate some of his writings into Latin, but this had little influence. Scholars in Syria, beginning with Porphyry (233-c. 304), had also extensively translated and commented on his works, and by the period 800-1100, most of Aristotle's works had been translated into Arabic. The Arab scholars were mainly based in Baghdad, where Greek science and philosophy were widely studied. The two best known translators around this time, who also put their own interpretations on his works, were Avicenna (980-1037) and, particularly, Averroes (1126-1198), who lived in Spain, then occupied by Moslems, after their invasion in the eighth century.

The Aristotle that became influential in European universities of the time owed much to the philosophical views of Averroes. Around 1230 the polyglot scholar Michael Scot (1175-1232) travelled to Spain, where he could read Aristotle in the original Arabic of both Averroes and Avicenna. He subsequently translated Averroes's work into Latin. Frederick II of Hohenstaufen (1194-1250) was keenly interested in birds and invited Scot to his court to share his knowledge of Aristotle. Frederick found Aristotle's *Historia Animalium* to be inadequate when compared to his own knowledge of birds, which he put in a book, *De arte venandi cum avibus*. It was much more than just a book on hunting with birds, as it also included a classification of birds based on ecology and diet. This enlightened work was well ahead of its time. However, it was ignored by the ecclesiastical naturalists of the period because of Frederick's excommunication by the Pope. Although a version was eventually printed as late as in 1596, its value to ornithology only began to be appreciated in 1788. A complete version, based on all available sources, finally appeared only 60 years ago (Wood & Fyfe 1943).

The re-emergence of Aristotle continued when two Dominicans rediscovered his work and wrote commentaries. Albert von Bollstädt (1193-1280), better known as Albertus Magnus, a teacher of theology, used Scot's translation and later wrote commentaries on it in *De Animalibus*, between 1260 and 1270 (first printed in 1478). His disciple, Thomas de Cantimpré (c. 1210-1293) had already done this in *De Natura Rerum*, between 1233 and 1248. A century later, *De Natura Rerum* gained wider circulation when selected parts of it were translated into German by Conrad von Meigenberg (c. 1309-1374) as *Das Buch der Natur*, first published, with wood cuts, in 1475. These works originated as attempts to separate philosophy and theology in understanding the natural world, but they still carried much misinformation. Times were slowly changing, however, and even Albertus and later scholars of the period, notably William of Occam (1270-1347), were able to reconcile natural and church philosophies so that Aristotle could stand as a representation of the views of the church.

The spread of what became known as the Renaissance movement began in the fifteenth century, through the effects of several major events. Those of significance to the classification of birds included: the exile of Greek scholars in Europe, from as early as about 1430 but particularly after the fall of Constantinople in 1453; the invention of printing; and, later, the discovery of the New World. One Greek scholar, Theodorus Gaza, brought Aristotle's works with him and as early as 1476 published in Latin the *Libri de Animalibus*, with a Greek edition appearing in 1495. Printing made books widely available, with the ancient texts and knowledge reaching a much broader readership. The beginnings of extensive global exploration provided new insights for understanding the diversity of the natural world.

It was at this point in history that the man later called the Father of Ornithology appeared. William Turner (c. 1500-1568) was a widely travelled naturalist both in his native England and in Europe, often not by choice but because of religious differences. He turned his interest in philology to classical natural history and sought to make an accurate interpretation of the names in the works of Aristotle and Pliny, publishing his results in his little book *Avium præcipuarum, quarum apud Plinium et Aristotelem mentio est, brevis et succincta historia* (1544). He also included many of his own extensive observations, making it the first bird book treated in a scientific spirit. In his lifetime, he published 31 books on plants and animals, all praised for their accuracy, and indeed he is also known as the Father of English Botany (Mullens 1908a). Turner concluded his studies by hoping that a new Aristotle would emerge to revise and update what was known about natural history. He did not have long to wait.

Conrad Gesner (1516-1565), based in Switzerland, was a great assembler and organizer of information. He was assisted in his work by several correspondents, including Turner, whose work he greatly admired. Birds were covered in the third volume of his *Historia Animalium* (1555), popularized by reprintings, in Germany in particular, for over a century. In this work he discussed and illustrated 217 different birds, including those of mythology, even though he did not believe they existed, but because he thought it would be of interest to the public. Gesner's work has been credited as representing the starting point of modern zoology. His earlier bibliographical studies have given him the name of the Father of Bibliography, and he also wrote an account of 130 known languages, with the Lord's Prayer given in 22 of them. He was also perhaps the first person to collect natural history objects and house them in a museum. As classification was poorly understood, he decided to present his encyclopaedic coverage of birds alphabetically. He died when plague ravaged his home city of Zurich.

Pierre Belon (1517-1564) travelled widely in Greece, Asia Minor, Egypt and Arabia, and wrote a popular account of his travels, including natural history (1553). He lived in various parts of Europe, as he was dependent on patronage. All these travels allowed him to embellish his reworking of the old authors in *L'histoire de la nature des oyseaux, avec leurs descriptions, et naïfs portraits, retirez du naturel* (1555). Although his work was generally ignored in his day due to the dominance of Gesner's publications - indeed he had been accused of plagiarism, even though his book appeared in the same year - it was well regarded by later writers. His classification was derived from Aristotle and Pliny. Like them, he separated birds on ecological and morphological principles into raptors, waterfowl with webfeet, fissiped marsh birds (including kingfishers and bee-eaters), terrestrial birds, large arboreal birds and small arboreal birds (including swallows). His book was also important for his attempts to understand anatomy, including a comparison of a human and a bird skeleton. In addition to his work on birds, Belon wrote on fish, and he was a keen botanist, with an interest in establishing exotic plant species in France, to which end he helped establish two botanical gardens. He was working on a book on plants when he was murdered one night while walking to his home in Paris.

Ulisse Aldrovandi (1522-1605) had contributed to Gesner's work but wanted to outdo him, and produced his encyclopaedic *Ornithologia* (1599-1603) in three volumes. In his youth he had been imprisoned as a heretic, as indeed for various reasons had Gesner, Belon and Coiter; in later life Aldrovandi taught botany. His first book was a treatise on drugs, which was to be of great use to later works on pharmacy, but ornithology was his main interest. The compilation, begun in the 1560s, was the most comprehensive of its kind up to that time. He criticized Gesner for using an alphabetical arrangement, and proceeded to follow a classification based on Aristotle. Birds were grouped by having a hard and powerful beak (raptors, parrots, ravens, woodpeckers, treecreepers, bee-eaters and crossbills); those that bathe only in dust or in dust and water (pigeons and buntings); songbirds (finches, larks and canaries); waterfowl; and shorebirds. As he put everything he could find into his work, including plagiarizing Gesner and Belon, its real value was sometimes considered to belong in the earlier works of those authors. He was also criticized for including few of his own

observations. However his work was judged, it was popular in its day and was continued for other animal groups after his death in his native Bologna, Italy, by several of his faithful students.

Volcher Coiter (1534-1576), born in the Netherlands but spending his working life in Italy and Germany, was the first person to base a classification of birds on structure instead of function. He devised a natural system following the guidelines of Aristotle and Pliny, based on morphology, in *De avium sceletis et præcipuis musculis* (1575). The section of this work entitled *De differentiis avium* contained the first diagram showing the relationships of birds. It also summarized his knowledge of the anatomy of birds in an interpretive way, resembling a key, or perhaps something approaching a cladogram (see Allen 1951a, 1951b). Although like Pliny he used form (i.e. morphology) with divisions based on the characters of the feet, his observations in the text demonstrate their relationships to function. His subdivisions followed the shape of the claw and the placement of the toes. No matter how it is viewed, his tabulation represents the beginnings of an attempt to derive a natural classification of birds based on morphology. In this way he anticipated the ideal “natural system” envisaged nearly 200 years later by Linnaeus – who had been influenced by the better-known attempt at a morphological classification a century later by Willughby and Ray.

Caspar Schwenckfeld (1563-1609), in Germany, was a follower of Aristotle and the works of Gesner and Aldrovandi, and made useful observations on the biology of birds. He is the author of the first regional bird list, in *Aviarium Silesiæ*, the fourth volume of his *Theriotropeum Silesiæ* (1603). He provided useful details of about 150 species found in his district, making a valuable early contribution to ornithology. He tried to classify birds according to their habitat, mobility, foot structure, food and colour, but finding these criteria unsatisfactory, he followed Gesner’s alphabetical arrangement. His inclusion of unreliable material from Gesner and Aldrovandi with his original observations represented a trend continued by some later writers.

John Jonston (or Johnstone), also Johannes Johnstonus (1603-1675), a Pole of Scottish descent, produced a compilation on birds from Aldrovandi and other earlier writers, but with nothing original, in his *Historiæ naturalis de avibus* (1650). Its value was in its illustrations, mostly reworking those of Gesner and Aldrovandi but also adding some new ones. It became popular and was widely distributed, translated, printed and used for over a century, last appearing in 1773. Arguably one of the least reliable or original books of the first flowering of modern ornithology became the most popular.

Christopher Merrett (1614-1695) provided the first printed list of British birds, *Aves Britannicæ*, in his *Pinax rerum naturalium Britannicarum* (1666, reprinted in 1667 because most copies were destroyed in the Great Fire of London). This was later considered by some to be a poor work by an author with little field experience. In classifying the birds, he mostly based his identifications on Aldrovandi and Jonston. Mullens (1908c) reviewed the list of 165 birds, demonstrating Merrett’s attempt to link his identifications with earlier works rather than using his own observations. Even at this late date the bat was still listed amongst birds! Around this time and later in Britain a number of local and county natural histories also appeared. Although such compilations had an earlier history dating back in printed form to at least 1486, their coverage of birds was incidental before Merrett compiled his list (Mullens 1908d). The only one that sought to provide some detail was that of Richard Carew (1555-1620) in his *The Survey of Cornwall* of 1602 (Mullens 1908b).

Walter Charleton (1619-1707), in his *Onomasticon zoicon* (1668, revised 1671), sought to provide a systematic classification of all birds. For familiar birds, he based it on Aldrovandi, with two main divisions, of waterbirds and landbirds. Waterbirds were further divided into palmipeds, fissipeds (fish-eaters and insect-eaters) and plant-eaters. Landbirds were further divided into meat-eaters (including bats!), seed-eaters (dust-bathing, dust- and water-bathing, and singing), berry-eaters, and insect-eaters (non-singing and singing). Passerines, like other groups, are scattered amongst these divisions, though mostly in the landbirds. When Charleton had to consider unfamiliar, exotic birds he put them in an appendix under either “Terrestres” or “Aquaticæ”. This was the last serious attempt to classify birds following Aristotelian principles. A new system was needed and it was soon to appear.

Francis Willughby (1635-1672) and John Ray (1627-1705), both English clergymen, met at Cambridge, where they developed a plan to record and describe all animals and plants according to their own natural philosophy of the world. Willughby worked most intensively on birds and insects, as well as other animals, and Ray principally on plants. They travelled widely together in Britain and Europe, collecting and recording all they could find. Willughby’s early death from pleurisy left his works unfinished, but he had made financial arrangements for Ray in his will, allowing Ray to edit and publish them (Raven 1942). The Latin *Ornithologiae* appeared in 1676,

followed by a revised edition in English, *The Ornithology of Francis Willughby*, in 1678. Although the amount of Ray's contribution to this work has been disputed, the final results obviously benefited from their close collaboration (Mullens 1909b). However the issue is interpreted, this important book founded the beginnings of scientific ornithology. It not only summarized material from older works, with an attempt to separate fact from fiction, but also included much new information; although the main focus was on descriptions of plumage and structure, some details of habits were added. To present this summary of ornithology, a strictly morphological classification was devised, based on beak form, foot structure, and body size. The triumph of form over function, already seen in the then little known work of Coiter, finally replaced the confusion of earlier attempts at creating a natural system of birds. The groupings of species began to resemble bird families recognized today. For example, amongst the passerines, finches, thrushes and crows were placed together.

Ray prepared a new summary of birds in the 1690s but it was still unpublished at the time of his death. As before, new information from the results of recent voyages and travels was added. Two notable collections used were those of Sir Hans Sloane (1660-1753) from Jamaica (1687-1689) and of Paul Hermann (1640-1695) from India and Ceylon (1672-1680). After Ray's death, the manuscript was revised by his friend William Derham (1657-1735), who expanded Ray's coverage of exotic birds by appending a manuscript on the birds of Madras, *Avium Maderaspatanarum*, the first regional list of Indian birds, which had been passed on to him by James Petiver (1663-1718). At the time, Petiver maintained one of the earliest natural history collections in England and corresponded with potential collectors for both illustrations and specimens of plants and animals. One was Georg Joseph Camel (1661-1706), a Jesuit based in Manila, whose interest in birds resulted in his *Observations de Avibus Philippensibus* (1703), the earliest regional paper on Asian birds. The Madras list, from an Edward Buckley, was also incorporated by Derham into Ray's glossary of foreign bird names and is notable for passerines as the source of the name "pitta", a local name for "bird", but subsequently associated with the members of the family Pittidae. This revised summary of *The Ornithology* appeared in the *Synopsis Methodica Avium & Piscium* (1713). The original folio of just over 300 pages had been reduced to an octavo, but with additions it still extended to 200 pages. While the natural system of Willughby and Ray was not received favourably by all at the time, it was the most comprehensive and complete of its kind then and for at least another 50 years. It also became an important influence on Linnaeus when he applied his natural system to birds; indeed, he did not improve on it overall.

Johann Ferdinand Adam von Perna (1660-1731) was interested in the comparative behaviour of birds. He had been influenced by the studies of Schwenkfeld in devising a classification system of birds based on behaviour, but he recognized more categories, and he confined the results of his ideas to his own observations. While he may not have had much success with classification from a systematic perspective, his research produced other valuable results such as the discovery of territory in birds, instinctive behaviour, such as feeding at the nest and why birds migrate, and remarks on the role and meaning of bird song. He elaborated his ideas in his *Unterricht, Was mit dem lieblichen Geschöpf, denen Vögeln, auch ausser dem Fang, nur durch Ergründung deren Eigenschaften und Zahmmachung oder anderer Abrichtung man sich vor Lust und Zeitvertreib machen könne* (1707, revised 1716, supplement 1720). However, interest in bird behaviour as opposed to systematics, i.e. popular vs scientific ornithology, diverged for about 200 years before the importance of the interrelationships of these aspects of ornithological study was fully appreciated (Fisher 1954; Davis 1994).

Carl Linnaeus (1707-1778), or von Linné from 1761, disappointed his family by refusing to join the clergy, and he eventually studied medicine in Uppsala, Sweden, but with a great interest in botany. In 1735, after adventurous travels in Lapland, he went to the Netherlands to further his studies. He was already interested in devising a new system of classification and soon found inspiration from the many natural-history collections he saw there. He also inspired interest in his system, with its sequence of Classis, Ordo, Genus, Species and Varietas, and was sponsored for the publication of the first edition of his *Systema Naturae* (1735), then only consisting of several large sheets. His hierarchical concept of categories of relationship was the real improvement on Willughby and Ray, who had used Genus in the sense of Aristotle so that it was interchangeable with the refined Linnaean categories from Class to Genus. Over the next 20 years, inspired by the work of friends and the fame generated by the appearance of his simple but useful method, he developed and refined his natural system. By the sixth edition of *Systema Naturae* (1748), the diagnoses of genera and species were much improved. The real inspiration of Linnaeus was developing a simple but workable system, and this was its great appeal. For birds he recognized six orders, using the

beak and foot as points of reference: 1. Accipitres (birds of prey, owls, parrots); 2. Picae (woodpeckers, hornbills, cuckoos, hoopoes, and also crows and crow-like birds); 3. Anseres (swimming birds); 4. Scolopaces (fissiped waterfowl); 5. Gallinae (ratites, pheasants, bustards and coots); 6. Passeres (all other passerines, but also pigeons, hummingbirds, etc.). The old division of landbirds and waterbirds was gone. The system as we know it today was finally published in the 1750s.

To some naturalists and zoologists in the mid-eighteenth century the attraction of the Linnaean system was not so much his classification as his strict methodology, which could be varied and played with. Also at this time, several large works illustrating birds in colour but in no particular system became popular. Prominent amongst these were the *Natural History of Carolina, Florida and the Bahama Islands* (1731-1743) by Mark Catesby (1682-1749), the first major work on North American birds, and *A Natural History of Birds* (1743-1751) by George Edwards (1694-1773), both authors enjoying the patronage of Sir Hans Sloane (Feduccia 1985; Mason 1992; McBurney 1997). Pierre Barrère (1690-1755) combined these developments by offering a confusing system in his *Ornithologiae specimen novum...in classes, genera et species, nova methoda, digesta* (1745). His approach, mixing large and small birds, worked well as a method for fitting different-sized birds into cabinets! Others, like Barrère, using Linnaeus as the point of reference, could produce different results, such as the *Historia avium prodromus* by Jacob Theodor Klein (1685-1759) in 1750, and *Avium genera* by Paul Heinrich Gerhard Möhring (1710-1792) in 1752, but these publications did not detract from the progress of Linnaeus. Also, collections were increasing in importance (Mearns & Mearns 1998), most famously that of Sir Hans Sloane, willed to the nation on his death in 1753 and forming the genesis of the British Museum, first opened in 1759 (Stearn 1981; MacGregor 1994). The search for a natural system was gaining pace and seemed to be in sight at last.

### *The first wave: philosophy and typology (1758-1850)*

The natural system of Linnaeus, as we know it today, dates from the tenth edition of his *Systema Naturae* (1758), published when Linnaeus was at the height of his powers. The tenth edition is also the starting point for zoological nomenclature, when the binomial (or binominal) method, a single name each for genus and species, was first consistently applied to all animal groups, although universal acceptance was not to come till over a century later, after much controversy and debate. Linnaeus's inspiration for using only two names came to him when he was preparing an index. He had first tried the method for several animal groups, including birds, in his *Museum Adolphi Friderici Regis* in 1754, after successfully applying it to plants in his *Species Plantarum* in 1753 (eventually the official commencement date for botanical nomenclature). Linnaeus still retained six orders for birds, but by the tenth edition he had rearranged some of the genera within them, such as moving parrots and hummingbirds to Picae, and ratites and bustards to Grallae (formerly Scolopaces). Although Linnaeus's manic depressive personality became increasingly pathological in his later years, he maintained a high opinion of his achievements, reinforced by the responses to his works. He considered his *Species Plantarum* "the greatest in the realm of science" and his *Systema Naturae* as a "masterpiece that can never be read and admired enough", and he even published anonymous reviews of his own works (Goerke 1973). Linnaeus also saw his system as the greatest representation of nature as God's creation, but he could also react against his work by feeling that hate and envy were his rewards (Lindroth 1994). The first to spread the new wave of the natural system of "God's registrar" were his students, starting as early as 1745; all were sent with orders and instructions, and they were designated by Linnaeus as his "Apostles" (Koerner 1999). Some produced important works, while others perished in remote corners of the globe. The most famous student was Daniel Solander (1733-1782), who was one of the naturalists on the first great voyage of exploration by Captain James Cook (1728-1779) in 1768-1771 (Duyker 1998); this was also the first important expedition for natural history. Linnaeus is best known today for his botanical works (the "Prince of Botanists"), as his deficiencies in zoology are apparent, but his real legacy is the workable and adaptable system of binomial nomenclature still used today.

The ripples of the new wave of classification using the binomial system soon spread out from Sweden. For birds it was adopted as early as 1763 by Erik Pontoppidan (1698-1764), in an appendix of his *Dansk Atlas*; in 1764 by Morten Thrane Brännich (1737-1827) in his *Ornithologia Borealis*; also in 1764 by Peter Simon Pallas (1741-1811) in his *Adumbratiunculae* to A. Vroeg's *Catalogue raisonné*; and others such as Johann Reinhold Forster (1729-1798) from 1767, and both Thomas Pennant (1726-1798) and Giovanni Antonio Scopoli (1723-1788) from 1769. Marmaduke Tunstall

(1743-1790) was the first to apply Linnaean names to British birds in his *Ornithologia Britannica* (1771), but he kept Willughby and Ray's division of land- and waterbirds. The acceptance of the system in Germany was popularized by Philipp Ludwig Statius Muller (1725-1776) in a German edition of Linnaeus's *Systema Naturae* appearing from 1773, including a supplement in 1776. This supplement contained the first large application of binomial nomenclature to species known but not yet incorporated into the Linnaean system. Mathews (1925) pointed out that "Sharpe suggested he was colour blind", no doubt due to a number of unidentifiable birds named. However, he may not be entirely to blame, as he merely translated his descriptions of new species into German from a 1772 Dutch abridgement of Linnaeus by Pieter Boddaert (1730-1796), who only gave Dutch names to those birds additional to Linnaeus (Cassin 1864). As Cassin demonstrated, one needed to consult Boddaert for the exact source of names from Buffon, as Statius Muller simply stated "Buffon", if based on that work (see below).

Mathurin Jacques Brisson (1723-1806) was the curator of the large French private museum of natural-history objects, including not only bird specimens but also nests and eggs, belonging to René Antoine Ferchauld de Réaumur (1683-1757), who published important works on insects. In working out the arrangement of this diverse collection, Brisson sought to adapt Linnaeus's system, which he first applied to mammals in 1756, but its simplified approach made him all too aware of its deficiencies in characterizing groups and species. In 1760 he published his *Ornithologie* in such detail that it filled six volumes and 4000 pages. It was a comprehensive summary of all known species, based not only on previous sources and de Réaumur's extensive holdings, but also on material studied in several other private collections in France. Much of interest was offered by de Réaumur's correspondents, notably Pierre Poivre (1719-1786), who also sent some specimens to other private French collectors. He collected in India, South-east Asia and Madagascar during clandestine missions to smuggle spice plants from the Dutch East Indies to Mauritius in 1751-1756, in spite of losing his right arm in 1745 during an earlier voyage to South-east Asia (Stresemann 1952; Ly-Tio-Fane 1994). Of some 1500 species described, Brisson was able to add 320 determined as new from the specimens examined. Brisson, influenced by de Réaumur, could not reconcile his classification with the brief, but broader definitions of Linnaeus and increased the number of orders from 6 to 26, with subdivisions where required, and defined a large number of new genera. He kept his key characters simple, particularly the beak and claw, to minimize errors. With care and attention to detail he made few mistakes and provided a classification nearer to modern ones than anything in the following 80 years.

For all his attention to detail, Brisson did not adopt the binomial nomenclature system of Linnaeus's tenth edition but instead had been using the sixth edition. By the time he could use the tenth edition, four volumes of his work had already been printed and, although he was able to indicate his awareness of the tenth edition in the last part of the work, it was too late. He was not a strict follower of other systems, but instead created his own elaborate classification of birds, which was criticized and was not followed, because, unlike that of Linnaeus, it was hard to learn. While he delineated his higher categories and species descriptively, he used a single term for his well-defined genera. These were eventually recognized and accepted after much doubt and debate not only about the problem of the non-binomial nature of Brisson's work but over the exact number of genera that could be used (Allen 1910; Bock 1994). Meanwhile, de Réaumur had willed his collection to the *Académie Royal des Sciences*, in order to keep it out of the hands of his great rival, the Comte de Buffon. Nevertheless, by 1760, Buffon's influence was such that he ensured de Réaumur's collection made a valuable addition to the *Cabinet du Roi*, of which Buffon was in charge; in truth, this transfer made sense because the *Académie* did not have the facilities to manage such a large collection. As a result, Brisson was out of a job and soon left ornithology after such a brilliant debut (Farber 1982), later becoming a teacher of physics. Linnaeus subsequently incorporated Brisson's new species into his system, in his twelfth edition (1766).

George-Louis Leclerc (1707-1788), Comte de Buffon from 1772, became the leading natural historian in France in the second half of the eighteenth century. He began his rise in scientific circles, as was typical of the day, by currying favour over potential rivals, in this case, by assisting with a blackmail scheme against the ex-husband of a duke's wife. Later, in 1749, he began his great work, the *Histoire naturelle, générale et particulière*, reaching 36 volumes by his death in 1788, though the series eventually finished with 44 in 1804. These included the nine volumes (Vols 16-24) of his *Histoire naturelle des oiseaux*, which appeared from 1770 to 1783. They were supplemented by 973 of the 1008 coloured plates of what became known as the *Planches enluminées*, issued from 1765 to 1783 in 42 parts and two sizes (Heilbrun 1952) and which gained

great popularity. Buffon had been director of the *Cabinet du Roi* since 1739 and his great work, with some of the text and all of the plates contributed by members of his staff, was originally intended to provide a catalogue to the collection. Although the collection was small when he began, he had a very different philosophical approach to his subject. He opposed the nomenclatural systems as exemplified by Linnaeus. Instead, he saw the task ahead as surveying the great relationships of nature, beginning with the development of the earth and all life but not hindered in his interpretations by the hand of God and traditional doctrines, i.e. the fixity of species (typological species concept). In seeking other explanations, including hints of evolutionary ideas mixed with Aristotelian theory, his writings may have seemed impressive but their superficiality was apparent to many who read his explanations. His attempts to interpret the influence of time, climate and diet on species required groupings of clearly unrelated species around the world, which then had to be climatic varieties. Pierre Sonnerat (1748-1814) was an early critic who in 1776 observed that he could not reconcile Buffon's ideas to what he had seen on islands in the Philippines. On the other hand, the Italian Jesuit, Giovanni Ignazio Molina (1740-1829), in his *Saggio sulla storia naturale del Chili* (1782), followed Buffon's ideas by considering many birds in Chile as varieties of European species.

Buffon, with his holistic approach to an understanding of nature, placed great importance on an understanding of the habits of animals in the wild; he was labelled as the "French Pliny" by some later workers. He developed a network of correspondents, bestowing them with honorific titles, and reaping the benefits for his collection and volumes. As he ordered his system from the most to the least interesting of animals to man he used this approach in organizing the classification of mammals and continued with this method for birds. By the time he was planning his volumes on birds in the 1760s the de Réaumur collection arrived at the right time to supplement the meagre holdings of the *Cabinet du Roi*. Several correspondents of de Réaumur now supplied material to Buffon and enhanced his existing, extensive network. Others were encouraged to go out and gather information from exotic locations, fulfilling a role similar to Linnaeus's "Apostles". For example, Charles-Nicolas Sigisbert Sonnini de Manoncourt (1751-1812) based himself in Cayenne and sent a large collection with notes. The Scottish explorer James Bruce (1730-1794), also supported by Buffon, was eager to share his findings from his Ethiopian adventures when passing through Paris in 1773 (Bredin 2000).

Even his critic, Sonnerat, supplied him with material from his Asian travels, beginning in 1771-1772 when Sonnerat's godfather, Pierre Poivre, sent him to New Guinea, as part of a new secret mission for spice plants. In spite of his own useful records on birds he could not resist adding others from elsewhere to enhance the value of his work. Amongst such embellishments were specimens and drawings from the naturalists on Cook's first voyage, obtained when he met them in Cape Town in 1771, and others from Philibert Commerson (1727-1773), the naturalist who accompanied the circumnavigation of the globe by Louis Antoine de Bougainville (1729-1811) in 1766-1769 and later remained on Mauritius. This material included three penguins, which Sonnerat claimed to have seen in New Guinea waters, whence the Gentoo Penguin is named *Pygoscelis papua*. The most famous addition, however, was the Australian Laughing Kookaburra, thus named *Dacelo novaeguineae*, although never recorded from New Guinea (Ly-Tio-Fane 1976). The great popularity of Buffon's works led to numerous editions and translations, stimulating an appreciation of nature in many quarters, notably in Italy. He wrote for the dilettante and was enamoured of his own style (over substance), although this was to some extent understandable: the available material was limited, so he felt he had to pad out his writings with speculations on the significance of as much as he could highlight. He had some interesting ideas but these were not greatly developed and were mixed with misinformation. All things considered, he was doing what he could with what was on hand and, as he was trying to cover everything, the criticism of superficiality is understandable (Roger *et al.* 1997). On its own merits, Buffon's work on birds may have contained more deficiencies than Brisson's, but, as noted in an earlier period, the best work is not necessarily the most popular. Although Buffon's ideas on classification continued to survive, they were increasingly overshadowed by Linnaeus's natural system. When later Linnaean authors named birds based on Buffon's work, the focus was on the plates rather than the text, although the information in the relevant text was acknowledged. Therein lies the lasting value of Buffon, as the plates are the types for a large number of bird names.

Thomas Pennant, a prominent English naturalist, was well known for *The British Zoology* (1761-1766, and later editions). He was familiar with the work of Linnaeus but preferred to use English names and, as in his *Genera of Birds* (1773), he was a follower of Willughby and Ray (Mullens 1909a). He was also a friend and corre-

spondent of Linnaeus and had experimented with Linnaean names as early as 1769 in the *Indian Zoology*, using selected paintings brought to England in 1759 by Joan Gideon Loten (1710-1789), a former Dutch governor of Ceylon (Allen 1908). However, after a single part of 12 plates and text was issued, Pennant lost interest and passed the material to Forster who produced a German version with names after Linnaeus in 1781. After his *Arctic Zoology* (1784-1787), Pennant revised the Indian work, based on Forster, with Linnaean names, in 1790. Forster then revised his own edition again in 1795 (Hoare 1976). Pennant's inclination and influence was to keep an interest in England in the classification system of Willughby and Ray, but the influence of Forster, in particular, led him to combine it with the classification of Linnaeus. This mix of systems could not continue for long.

John Latham (1740-1837) dominated ornithology in England for 50 years. With access to museum collections and other resources, he first attempted a summary of all the birds of the world in *A General Synopsis of Birds* (1781-1785), including much new material recently arrived from voyages, notably those of Captain Cook. In this, he retained the basic classification system of Willughby and Ray and used English names (Allen 1951a). As with the influence of Buffon in France, the English were not yet completely ready to accept the new methodology. Like Pennant, Latham also dabbled with Linnaeus. In a tabular list of British birds, added in the first supplement to his *Synopsis* in 1787, he listed names in the Linnaean system. Latham's reluctance to embrace the Linnaean system fully had its consequences. Linnaeus himself set the precedent when he claimed the new species of Brisson in 1766, a trend duly followed by Statius Muller in 1776, using mostly Buffon. In the 1780s the pace increased, first with Forster in 1781 in his list of Asian birds appended to his revision of Pennant's *Indian Zoology*. In 1783 Boddaert latinized the names in an index of Buffon's plates, but his delay in applying the Linnaean system to the new species meant that Statius Muller took the credit for those covered in his earlier work of 1772. In 1786 Scopoli did the same for the birds listed only by French names in Sonnerat's two voyage reports, but he found it difficult to make them all fit in and this led to some odd combinations, such as a quail named in the genus for orioles. Lastly, Johann Friedrich Gmelin (1748-1804), an "industrious but indiscriminate and incompetent compiler", according to Coues (1880), pulled it all together in his so-called thirteenth edition, actually the fourteenth if associated with Linnaeus (Iredale 1958), of *Systema Naturae* (1788-89), augmented by the many new species from Latham's volumes.

Realizing what was happening, Latham tried to make up for lost time with his own Latin summary of his work in 1790 with his *Index Ornithologicus*, delayed to include new discoveries, most notably the Emu (*Dromaius novaehollandiae*), from the new colony in Australia. Latham enjoyed access to the earliest discoveries coming from Australia, but the next batch to arrive went to his rival at the British Museum, George Shaw (1751-1813). While in his *Index* he reluctantly had to acknowledge Gmelin's names, he did not accept them all, but the names used today that date from the *Index* are for the additions since his *Synopsis* was published. A decade later, particularly with all the new material arriving from Australia, Latham could once more outdo his rival so he decided to update his work with a second supplement, in English and Latin editions. This time the Latin edition appeared first, in 1801, but the English edition apparently was delayed until 1802 (Browning & Monroe 1991), with the remarkable Superb Lyrebird (*Menura novaehollandiae*) arriving just in time. Latham had apparently learned his lesson. From the 1790s Linnaeus's system was widely used in England, although the Willughby and Ray division of land- and waterbirds lingered. In his 80s Latham again attempted to summarize all known birds, an increasingly difficult task, in his *A General History of Birds* (1821-1828), but the revision of the Latin *Index* was still unfinished when he died at 96 in 1837 (Mathews 1931). It was the last vestige of the Willughby and Ray system. Latham's reversion to his old methods once more allowed new species to be latinized by others, and this time it was James Francis Stephens (1792-1852) in the later volumes continuing his late rival Shaw's *General Zoology* (1816-1826), who claimed a large share of them.

The death of Buffon in 1788 encouraged the emergence of followers of Linnaeus in France (Spary 2000). Within a year the botanist René Louiche Desfontaines (1750-1833) had taken the first steps by naming several new species collected on his travels in the Barbary States (Algeria). The Abbé Joseph Pierre Bonnaterre (1747-1804) began the *Tableau encyclopédique et méthodique: Ornithologie* in 1790 but with the disruption of the French Revolution this work was not completed until the 1820s (by Vieillot). The great comparative anatomist Baron Georges Leopold Chretien Frederic Dagobert Cuvier (1769-1832) followed Linnaeus in his conservative classifications, beginning in 1798, but birds were not of any particular interest to him. In 1799 Bernard Germain Étienne de la Ville-sur-Ilлон, le Comte de Lacépède (1756-1825), using the beak-foot approach, changed the 6 orders and 81 genera of Linnaeus to 10 "divi-

sions", 51 "orders" and 130 genera. However, this system had no lasting influence, as it created the same types of anomalies as found in works before Willughby and Ray. François Marie Daudin (1776-1804), in his *Traité élémentaire et complet d'ornithologie, ou histoire naturelle des oiseaux* (1800), attempted to provide a complete handbook of ornithology. He provided a Linnaean framework and combined it with the best ideas of Buffon in seeking to understand the whole bird, with much useful information on anatomy and behaviour incorporated, including indications of possible new directions of research, especially in behaviour.

In Germany, Pallas, famous for his Russian explorations supported by Catherine the Great (1729-1796), had already tried to create a synthesis of the Linnaean and Buffonian schools in his later work, particularly in his major faunal study of Russia (1811-1814). Johannes Hermann (1738-1800) in his *Tabula affinitatum animalium* (1783) introduced to birds the concept of showing the relationships of genera by their degree of affinities, expressing the results by linking them in horizontal or vertical rows. Hermann's work had little influence, although followed for a time by Johann Friedrich von Brandt (1802-1879), working in Russia. Blasius Merrem (1761-1824) planned to develop a true natural classification of birds by studying their internal and external characters, as well as their entire life histories. In 1788 he only got as far as introducing and demonstrating his ideas in his *Versuch eines Grundrisses zur allgemeinen Geschichte und natürlichen Eintheilung der Vögel*. Later, he was able to apply some of his ideas to a classification in his *Tentamen Systematis naturalis Avium* (1816). However, in 1788 Germany was not yet ready for such new methods. There were other, philosophical influences, as well as another rise in the popularity of well-illustrated books. In Germany and England, for example, this meant multi-volume works on local birds, but in the France of Napoleon, attention turned to colourful, exotic birds. This time there were attempts at systematically arranging birds for their presentation.

François Levaillant, or le Vaillant (1753-1824) was the most famous ornithologist at the turn of the nineteenth century, commencing three large, illustrated works simultaneously in 1801, including the first major monograph on any bird family, the parrots (Bruce 1991). His fame rested on explorations in southern Africa, culminating in an incomplete *Histoire naturelle des oiseaux d'Afrique* (1796-1813), the first comprehensive regional work on birds outside Europe. In spite of the many excellent observations provided in this work and his two travel books, they were marred by the inclusion of species recorded by Levaillant but later shown to be either not southern African, artefacts (faked, composite specimens), or completely fictitious (Sundevall 1857). This was blamed on his use of other writers or editors to embellish the text: apparently his father edited the first book and the second was entrusted to Casimir Varon, a man of letters, who "permitted himself greater liberties... than Vaillant Sr had done" (Bokhorst 1973). Although branded a liar by later workers in South Africa, it was not unusual at the time for an author to take advantage of what was available to enhance his work, as noted above for Sonnerat. In Levaillant's case, based on his own work and the opinions of others, he was "a vainglorious man who considered he had been unjustly neglected by the learned world of his day" (Winterbottom 1973). The classification used in his works was modelled on Buffon's methods as Levaillant despised the Linnaean system. He thus offered the last great field of bird names to be harvested by followers of Linnaeus, further undermining the credit due to his important contributions (Rookmaaker 1989).

Louis Jean Pierre Vieillot (1748-1831) was frustrated by his slow progress in the scientific world, so he emigrated with his young family to the French colony of Santo Domingo (Hispaniola) to seek new business opportunities and pursue his interest in birds. When the French Revolution began in 1789 he went to the USA for several years to avoid military service, returning to Santo Domingo in the 1790s. He originally planned to gather material to offer to Buffon, but the latter advised him to perform his own studies. He set out for France with his family in 1798, but lost his wife and three daughters to yellow fever on the way and arrived alone. He soon began working with several artists and, mostly using his own material gathered in North America and the West Indies, produced a series of large illustrated works from 1800 to 1809 (Ronsil 1957). In the last of these, the *Histoire Naturelle des oiseaux de l'Amérique septentrionale* (1807-1809), he began to use the Linnaean system. These publications also provided him with his first opportunity to develop his own ideas on classification. With the help of Charles Dumont de Sainte-Croix (1758-1830), who provided him with an income, he further developed his ideas in the then popular series of dictionaries of natural history, to which Dumont was also a contributor.

Bernhard Meyer (1767-1836), a court councillor to the Prince of Isenburg, was also a doctor who found more time for ornithology by taking over an apothecary business. He became a leading figure in the study of German birds and in a series of

works from 1810, began applying his ideas on using strict Linnaean principles. At this time of great activity for German ornithology, this influence was important because it was also an influential time for the school of German “natural philosophy”, whose leading proponent was Lorenz Oken (1779-1851). Oken summarized these ideas in his *Lehrbuch der Naturgeschichte: Zoologie* (1815-1816), but the concepts deriving the natural world from the intellectual, with all designs and levels of nature graduating towards the ultimate ideal, the human form, were taking the concept of “artificial” vs “natural” systems back to the Middle Ages. There were critics, but also followers, and Oken also used his journal, *Isis*, to develop his ideas further, although it finished in 1848, when Oken could no longer continue it.

Johann Carl Wilhelm Illiger (1775-1813), originally working in entomology, became involved with ornithology when new collections from the recently opened country of Brazil arrived in Germany (Stresemann 1950). One of his concerns was establishing the correct terminology of classifications and for birds this was provided in his *Prodromus systematis mammalium et avium* (1811), where he attempted to rework Linnaean principles for classifications at all levels. He was the first to seek precise order in nomenclature, even going as far as to propose to outlaw names he considered as barbarisms, a practice that gained a few followers, particularly in Germany. The practice lingered for many years, with the last vestige as late as 1890 (Heine & Reichenow 1882-1890), in spite of the famous attack on the subject by Allan Octavian Hume (1829-1912) in his review of a parrot monograph; this was *Die Papageien*, published by Friedrich Hermann Otto Finsch (1839-1917) in 1867-1868. Hume complained about “a certain section (chiefly Continental) of naturalists” who would change names because they were not classically formed, thus cheaply creating new names for themselves: “Let us treat our author as he treats other people’s species. ‘Finsch!’” contrary to all rules of orthography! What is that “s” doing there? “Finch!” Dr. *Fringilla*, MIHI! Classisch gebildetes wort!!!” (Hume 1874a). Hume was in turn attacked for his attack, but Finsch changed his ways and the two of them soon established friendly exchanges (Hume 1874b).

Illiger further developed his ideas in 1812 with a paper entitled *Tabellarische Uebersicht über die Vertheilung der Vögel über die Erde*, where guidelines on delineating the relationships of birds were demonstrated, but it was not published until 1816. It was also the first biogeographical study of birds. He was also seeking to develop a new method in opposition to what he saw was happening in France, where the considerable influence of Cuvier was later consolidated in the first of his two editions of his *Le règne animal* (1816-1817, 1829-1830); this work was later expanded by his “disciples” from four to 17 volumes (1836-1849), and also translated into English, German and Italian (Farber 1982). Illiger recognized 7 orders, 41 families and 147 genera. He was the first to establish the concept of the family category for birds as we know it today, although after being refined and standardized by later workers (Bock 1994). Illiger, dogged by illness for years, tragically succumbed to a haemorrhage at an early age when he had barely begun his work, but his concern not to overload the Linnaean system with names was ignored by all but a few followers.

Coenraad Jacob Temminck (1778-1858), a member of a wealthy Dutch family, was first influenced by Levaillant in developing his ideas in ornithology, as he came to know Levaillant through the sponsorship of his explorations by his father, Jacob Temminck (1748-1822). During his honeymoon in Germany, in 1804, he stayed with Meyer, who influenced his ideas and encouraged him to adopt the Linnaean system. His first book was a catalogue of his collections, in 1807, in which he followed Linnaeus (Stresemann 1953). He was also working on monographic studies of pheasants and pigeons. By chance, at this time in Paris, Pauline de Courcelles (1781-1851), a gifted artist, planned to paint pigeons and needed someone to write a text. Temminck agreed and began at once, with the first part of what became a sumptuous, illustrated, but incomplete volume, *Les Pigeons* (1808-1811), appearing within months. The artist became Madame Knip in 1808 and decided to swindle him by claiming credit for the whole work, beginning with the title of the ninth part. She wanted to win favour with the new empress and succeeded. Temminck was sent some copies with the correct title, but he found out about the swindle when he visited Paris (Coues 1880; Mees 1975). The two parted in anger, although they eventually reconciled some years later. Temminck abandoned the larger project and instead published his monographs in a cheaper version, the three-volume *Histoire générale des pigeons et des gallinacées* (1813-1815), with an explanation of what happened. The influence of Meyer’s work, amongst others, also inspired Temminck to produce the first edition of his *Manuel d’ornithologie, ou tableau systématique des oiseaux qui se trouvent en Europe* (1815). His classification of birds followed the Linnaean system which was expanded in the second edition of his *Manuel* (1820, supplements 1835, 1840). These were very influential and became the standard work on European birds for many years. In 1820 he

was also inspired to begin another large, illustrated series as a supplement to the work of Buffon, and this was to make up five volumes by its end, in 1839 (Dickinson 2001). This work mainly illustrated some of the new birds arriving at his museum at Leiden, but Temminck's pace slowed and much material went unstudied for many years, as he locked away many specimens that he never found time to study.

In the meantime Vieillot, apparently ignorant of Illiger's reforming work, had developed a new classification of birds to express their natural relationships as early as 1813 but delays meant that he finally rushed his *Analyse d'une nouvelle ornithologie élémentaire* into print himself in 1816 to antedate Cuvier's forthcoming work. In it he recognized 5 orders, 57 families and 273 genera, including the merging of the Picae and Passeres into his "Sylvicolæ"; some of his new genera were also named by Cuvier, but too late. In response to criticisms, this classification was reworked in his numerous articles in the second edition of the *Nouveau dictionnaire d'histoire naturelle* (1816-1819), where many new species were named using earlier works, particularly on South American birds, and also collections in Paris from the recent French scientific voyages; as the museum staff in Paris refused to help him, he took his descriptions of new birds in the collection from the public galleries. These numerous articles were collected and revised when he resumed work on Bonnaterre's *Tableau encyclopédique*, which had been incomplete when it ceased in 1791, the new edition appearing in three volumes in 1820-1823. Although Vieillot was seeking a natural classification, he was immediately criticized by Cuvier and also by Temminck, who presented his views in a pamphlet, *Observations sur la classification méthodique des oiseaux, et remarques sur l'Analyse d'une nouvelle ornithologie élémentaire par L. P. Vieillot* (1817). Temminck considered it vague and artificial, particularly because of the emphasis on foot structure and overlooking Illiger and other recent works, especially his own. Of Vieillot's numerous new genera, Temminck complained of his pilaging and plagiarizing of many of those of Illiger and Cuvier in particular, and concluded by urging others like him to abandon this sterile work.

Temminck elaborated on his views in the first volume of his revised *Manuel* (1820), where his attacks on Vieillot were also extended to Vieillot's dictionary articles, including his criticisms of Temminck in response to his pamphlet. These were regarded as puerile in view of his pretentious work, an overreaction to his own faults, displaying an ignorance of German works and embarrassing for his unnecessary and badly created names, stealing many already given by Illiger and others. However, Temminck's focus, too, was on developing a natural classification. As a result, apart from his reactions to Vieillot, he attempted to bring together everything yet published of worth, disregarding Illiger's concerns for nomenclatural purity, and finding problems with more than just Vieillot's classifications. His bile towards Vieillot was also extended to Gmelin's "miserable compilation" unworthy of association with Linnaeus. In spite of such concerns, Temminck was committed to developing a carefully constructed classification out of the increasing chaos of the time and in this he anticipated Strickland's later concerns. His natural system contained 16 orders and 201 genera, with the family category almost ignored. While he reluctantly accepted some of Vieillot's new names, he gave preference to Cuvier's later names in some cases and because of the influence of this classification, Temminck also created a little chaos of his own. While the younger Temminck would achieve success, Vieillot spent his last years blind and in poverty (Olivier 1965). In spite of the hostility he endured in his lifetime, he succeeded in publishing much useful work that was greatly appreciated in later times.

Christian Ludwig Nitzsch (1782-1837) was the first of a group of anatomists to make important contributions by studying particular characters and how they affected the relationships of various groups and of the higher categories of birds. He is best known for his studies on pterylography, from as early as 1806, but his major work on the subject was published posthumously (1840, translated into English 1867). He also wrote, for example, on osteological characters and the nasal glands, and in his extensive study of the carotid arteries, *Observationes de Avium arteris carotide communi* (1829), he used his findings with other characters to propose his natural classification; this was later modified in his work on pterylography. Henri Marie Ducrotay de Blainville (1777-1850), Cuvier's successor, began his studies of the sternal characters of birds in 1815 to find a natural classification. His rearrangements of the higher categories were influential, and he split passerines into "true" and "false" groups, and importantly, he separated *Menura* from the gallinaceous birds (1821). Felix Louis L'Herminier (1779-1833), from the island of Guadeloupe, was a pupil of de Blainville and further developed the study of sternal characters, but also combined them with other anatomical data in developing his natural classification (1827). There are some similarities in how L'Herminier and Nitzsch worked out their higher categories and they may have developed some of their ideas together. There may, too, have been some influence from the 1816 classification of Merrem, also using anatomical data.

The main results of these and other anatomical investigations of this period of activity were in developing the restructure of higher categories closer to those recognized today. For example, in 1829 Nitzsch separated swifts from swallows, placing them nearer the hummingbirds.

Nicholas Aylward Vigors (1785-1840), a politician by profession, was at the heart of ornithological activity in London. He was influential to many at the time, notably helping to start John Gould (1804-1881) on his way to producing his famous bird folios (McAllan & Bruce 2002). This influence also took some ornithologists in a different direction for a while, when he developed a classification for birds based on what became known as the Circular or Quinarian System. This system was introduced by William Sharp MacLeay (1792-1865) in *Horæ Entomologicæ* (1819-1821), when he found that philosophical ideas of the time on the concept of divine order in the universal chain of beings could be expressed geometrically and numerically. As with the German natural philosophers of this period, who also had influenced MacLeay, old ideas were new again. Vigors took MacLeay's ideas further in applying them to birds in articles published from 1824 to 1830, particularly his 1825 essay, *Observations on the Natural Affinities that connect the Orders and Families of Birds*. Here it could be shown that all natural groups form five circles of equal rank, with each subdividing into five, thus five orders, five tribes [suborders], five families (O'Hara 1988, 1991). He also applied his ideas to a major report on Australian birds, in 1826, containing many new species, but only the first part was published (Vigors & Horsfield 1827). His classification may be ignored but he certainly helped standardize family names for birds.

William Swainson (1789-1855) developed an early love of natural history through his father's interest in insects. He wanted to travel and managed to visit various parts of the Mediterranean during military service in the latter years of the Napoleonic wars (1807-1815). As Brazil had recently opened to foreigners, he visited several areas to study and collect birds and other natural history objects in 1816-1818. He began publishing on birds and wanted to apply his drafting skills to illustrating birds. He was encouraged to try the new process of lithography and produced and published the first lithographic plates of birds in 1820, subsequently continuing with several series, mostly of birds and shells (Jackson 1975). Through Vigors and his work on the subject, Swainson became acquainted with the new circular system and embraced the concept with much enthusiasm. He supported and defended it at every opportunity with such fervour that by 1827 he had fallen out with Vigors (and later claimed credit for some of Vigors's new names) and MacLeay. Like Vigors he adapted and modified the scheme, but, while the circular arrangements were still placed in groups of five, he refined them with subdivisions of three and two to make the five. To Swainson the natural system meant finding the appropriate placement of each species or higher category according to their affinities and analogies (Knight 1981). In cases where he determined that there were gaps in the groups of five, these were to be filled later by an as yet undiscovered taxon. With failed investments, the death of his wife in 1835, and five children to raise, as well as his missing out on a coveted position at the British Museum, he turned to hack writing for a living, and quickly contributed volumes to two popular series of the day. These works gave him a great opportunity to develop his version of the circular system. He summarized his ideas on birds in his *On the Natural History and Classification of Birds* (1836-1837), and last wrote on the subject in *Flycatchers* (1838). After 1838 his critics in England had finally won the field, and Swainson's authority and reputation as an ornithologist were seriously damaged, if not completely destroyed. In defeat and dire financial straits, Swainson emigrated to New Zealand, an embittered man, in 1840 and, although he lived another 15 years and retained his interest in birds, he published nothing further on them. In New Zealand he had a slight influence, however, both good and bad, on a young Walter Lawry Buller (1838-1906), later to become the great authority on the birds of New Zealand (Galbreath 1989).

Hugh Edwin Strickland (1811-1853) was a geologist by profession and the son-in-law of Sir William Jardine (1800-1874), a well-known ornithologist, who, amongst other things, produced the first bird journal in England. Strickland is known for his reports on developments in ornithology, was a stern critic of the philosophically based classifications, and played a major role in the defeat of the Quinarians. However, in spite of the success of eliminating the Quinarians from England, similar philosophical classifications continued in Germany for another twenty years, although with little influence. Meanwhile, Strickland continued with his strong views on classification and nomenclature until his tragic early death: hit by a train, while inspecting a rock cutting near the railway line. His most important contribution towards bringing order out of chaos was his development of the first modern code of nomenclature in 1842, based on the twelfth edition of Linnaeus of 1766, but with some compromises to appease the critics. It was revised in 1866, while other codes emerged. By the 1870s

there was strong support for fixing nomenclature on the tenth edition of Linnaeus of 1758 and this became the new starting point, beginning with the code of the American Ornithologists' Union (1886). However, in Europe, particularly England, the twelfth edition as the starting point lingered for 20 years in most standard works. One of Strickland's compromises was the acceptance of Brisson's genera, even though they were published in 1760. This was influential in moving opinion towards the tenth edition, as this would not require any exceptional cases (there was also the problem of Brisson's mammal genera of 1762). In 1895 the attempt to unify the competing codes began, with the first international rules appearing in 1905, and the first code as we know it today, the International Code of Zoological Nomenclature, eventually appearing in 1961, with the fourth edition coming out in 1999. So far, only categories up to the level of family name are covered by the code. After being in and out of favour over many years, Brisson's bird genera were finally accepted in 1955 (Bock 1994; Melville 1995; ICZN 1999).

Johann Jacob Kaup (1803-1873), unsuccessful as an assistant to Temminck in 1825, returned to his home town of Darmstadt in Germany and spent his career at the local museum (Heldmann 1955). He published a preliminary classification of birds as early as 1829, and presented his views in more detail in his *Classification der Säugethiere und Vögel* (1844). He followed the philosophy of Oken and also used the mystical number five, where the systematic categories were based on their developments from one each of five anatomical characters, five sense organs and five areas of the body. Instead of circles he used pentagrams, and he maintained these ideas in later works. Amongst several attempts to develop philosophical rules of classification, the most significant work in addition to Kaup's was carried out by Heinrich Gottlieb Ludwig Reichenbach (1793-1879) who produced a series of publications from 1834 to 1863 known under the general title of *Das Natürliche System der Vögel* (see Meyer 1879). He followed Oken more closely and retained the division of categories according to the number four. In following this method, he could claim that his systematic works were the most complete natural histories of the successive groups covered. Leopold Fitzinger (1802-1884), primarily working in herpetology, adapted Kaup's philosophy in his *Über das System und die Charakteristik der natürlichen Familien der Vögel* (1856-1865) and placed birds amongst the other vertebrate classes in five parallel rows for a continuous series from lowest to highest forms. This was considered to be the only way to make a natural classification and marks the passing of any serious efforts to create a philosophically based natural system.

Johann Wagler (1800-1832), based at the recently established museum in Munich, followed the developments and influence of Illiger. After studying various European collections, he began work on preparing the first detailed summary of all known birds since Latham, but only the first part of his proposed *Systema Avium* appeared in 1827, providing monographic coverage of 49 genera. This work was also an attempt to refine the nomenclature of birds. In 1830 he included a summary classification of birds in his *Natürliches System der Amphibien mit vorangehender Classification der Säugethiere und Vögel*, but his early death from the effects of a stray shot on a hunting trip curtailed further work on his ideas. René Primevère Lesson (1794-1849) had participated in the voyage of the *Coquille* around the world (1822-1825) and reported on the birds. His interest in ornithology led to the publication in 1828 of his little *Manuel d'ornithologie*, and the appearance of this work may have caused Wagler to discontinue his *Systema* project. Lesson later extended his classification with his *Traité d'ornithologie* (1830-1831) and published other systematic reviews, most comprehensively on hummingbirds, and also updates of Buffon's works. These classifications, like many of this period, had little or no lasting value and such works are mostly known today for the many genera and species named within these attempts to achieve a natural system.

Constantin Wilhelm Lambert Gloger (1803-1863) applied anatomical details to his partial classification in his uncompleted book *Vollständiges Handbuch der Naturgeschichte der Vögel Europa's* (1834). This study is notable for dividing the passerine order on the basis of the syrinx (i.e. clearly demonstrating the need to separate the old Pico-Passerines into passerines and picarian birds). Gloger began further studies on classification in *Gemeinnütziges Hand- und Hilfsbuch der Naturgeschichte* (1841-1842) but this work ended after one volume and is best known for various new genera proposed. Edward Blyth (1810-1873) wrote a series of six articles on the classification of several groups of birds in 1838. Blyth covered the passerines, and his results were notable for his attempts to use anatomical characters in some detail and apply the influences of geographical distribution. Blyth took his enlightened ideas to India, where he spent 21 years (1841-1862) as Curator at the Asiatic Society of Bengal Museum in Calcutta, producing a long series of papers, forming a solid foundation for Indian ornithology (Grote 1875). William Macgillivray (1796-1852) applied sev-

eral anatomical characters in his classification attempt in his famous *The History of British Birds* (1837-1852), considered the best work of its kind during that period (Mullens 1909c). He also contributed important details to the *Ornithological Biography*, vols 4-5 (1838-1839), of John James Laforest Audubon (1785-1851), wherein amongst other things he noted the distinctness of the tyrant-flycatchers (Tyrannidae) due to their syrinx, but he did not realize the implications. This work formed the text to the famous plates of *The Birds of America* (1827-1838), with Macgillivray's contributions replacing those of Swainson, who had fallen out with Audubon (Ford 1964).

Graf Alexander Friedrich Michael Lebrecht Nikolaus Arthur von Keyserling (1815-1891) and Johann Heinrich Blasius (1809-1870) looked at the syrinx and tarsal scutellation of some passerines in 1839. Their paper, *Über ein zoologisches Kennzeichnen der Ordnung der Sperlingsartigen – oder Singvögel*, described consistent patterns suggesting that these potentially useful characters needed further investigation. These studies were preliminary to their book *Die Wirbelthiere Europa's*, but only one volume was published, in 1840. Johannes Peter Müller (1801-1858) provided the results of his detailed study of the structure of the syrinx in his *Über die bisher unbekannten typischen Verschiedenheiten der Stimmorgane der Passerinen* (1847, translated into English 1878). He established the major division of passerines into the oscines and suboscines, and this conclusion has survived to this day as the first important study of the modern classification of passerines. Jean Louis Cabanis (1816-1906) was the curator at the museum in Berlin (1849-1892) and founding editor of the oldest ornithological journal still running, the *Journal für Ornithologie*; he was editor from 1853 to 1892, and as such had great influence in Germany. He was stimulated by Müller's work and applied the latter's findings to his study using external characters, such as the tarsal scutellation and number of primaries, in his influential interpretation of passerines in an essay known simply as *Ornithologische Notizen* (1847). These ideas were expanded in detailed family summaries presented in his catalogue *Museum Heineanum* (1850-1863), also a source of criticism of nomenclature and an attempt to eliminate barbarisms.

George Robert Gray (1808-1872) produced *A List of the Genera of Birds* in 1840, revised in 1841, updated in 1842, greatly expanded into three large volumes as *The Genera of Birds* (1844-1849), and summarized in 1855. All of these works were important in the fixing of type species to genera and had a great influence. Gray's three-volume effort was a standard work in its day. Alfred Newton (1896) praised it as a work of genius, although acknowledging Gray as "a thoroughly conscientious clerk" and only an ornithologist by accident. The work not only listed about 2400 genera and had many illustrations, but also provided lists of species for each genus. In spite of the increase in the number of genera and species by the 1840s, the basic Linnaean system still had to be made to accommodate them, especially after the Quinarians were discredited. When Gray later summarized every known name given to genera and species up to that time in his famous *Handlist* (1869-1871), he provided a wealth of detail in what became an important new classification. For an accidental ornithologist, Gray's contributions are all the more remarkable as being the cornerstone of all subsequent work on classification, as well as nomenclature.

Hermann Schlegel (1804-1884), Temminck's patient and long-suffering assistant and eventual successor, made an important contribution to the classifying activity in Europe in 1844. In both his *Kritische Übersicht der europäischen Vögel* and the first part of the *Aves* portion of *Fauna Japonica* he developed the first attempt at consistent use of trinomial nomenclature. He intended these names to be used to understand local variation of species in the way subspecific names are used today. This was also perhaps a more practical interpretation of the variety category in the Linnaean sense, which was applied in different ways by earlier workers. While Schlegel's ideas gained some followers, particularly in Germany (Haffer 1992), it would take another 50 years before this idea began to have serious influence on bird systematics. In 1844 there were still many problems interpreting classifications as fixed entities, although the implications of variation, in a more scientific sense, beginning with studying species, continued to intrude.

Charles Lucien Jules Laurent Bonaparte (1803-1857) began his studies in Europe under the influence of Temminck's *Manuel*. His work later developed with American birds, after his family was forced into exile and moved to Philadelphia, and he supplemented the pioneering work of Alexander Wilson's (1766-1813) *The American Ornithology* of 1808-1814 (Cantwell 1961). Bonaparte's interest in the classification of birds began in 1831 in association with an interest in all vertebrates. Plans at the time to collaborate with Swainson in a review of all known birds fell through because Swainson demanded too much money in order to be involved. His ornithological interests were combined with political activities in the 1840s, and eventually he planned to proceed with his review of all the birds of the world. Political events decided the

outcome, and in exile in the Netherlands from his family in Italy in 1849 he began his project with the support of Temminck and Schlegel at the museum in Leiden. This was to be his *Conspectus Generum Avium*, the first volume appearing in 1850 after intensive efforts. His punishing schedule was spurred on by assassination attempts on his family in Italy and fears for his own safety, and his work was completed shortly afterwards, in Paris, when he was finally allowed to return to France. The first volume included passerines but with a conservative classification, as Bonaparte's focus was on delineating genera and species.

This work marks the end of the first wave as it became the standard reference in its day for a summary of world birds, especially with its clear format and brief diagnoses of species. However, it needed a second volume to complete the coverage of all birds, and Bonaparte continued his work on it in Paris, as before also visiting other collections. He also later published an extensive series of papers, featuring the development of his higher classification of birds. He placed his families in parallel series, including tabulations of nearly all groups as he worked through them, creating many new families as well as genera and species in the process (e.g. Bonaparte 1853, 1854). His intensive activity continued through the 1850s as he worked with a sense of urgency due to his deteriorating health. He told a visiting friend, "The more I have to put up with, the more I work", when found writing in his bathtub (Hartlaub 1858). Although he distributed portions of the second volume of his *Conspectus* from 1854 almost up to his death in 1857, it was incomplete (Stroud 2000). Coues later commented: "I regard Bonaparte's services to the science of Ornithology to have ceased in 1850", and that all his later classifications were "not only a worthless but a pernicious aggregate", before launching into an attack on the eccentricities of his nomenclature, using hummingbirds as an example (1880). In some respects, Bonaparte's naming methods, so distasteful to Coues, were similar to the German school of classical purity criticized earlier by Hume. However, Bonaparte often applied his sense of humour to his naming and certainly did not appear to seek purity in his choices. In his last years Bonaparte also intuitively revealed an evolutionary interpretation of birds, as by then he was one of the few ornithologists familiar with world birds, and he had developed these ideas from this detailed familiarity.

Other developments after 1850 were influences or extensions of classifications established before 1850, such as the review of North America birds by Baird *et al.* (1858). Charles Darwin (1809-1882) finally brought out his *On the Origin of Species* in 1859 and the influence of this work in ornithology was soon apparent (e.g. Tristram 1859). Evolutionary ideas had been around for some time in one guise or another but it was Darwin who pulled it all together and crystallized the concept in a way that enabled it to be applied to systematic studies as never before (Mayr 1991; Gould 2002). The application of the theory of natural selection would soon begin to be applied to the classification of birds. Then, all the old philosophies and misguided ideas would be jettisoned, and Alfred Russel Wallace (1823-1913), an important influence on Darwin, hoped "that the chaos which has so long existed in ornithology will soon give way to a truly natural system which must obtain general acceptance" (1864). Blyth considered such chaos "as unmitigated heresy, to be repudiated by every devout ornithologist" (1866). But amongst the earlier works on bird classification there were still many good ideas and developments that would need to be reworked just to show that, while evolutionary studies would eclipse what went before, there had already been a number of ornithologists with insight and genius to pave the way.

### ***The second wave: evolution and adaptation (1867-1934)***

While there was resistance in some quarters to the impact of Darwin's book and its effect on how classifications had been worked out, it was also seen as a way, at last, to make serious progress in the quest to find the natural classification of birds. The second wave of activity in bird systematics was thus launched with a real sense of purpose and the differences between homology (affinity) and analogy took on completely new meanings. Thomas Henry Huxley (1825-1895), "Darwin's Bulldog", presented the first re-interpretation of birds in this new evolutionary light. In his paper *On the classification of birds* (1867) he devised his arrangement of the higher categories using the structure of the bony palate – "the great palatal subdivision". Huxley was soon criticized for applying only one character to his study (Newton 1868), and, while the choice of the palate seemed arbitrary, he was limited by the available material, where skulls were commoner than whole skeletons. This classification was very influential on subsequent developments in the investigation of anatomical characters and their potential taxonomic value. Although based on earlier principles, Huxley later used his classification as evidence of evolution (di Gregorio 1984). It was still to require a few more

years of investigation before the intimate relationship of the form of a character and its function was understood sufficiently when assessing its value in classifying birds.

Carl Jacob Sundevall (1801-1875) was based at the Natural History Museum in Stockholm for 32 years (1839-1871). He was long interested in the classification of birds and, as well as reports on collections, notably those of Swedish explorers in Africa, he wrote critiques on several earlier works, such as that noted above of Levaillant. He brought together all of his accumulated ideas on classification in his *Methodi naturalis avium dispondarum tentamen* (1872-1873, translated into English 1889). However, he considered it a mere new edition of his 1836 classification, so that in many ways it was already out of date. He used internal and external characters in creating his classification and considered both types to be of equal value. In spite of his old bias towards external characters he made extensive use of characters of the muscles of birds. His separation of most passerines was based on the absence of a vinculum between the deep flexor tendons of the toes. In spite of the flaws in his classification, the timing of its appearance gave it far more influence than it apparently deserved.

Philip Lutley Sclater (1829-1913) was closely following these new developments. During his 43 years as Secretary of the Zoological Society of London (1859-1903) he was at the centre of ornithological activity in England and encouraged many people to collect birds for the society, often writing the reports of discoveries himself. He was possibly the most prolific ornithologist of his day with the majority of his 1287 titles by 1896 on birds (Goode 1896), and he was editor or co-editor of the famous ornithological journal *Ibis* for all but a few years from its beginning in 1859 until 1912. He initiated a new series of anatomical studies in 1872 and, when reviewing progress in 1880, he also proposed his own classification, although he had already experimented with one earlier for his area of special interest, the Neotropics (Sclater & Salvin 1873). With the encouragement of Huxley, who wanted an anatomist working at the society, Sclater had already created the position of Prosector (a title made up by Huxley) in 1865 (Evans 1913). A succession of four anatomists, Murie, Garrod, Forbes and Beddard, held the post and published a large number of studies on birds over the next 50 years. Although this core of material had an impact on later developments in bird systematics, the classifications used during the period were still carrying much baggage from those of the previous century, partly thanks to Sundevall. Also, the last part of the most complete list of the birds of the world at the time had recently been completed (Gray 1869-1871). It bore the legacy of the beak-foot-feather school of systematics, yet evidence of Gray's characterizations of families can be seen in classifications ever since.

Alfred Henry Garrod (1846-1879) studied several characters, including the nasal bones, the carotid arteries, the tracheal and syringeal structures and the deep plantar tendons (Forbes 1881). His study of the muscles of the thigh, particularly the ambiens muscle, led to the development of his influential "pelvic muscle formula" for defining the higher categories of birds, and he presented his ideas in his paper *On certain muscles of birds and their value in classification* (1874). Like Huxley, his failure to understand fully the relationship of form and function created anomalies. His assistant and successor, William Alexander Forbes (1855-1883), reviewed Garrod's findings and studied additional characters and taxa, particularly in a series of papers on passerines (Beddard 1885). The tragic early deaths of Garrod, from a lung condition, and Forbes, from dysentery during a visit to Nigeria, prevented further development of the potential in ideas that both had demonstrated.

Elliott Coues (1842-1899) was one of the great figures in nineteenth-century American ornithology. He was a prolific writer and observer, producing some of the classic works of American ornithology, including a famous bibliography series, but he also wrote in many other areas and became embroiled in various controversies of the time, from sparrows to spiritualism. He later edited historical accounts of early exploration, but his incessant activity caught up with him and he succumbed to various illnesses on Christmas Day 1899 (Cutright & Brodhead 1981). His interest in classification came early, with his first important systematic publications appearing when he was only 19. He began to reconcile the old classifications with recent developments as early as 1872, in the first edition of his influential *Key to North American Birds*. As in England, the position of the passerines in the overall sequence (whether placed first or last), was an issue, and the preferred option varied amongst the classifications proposed. In 1872, Coues placed the passerines last but he changed them to first in 1874, in *Birds of the Northwest*, and there they stayed up to the first edition of the AOU Checklist (1886). In England, Sclater preferred passerines first, even after Coues visited England in 1884 to promote his views. This led to the situation where the second edition of the BOU Checklist (1915) was still "passerines first", in spite of the recent appearance of a British list adopting the new classification principles, with passerines last (Hartert *et al.* 1912). Ernst Hartert also used this book to promote the acceptance

of trinomial nomenclature in Britain. The influence of what Coues and others had been doing for the AOU had taken root in the Old World, but was still resisted in some quarters (Barrow 1998).

Richard Bowdler Sharpe (1847-1909) was the most famous ornithologist at the turn of the twentieth century. Much of this fame rested on the monumental *Catalogue of Birds in the British Museum* in 27 volumes (1874-1899). Although the task of its preparation was too much for one man, Sharpe managed to write about half of it and edited the remainder. In planning the work in 1872, Sundevall's classification was influential and formed a basis for the classification adopted, although parts were modified as it progressed, particularly from the anatomical work of Garrod and others. Also, Gray's *Handlist* of 1869-1871 was of obvious importance in resolving the fate of masses of names in need of coverage by the *Catalogue* classifications, although not all of them actually found their way into these volumes. In the *Catalogue* the birds of prey and owls came ahead of the passerines (Vols 3-15, 1877-1890). Sharpe's fame also rested on the many papers and books he wrote, particularly in later years with ten growing daughters to support, when he most famously completed the last of Gould's great folios (Fagan 1910; Ogilvie-Grant 1910). Moreover, he was possessed of a great sense of humour, and was friendly and supportive to everyone who came his way, so his sudden death on Christmas Day 1909, after a short illness, was a great shock at the time. But there was one person he did not get along with: Henry Eeles Dresser (1838-1915), a former collaborator of his, who wrote a major work on European birds. He was even known to try and lock Dresser in the museum overnight (Ingram 1966).

Anton Reichenow (1847-1941), son-in-law and successor to Cabanis at the museum in Berlin, developed his "logical" system as early as 1882, in his *Vögel der Zoologischen Garten*. He was, and remained, under the influence of the strong opposition in Germany to Darwinian ideas (Haffer 2001). His arbitrary system reflected the remnants of German nature philosophy with its roots in the sixteenth century. Reichenow became the leading authority on African birds in his day, describing many new species, as well as writing several important reference works. William Robert Ogilvie-Grant (1863-1924), Sharpe's assistant and later successor at the British Museum, complained about Reichenow's taxonomy. When discussing a particular species he opined that "this is only one of the many instances in which this author has relegated very distinct forms, which he has never examined, to the synonymy of some allied species" (1907). This may be a result of Reichenow's philosophy, but it has also been noted that "he dislikes the English and takes no pains to conceal it" (Meinertzhagen 1959). Opposition in France lingered, too, so that Léon Olphe-Galliard (1825-1893) did not see any need to change his 1857 classification in his major work, *Contributions à la faune ornithologique de l'Europe occidentale* (1884-1891). Nevertheless, as in England, the influence of the old guard was nearing an end.

Leonhard Hess Stejneger (1851-1943), a Norwegian, was advised to pursue his interests in birds in America, and he became associated with the Smithsonian Institution for 58 years, later working more extensively in herpetology. He was invited to contribute on birds to a popular work, and used the bird volume of *The Standard Natural History* (1885) to develop a detailed classification with much attention to anatomical, as well as external, characters, and in which he placed the passerines last. Stejneger provided detailed diagnoses of the higher categories and revised their nomenclature, bringing it close to current terminology, such as in the subdivisions of the passerines. The initial influence of this work was limited in Europe, as it appeared in a popular American work, but its favourable press brought it to the attention of Sharpe and Gadow, who were then reviewing and developing new classifications of birds.

Maximilian Fürbringer (1846-1920) was a comparative anatomist with an interest in birds. Working in the Netherlands, he investigated the evidence of previous classifications and, with a clear eye on the interrelationships of form and function, he produced two large volumes of 1750 pages under the title of *Untersuchungen zur Morphologie und Systematik der Vögel*, in 1888 (reviewed by Gadow, 1888). His study covered living and fossil birds and also attempted to trace the evolutionary origins of the Class Aves. His refinement of the higher categories of birds was well in advance of anything that had gone before, and he recognized 45 orders (his "Gentes"). Amongst other classification reforms, he abolished the traditional division of birds based on the absence (Ratites) or presence (Carinates) of a keel on the sternum (introduced by Merrem in 1816). The splitting of the ratites into several orders has been a feature of a large number of classifications ever since. At the other extreme, the passerines, placed near the end of his sequence, were considered to be so morphologically uniform that he placed them all in only two families.

Henry Seebohm (1832-1895) worked in the steel business, but in later years was able to devote more time to ornithology, with expeditions to Asia Minor and Russia to study birds also found in Europe in the field. He wrote books on British and Japanese

birds, shorebirds and thrushes, and through these he developed an interest in the higher classification of birds which he first summarized in *Classification of Birds* (1890, updated 1895). He recognized 14 orders and 36 suborders, all provided with brief diagnoses. Although his classification scheme was criticized, it was largely accepted by Sharpe in his *A Review of Recent Attempts to Classify Birds* (1891), an address to the Second International Ornithological Congress in Budapest. Sharpe's classification, with diagnoses of categories and placing the passerines last, was based mainly on Seebohm and Stejneger. In presenting his views, he used the image of the ideal museum exhibition, where each display presented the next part of his classification. He sent a copy to Huxley, who replied: "I wish something like it had existed a quarter of a century ago when I was trying to find my way through the chaos of Ornithological Classification. It would have saved me a world of labour, which I am glad to find was not altogether in vain." (Fagan 1910). Sharpe retained his 1891 classification in his last great work, the five-volume *A Hand-list of the Genera and Species of Birds* (1899-1909) because, as he noted in the introduction to volume one: "I have seen no reason to modify the conclusions there recorded in any material degree." However, when he reached the passerines (Vols 3-5), a few modifications were in fact made.

Hans Friedrich Gadow (1855-1928), a close friend of Fürbringer sharing his background in anatomical studies, was working in England as the Curator of the Stricklandian Collection and as a lecturer in vertebrate morphology, at Cambridge University. He also shared an interest in the classification of birds and developed his own scheme, the two having also contributed to each other's ideas. Apart from this collaboration with ideas and data, Gadow also reviewed all previous classifications since Huxley. His conclusions differed from Fürbringer's in several respects and he felt the need to apologize for publishing yet another classification of birds, first in his paper *On the classification of birds* (1892), and then in more detail in the section on bird systematics in Bronn's *Klassen und Ordnungen des Thier-Reichs* (1893). No apology was necessary. In reviewing earlier work, particularly synthesizing the mass of detail provided by Fürbringer, the classification he presented is the true parent of all higher classifications in use ever since.

Alfred Newton (1829-1907) was a distinguished professor of Cambridge University and a leading figure in ornithological developments for over 50 years (Wollaston 1921). He was also a friend and colleague of Gadow, and wrote a masterful and erudite essay on the history of ornithology down to 1896 in the introduction to his famous *A Dictionary of Birds* (1893-1896), with anatomical contributions by Gadow. He concluded his introduction by providing a thorough review of developments up to Gadow. After finally discussing the problems with classifying the oscine passerines, he remarked: "A perusal of the foregoing can hardly fail to confirm the doubts already expressed...as to the validity of any Systematic Arrangement of Birds as yet put forth. Still the history of ornithology, as here sketched, gives hope of the ultimate attainment of the object sought by so many earnest students of the Science, though a long time may yet elapse before that end is reached."

Frank Evers Beddard (1858-1925) followed through with the earlier plans of Garrod and Forbes to provide a handbook on avian anatomy, even though the recent publications of Fürbringer and Gadow made him feel the need for such a work was no longer there. Beddard, however, undervalued the usefulness of his *The Structure and Classification of Birds* (1898). It is a valuable summary for English-speaking ornithologists and anatomists and its utility for details of anatomical characters remains today; for example, it was the basis for diagnoses of orders and families in Sibley & Ahlquist (1990). Beddard focused on form in his book and William Plane Pycraft (1868-1942), in his *The History of Birds* (1910) was a critic of this approach, arguing that "habits precede structure". Arthur Humble Evans (1855-1943), working in collaboration with Gadow and following his classification, had already provided a valuable companion work to Gadow and Beddard with his volume on *Birds* in *The Cambridge Natural History* series (1899).

The arrival of the twentieth century coincided with a decline in interest in the higher classification of birds. It seemed that a natural classification of birds had been achieved, in spite of the views of Newton, but a trickle of publications continued for a while to tidy up some of the details. When two major regional works began, they also shared the view that only a few details needed to be sorted out because the new focus was on the systematics of genera and species, and on the development of the recently arrived subspecies, accepted after much debate. In fact, both works ensured a secure place for trinomial nomenclature. Robert Ridgway (1850-1929) began his great work on *The Birds of North and Middle America* in 1901 with the passerines, not as a statement on classification sequence of orders, but because the smaller birds were more readily available to study in the overcrowded museum collections. Ernst Johann Otto Hartert (1859-1933) began his great work *Die Vögel der Paläarktischen Fauna*

in 1903. He also started with passerines, because “conditions of work and space (not scientific reasons!) induced me to start with the higher forms”. This made a notable contrast to Hartert’s focus on the latest developments at and below the level of genus, so that in effect, like Ridgway, Hartert’s higher classification became one of convenience so that he could focus on other matters. In view of this it is notable that in the fourth part of Volume 1 (1907), he proposed an enlarged Muscicapidae (including Sylviidae, Timaliidae and Turdidae) because he thought there were too many intermediate characters.

Waldron DeWitt Miller (1879-1929), an Associate Curator at the American Museum of Natural History, was interested in the higher categories of birds and studied taxonomic characters such as pterylography, the digestive tract, carotid arteries, thigh and shoulder musculature, plantar tendons and foot structure, amongst others. He was an obvious choice to join the committee for the preparation of the classification to be used for the proposed fourth edition of the AOU Checklist and was appointed to the project in 1924 in association with Frank Alexander Wetmore (1886-1978). They jointly published a classification of North American birds in 1926, but their collaboration ended when Miller tragically died from his injuries, when his motorbike collided with a bus during a field trip; he left much important work unpublished (Lanyon 1995). The checklist came out in 1931.

Alexander Wetmore began his career in Washington, DC, with what later became the National Biological Survey, in 1910, and moved to the Smithsonian Institution in 1920, where he remained, later becoming Secretary and continuing his research there after retirement. His extensive taxonomic and other work covered both living and fossil birds. Through these studies and his work on the AOU Checklist he continued with his interest in the subject of higher classification and extended his investigations to cover the birds of the world. He published his first attempt in 1930, with slight updates in 1934, and reprinted in 1940. Gadow’s classification was the starting point, particularly for the non-passerines. While Gadow recognized only seven families of suboscines, Wetmore listed 16. For the oscines Gadow came up with a list of 28 families based on several sources, but particularly Sharpe, and explained away his choices on the grounds that the fine points of the recognition of families in the oscines were poorly understood and biased towards European birds. This eclectic element found its way into Wetmore’s conservative choices, and his classification, with its slight changes in the later versions, became the standard in museum collections and books, particularly in North America.

James Lee Peters (1889-1952), Curator of Birds at the Museum of Comparative Zoology, Harvard University, for 20 years, began making a card catalogue of the birds of the world in 1923 (Bock 1990). This increasingly complex task led him to decide in the late 1920s that Sharpe’s *Hand-list*, the only currently available world list, was in need of updating. In the introduction to the first volume of his world checklist he noted that the rapid increase in ornithological knowledge supported the need for such a new work. A major contribution to this increase was obviously the great proliferation of new subspecies, now that trinomial nomenclature was widely accepted in spite of lingering opposition in some quarters (Robin 2001). A few authors were particularly active in this regard, such as Gregory Macalister Mathews (1876-1949), mostly writing on Australian birds (Serventy 1950), and Austin Roberts (1883-1948) in South Africa, who also worked on mammals (Brain 1998). However, like others active in various parts of the world at the time, they also produced important reference works, adding to Peters’s concern about updating Sharpe. The other problem with Sharpe’s list was that he remained a strict adherent of binomial nomenclature, although he is said to have remarked jokingly that “three names were too many to put on a specimen label”. As a result, Sharpe listed as species birds that had been named as subspecies, even if he agreed the taxa were not species as he understood them. Peters followed Wetmore’s 1930 classification for all non-passerines and the first part of the suboscine passerines in the seven volumes he completed of his *Check-List of Birds of the World* (1931-1951) before his death.

Erwin Stresemann (1889-1972), based in Berlin, was the most influential ornithologist in Europe in his day, both through his many publications and his editorship of major journals (Haffer 2000). He was invited to prepare the *Aves* volume of Küenthal and Krumbach’s *Handbuch der Zoologie*, which was published in eight instalments (1927-1934). This work was highly praised in its day, but not as widely used as it deserved to be (Haffer 1994). He based his classification on Fürbringer and Gadow but took a more conservative approach to deciding the rankings. Of the 20 orders of living birds recognised by Gadow, Stresemann recognised 48 (extended to 51 in 1959). Similarities and differences with Wetmore (1930) in the oscine passerines, for example, reveal Stresemann’s classification to be as eclectic as Wetmore’s. Thus, the higher classification of birds had merely become one of practicality with no real progress since the 1890s, and in the view of some workers, studies of higher categories of birds

had run their course. The emphasis of systematic ornithology in the early twentieth century was not only focussed on species but on the rise of trinomial nomenclature, with a need to reclassify genera and species. The 1930s and 1940s saw the beginnings of genetic studies and the “new systematics”, with an emphasis on speciation and the species concept (Haffer 1992; see also Eck 1998; Johnson *et al.* 1999). As a result, much was done to bring order to taxonomy at and below the level of genus. Also, through the 1930s and 1940s various anatomical studies were undertaken and, as was seen earlier in the century, some higher classification details were clarified.

### *The third wave: phylogeny and biochemistry (since 1951)*

Ernst Mayr, the most famous ornithologist at the beginning of the twenty-first century, and Dean Amadon, proposed a new classification of birds in 1951. This grew from the various reports on attempts to work towards a natural arrangement of the higher categories of birds developed progressively through various family and group revisions. The inspiration for these studies was the recent arrival from England in the early 1930s of the world-famous Rothschild Collection, and its incorporation into the general collection of the American Museum of Natural History, New York. However, although presenting a revised classification, they also sought to avoid unnecessary changes to the earlier classifications of Wetmore and Stresemann. In the passerines the most notable changes were the recognition of the enlarged Muscicapidae, as proposed by Hartert, and the rearrangement of the sequence of oscine families by putting the crows and crow-like birds last. Both Wetmore and Stresemann had placed the New World nine-primaried groups of finches and their allies last. Later in 1951, Wetmore revised his classification in view of the increasing number of anatomical and other studies. He retained the “finches last” sequence of oscines (see also Friedmann 1955). Mayr (1955) reviewed recent examinations of anatomical characters used to work out the relationships of some of the oscine families. He disagreed with some of the conclusions in this “newly awakened interest in bird anatomy and bird phylogeny” but, while demonstrating that oscine passerines were not as anatomically uniform as once believed, he also cautioned against how these findings could be interpreted.

Mayr’s focus on the classification of the passerines had increased in importance when his move from New York to Harvard University in 1953 meant that he became responsible for the continuation of the world checklist begun by Peters. As with the old British Museum *Catalogue*, the amount of work required was too much for one person, so a number of ornithologists contributed to the remaining volumes, the last published in 1987. At the Eleventh International Ornithological Congress in Basel, Switzerland, in 1954, a committee was formed with the purpose of achieving some sort of consensus on the contentious issue of the sequence of oscine families. A stated aim was for the benefit of editorial standardization. In developing a classification, the phylogeny of the families needed to be considered, even if it was compromised for uniformity. Mayr & Greenway (1956) published the results, with the sequence putting the crows last, as preferred by European ornithologists (Mayr 1975).

Proving that the classification and sequence of the oscine families remained a controversial issue at the time, support for the “finches last” sequence soon followed (Wetmore 1957; Amadon 1957; Delacour & Vaurie 1957). Mayr (1958) defended the “crows last” sequence and restated the argument that, while these alternative systems were stimulating, the issue remained that in journals and non-taxonomic works one would be searching for a particular family at the beginning, middle or end of the sequence of oscines. As a result the “crows last” arrangement was subsequently adopted for the Peters checklist volumes (Mayr & Greenway 1960; see Bock 1990). In his last world classification, Wetmore (1960) discussed such issues but kept the finches last.

Stresemann (1959) reviewed what he considered to be the unsolved problems of avian systematics. He commented on recent work both favourably and critically, particularly the recent attempts by René Verheyen to find a whole new classification of birds based on a numerical analysis of skeletal characters; like some earlier classifications, this method threw up anomalies and inconsistencies and offered little of lasting use. On the relationships of the higher categories of birds it seemed reasonable then for Stresemann to think that these were largely unknown, if not unknowable, as he assumed that all sources of information had been exhausted. In a review of bird classification, Robert Storer (1960) discussed such problems, too, and adopted an eclectic classification drawing from recent work and placing the finches last in the oscine sequence. Unlike Stresemann, Storer thought that there were still new fields offering evidence for the relationships of the higher categories, noting comparative behaviour and protein chemistry as two promising fields; he again reported on new developments in 1971.

Charles Sibley began working in 1957 at developing techniques for comparing avian proteins by electrophoresis as a way to understand the genetics of hybrid populations. He also found that the electrophoretic patterns based on comparing egg-white proteins offered promise for understanding the relationships of the higher categories of birds (Sibley 1960). With further developments and improvements in techniques he provided new evidence in two major reviews (Sibley 1970; Sibley & Ahlquist 1972). By 1973 the limitations of these techniques were apparent, and he moved to new developments in DNA hybridization methods (Sibley & Ahlquist 1990; see also Corbin & Brush 1999). Over the next two decades, while new classification details were proposed, as new studies on various groups were undertaken, DNA hybridization emerged as an important research tool for interpreting taxonomic relationships.

Willi Hennig, an entomologist, introduced a new classification system, phylogenetic systematics, in 1950, but only when he revised and published his work in English in 1966 did the potential of his ideas gain wide influence. The system was based on the branching of lineages, thus renamed cladistics (or cladism). Cladistic analysis of characters requires their separation into ancestral (plesiomorphic) and derived (apomorphic) characters. To determine branching points in the phylogeny, it is necessary to trace backwards the uniquely derived characters (synapomorphies). Cladistic classifications could be constructed exclusively on the basis of branching points, and the method proves to be useful for reconstructing phylogenies. Groups sharing the same synapomorphies are sister groups. The results of cladistic analyses can be represented diagrammatically by cladograms. These show series of dichotomies marking the successive splits of the phyletic lines (Wiley 1981). Hennig's system attracted a large number of followers, with many changes and refinements to the system as originally envisaged by him. Cladistic methods have also attracted critics over the years. The two other taxonomic methodologies widely used are traditional or evolutionary methodology, the basis of earlier classifications, and numerical phenetics, which has been most effectively applied to unravelling confusing groups of genera and species (Mayr 1982).

Hans Wolters was the first to apply a phylogenetic approach to a list of the world's birds (Wolters 1975-1980, 1983), and he provided a complex but valuable higher classification to accommodate them. It is also notable for the first extensive application of subgenera, an area that had been of special interest to Wolters and several of his colleagues in Germany over the previous 50 years in particular. Joel Cracraft (1981) also developed a phylogenetic classification of birds, but only as a cladistic analysis of the higher categories. While Cracraft's hierarchies of higher classification offer new interpretations, the overall sequence was still the traditional one of Wetmore, ending with finches last. There were anomalies in how some of the details were worked out (Olson 1982; Sibley & Ahlquist 1990) and some of the problems raised by Cracraft's cladistic analysis have been investigated in later studies (e.g. Raikow 1987). Cracraft has continued to develop his ideas towards a revised classification of birds (e.g. Cracraft & Feinstein 2000).

Walter Bock (1982) worked out a traditional, evolutionary classification, but specialized morphologies compromised the attempt at a phylogeny (Sibley & Ahlquist 1990). For the passerines, the crows and crow-like birds were placed last in the oscine sequence. Storrs Olson (1985) offered a different classification based on a review of fossil birds, dividing bird groups into "basal" and "higher" (including passerines) landbird assemblages and a waterbird assemblage. In devising this arrangement, the assumption was that birds originated on land, and the assemblages are sequenced by degrees of specialization. Karel Voous (1985) updated the classification used in the 1964 *Dictionary of Birds*, which was based on Peters (1931-1951) and Mayr & Greenway (1956), for the revised version of *A Dictionary of Birds*. While Voous maintained a conservative approach to the classification, his modifications meant that it was another eclectic classification.

After publishing numerous papers on the findings based on DNA-DNA hybridization techniques (e.g. Sibley & Ahlquist 1985), Sibley and his colleagues, particularly Jon Ahlquist, exhibited a large wall chart of their conclusions for a world classification of birds at the Nineteenth International Ornithological Congress in Ottawa, Canada, in 1986. This chart attracted much attention and was dubbed "The Tapestry". It was subsequently published (Sibley *et al.* 1988; see also Mayr 1989, Sibley 1989). Sibley's important role in developing new understandings of the higher classification of birds reached its climax in 1990. At the Twentieth International Ornithological Congress in Christchurch, New Zealand, in December 1990, he launched two hefty volumes totalling some 2000 pages, making a *fait accompli* of his work on DNA. In these pages, there were a review of classifications, the interpretation of his DNA data (Sibley & Ahlquist 1990), and a world list of birds based on it (Sibley & Monroe 1990, see also 1993). In a second printing of Sibley & Ahlquist (1990), Sibley (1995) reviewed the

immediate aftermath of the book. He noted: "I have estimated that at least 75 percent of our conclusions agree with traditional ideas... The studies cited above show that independent research has confirmed additional pieces of The Tapestry, in spite of criticisms about the technique and our methods of analysis." Whether one agrees with all or some of the findings or not (e.g. Harshman 1994), Sibley's works, mostly with Ahlquist, have been most significant stimuli to further investigations on the higher classification of birds. Genetic studies have proved to be the most fruitful, particularly when used in conjunction with other data, such as morphology, biogeography and the fossil record (e.g. Cracraft 2001; Feduccia 2003). The pace of research has continued to increase (reviewed in Mindell 1997) and the techniques applied have also been refined and diversified (e.g. Helbig & Seibold 1999; Lovette & Bermingham 2000, 2002; Cicero & Johnson 2001). There is now an increasing focus on nuclear DNA, which apparently offers more consistent results (e.g. Ericson *et al.* 2000, 2002b; Shapiro & Dumbacher 2001; Irestedt *et al.* 2001; Barker *et al.* 2002). However, while the development of techniques such as comparing the sequence data of mitochondrial DNA and nuclear DNA have demonstrated congruity in phylogenetic analyses, conflicting data also have been found (e.g. Johnson 2001; Irestedt *et al.* 2002).

One consequence of the arrival of the new classification has been its impact on regional works, such as checklists and field guides. While a traditional classification has been retained by some (e.g. in Europe, Beaman 1994, Svensson & Grant 1999; and in Africa, Dowsett & Forbes-Watson 1993, Stevenson & Fanshawe 2001), the new classification has also been adopted in its entirety (e.g. in Asia, Inskipp *et al.* 1996, Robson 2000). In other cases, new, eclectic classifications are emerging, notably with the passerines (e.g. in North America, AOU 1997, 1998; in South America, Clements & Shany 2001, Ridgely & Greenfield 2001; in Australia, Christidis & Boles 1994, Higgins *et al.* 2001). Mayr & Bock (1994) argued that the standard (i.e. traditional) classification in wide use should be followed. After discussing their views, they concluded: "It may be best to wait until many, widely accepted changes have accumulated and then to undertake a single major alteration of the standard avian classification and sequence at one time." As Sibley (1995) pointed out, his findings were being increasingly supported. In the nine years since Mayr & Bock defended tradition, i.e. stability, evidence of the wide acceptance of changes, either agreeing with or refuting Sibley & Ahlquist (1990), is certainly accumulating.

A sampling of recent findings within the passerines indicates that:

- the southern origins of Oscine passerines is supported, with the New Zealand Wrens (Acanthisittidae) representing an ancient relict forming a sister group to all other passerines (Ericson *et al.* 2002a; Barker *et al.* 2002);
- the monophyly of the two clades of New World suboscines is gaining clarification (Prum *et al.* 2000; Irestedt *et al.* 2001; Birdsley 2002), but with recent evidence demonstrating that two genera traditionally placed in Rhinocryptidae probably represent a separate family of uncertain relationships, the newly proposed Melanopareidae (Irestedt *et al.* 2002);
- the lyrebirds (and probably scrub-birds) are the most basal group of the Oscines (Ericson *et al.* 2002b);
- the Corvida of Sibley & Ahlquist (1990) is not monophyletic, but their Passerida is (Ericson *et al.* 2002a; Barker *et al.* 2002);
- Madagascan taxa traditionally assigned to Pycnonotidae, Timaliidae and Sylviidae represent another ancient radiation comparable to the Vangidae, which also includes *Newtonia* (Fjeldså *et al.* 1999; Cibois *et al.* 1999, 2001; Yamagishi *et al.* 2001);
- various New World nine-primaried Oscine taxa traditionally considered as finches prove to be tanagers and *vice versa* (Burns 1997; Seutin & Bermingham 1997; Groth 1998; Klicka *et al.* 2000; Loughheed *et al.* 2000; Garcia-Moreno *et al.* 2001; Sato *et al.* 2001; Yuri & Mindell 2002), while the Old World genus *Emberiza* is not a recent offshoot (Grapputo *et al.* 2001);
- similar outcomes have been found with taxa traditionally considered thrushes or flycatchers, but in some cases their relationships apparently lie elsewhere (Pasquet *et al.* 1999, 2002; see also Sorensen & Payne 2001); and
- taxa traditionally placed in Paridae, Aegithalidae and Sylviidae are closely related (Sturmbauer *et al.* 1998).

It is now 13 years since the Sibley & Ahlquist classification stirred and stimulated a rapidly increasing field of investigations on the phylogeny of birds. The search for a natural system is alive and well.

### *Summary: all of the above and more to come*

This survey has been generally chronological and of necessity brief, and some well-known names have been omitted for this reason. The objective has been to demonstrate the multi-faceted nature of how naturalists, philosophers, anatomists and ornithologists have used their studies of birds to find how they can be grouped and classified in the quest to find a “natural system” or, more correctly, a classificatory system. The quest to broaden our understanding of the evolution and diversification of birds around the world continues. The limitations of space have principally confined this survey to passerines: their general similarity has made their classification seem deceptively simple but there can be some devil in the detail. We started out with a broad canvas, eventually leading to a tapestry, now being rewoven. Just when we think we know what the relationships of various families or groups appear to be, something new comes to light. However, while various problems appear clearly to have been resolved, others continue to reveal surprises.

### *Acknowledgements*

This brief history is dedicated to Alfred Newton and Erwin Stresemann. No history of birds can be written without Newton's famous introduction to his Dictionary (1896) and Stresemann's superb history of the development of ornithology up to 1950 (1951, translated into English 1975). For systematic ornithology the detailed historical reviews of Charles Sibley and Jon Ahlquist are invaluable. My debt to these ornithologists is apparent in this survey. My personal interest in ornithological history has a long history and I am grateful to many people who have helped me in various ways over 35 years. For this particular survey I thank Walter Boles, Per Ericson, Ian McAllan and especially Norbert Bahr for assistance with catching up on some of the recent publications. For comments on this foreword in its early stages I thank Per Ericson, Jürgen Haffer and Norbert Bahr. For assistance in various ways over the years and relevant here I also wish to thank Walter Bock, Siegfried Eck, the late John Farrand, Mary LeCroy, Gerlof Mees, Storrs Olson, the late Charles Sibley, Carlo Violani, Michael Walters and the late Hans Wolters. I here make an overdue thank you to Jon Ahlquist for showing me some of the early results of DNA-DNA hybridization during a visit to Yale University in 1976. For assistance with research on earlier literature I thank a succession of staff members of the Australian Museum Library, Sydney, and the National Library of Australia, Canberra, particularly the Petherick Reading Room. Over the years I also received much useful assistance with my historical research during visits to a number of museums in Europe and North America. I particularly want to mention the American Museum of Natural History, New York; the National Museum of Natural History, Washington DC; the Museum of Zoology, University of Michigan, Ann Arbor; the Museum of Comparative Zoology, Harvard University, Cambridge; the Bird Group, Dept of Zoology, the Natural History Museum (formerly Sub-Department of Ornithology, British Museum (Natural History)), Tring; and the National Museum of Natural History (formerly Rijksmuseum van Natuurlijke Historie), Leiden.

## *Introduction to Volume 8*

The beginning of the passerine volumes seems to us the ideal moment to incorporate a number of improvements in response to requests from readers and reviewers.

We are delighted to have been able to count on the concentrated efforts of several expert photographers who have been taking photographs specifically for HBW. The array of remarkable photographs in Volume 8, for relatively poorly known families, is testament to the expertise of these photographers, and we hope very much to be able to continue and expand this system for future volumes, in order to be able to provide representative selections of photos for all bird families.

Several reviewers have been urging us to adopt a clearer system of highlighting the accepted English name of photographed birds in the captions, so that the name can be picked out more quickly and more easily. We appreciate that for some readers this may have caused a certain amount of difficulty, so starting with the present volume, we have adopted a slight but important modification. In fact, the English name of the depicted species has always been included in each caption, but now the name is highlighted in bold. We believe that this will make identification much easier and simpler, especially for those readers who are not particularly familiar with the scientific names. Note that when two or more photos appear in a collage with a single caption, the species are always mentioned in logical order, e.g. top to bottom, or left to right; also, the highlighted names always appear in the text of the caption in the same sequence as the scientific names in the credits at the foot of the caption. A further improvement in response to the pleas of reviewers is the incorporation of the photo references into the Index. Thus, all photos are now listed by page number in the Index, using italics. Each photo is cited under the species' scientific and accepted English names.

In order to make the distributions depicted on the maps somewhat clearer and more precise, major rivers have now been added in to the base maps. It is hoped that these should be particularly useful in the interiors of large continental landmasses, where there is no coastline to act as a guideline.

Again in response to requests, in the References of Scientific Descriptions at the back of the book, each taxon is named alongside the page number of the publication in which it was first described. Thus, the exact page number for each taxon is quite clear.

Volume 8 exceeds all previous volumes in terms of the amount of previously unpublished information included. Part of the reason for this is the fact that most of the families and species covered in this volume are exclusively Neotropical. Until recently, the South American avifauna was very poorly known, but the amount of new and important information to have emerged in recent times is probably far in excess of the equivalent for other regions. A reflection of this is the very high proportion of new species discovered (rather than split) in the last 25 years that hail from this continent. All new information of significance incorporated into the HBW texts is, as ever, referenced in the Bibliographies as "unpublished notes", "M S" or the like. Also, because there is no comprehensive compendium on the biology of Neotropical birds to date, it has been reckoned appropriate to permit the inclusion of more detail in the species

accounts than has previously appeared for other, generally better documented families. Having stressed the significance of this volume for the Neotropical families involved, we would also like to commend to the reader the equally excellent work produced by the authors of the three Old World families in the volume!

There are a few brief observations to be made on the texts of some of the individual families in this volume, mostly on behalf of the authors in question. The authors of *Thamnophilidae* wish to stress that, in the species accounts of that family, listed lengths for each species are taken from unstretched museum specimens. For weights, they cited a range that excludes obvious extremes; the principal source of unpublished weights is the collection of the Louisiana State University Museum of Natural Science. Also, in the Food and Feeding sections of this family, they have incorporated large amounts of unpublished data, some of it quantified, some of it not, relating mainly to foraging behaviour, micro-habitats and nest descriptions. Many of these data are their own, but they also obtained unpublished information from a number of skilled, careful field ornithologists. The result is that many entries that would otherwise have read "Nothing known" are now filled with extensive, often highly detailed, descriptive information as well as previously unpublished quantified data. In an attempt to make clear which sections are drawing heavily upon unpublished sources, the section opens with a statement such as "Little published" or "Nothing published". Contributors of unpublished data are flagged by a "2003" entry in the bibliography of species accounts that can be cross-referenced to an entry in the General List of References under a entry such as: "Notes on thamnophilid antbirds". The author of *Furnariidae* considered that for this family it would be particularly useful to include the "official" habitat categories of each species as designated by Stotz *et al.* (1996). To this end, the Habitat sections of the species accounts in this family open with these designated categories, before proceeding to more specific remarks about the species in question.

As ever, the page immediately before the initial page of the first family in an order is given over to a summarizing "order page". Given the huge number of families involved in *Passeriformes*, readers will not be surprised to see a slightly modified format for this order. This modified style has been designed with the intention of keeping everything as clear and uncluttered as possible, while retaining all the families on a single page, and without straying too far from the lay-out of order pages in previous volumes. On the order page, the families covered in the current volume are highlighted. The intention is to repeat this order page at the beginning of each new volume, with the relevant block of families highlighted. As publication of the final volume in the series is still some years away, the editors would like to stress that a few minor modifications may yet be made to this sequence as the series progresses. However, it is confidently expected that any such changes will be few and far between.

At the petition of some authors, for the first time certain important sound recordings have been included in the reference list. This is a matter that needs a certain amount of control, mainly to avoid the inclusion of a mass of informal and not readily obtainable recordings, but it is hoped it will be possible to continue and perhaps extend this system, with great care, in forthcoming volumes.

One general point on HBW norms that we should like to stress to readers is that it is important to take the Distribution sections in conjunction with the Taxonomy sections. HBW distributions aim to be concise, so that the reader can see at a glance where a particular species or race occurs. This is, of course, particularly relevant for polytypic species: at the species level, a glance at the map immediately gives a general idea of the distribution, which can then be complemented by further details in the text, but to check subspecific distribution, the map must necessarily be taken in conjunction with the text. In order to avoid subspecific distributions becoming too long and involved, and difficult to interpret, relevant taxonomic details (e.g. intergradation, clines, etc.) are normally dealt with in the Taxonomy section, as there is more ample scope here for lucid explanation, without the details becoming entangled in the midst of the written distribution. For example, if we look at the case of *Philydor ruficaudatum* on page 335, we see in the Taxonomy section that there is a very complicated situation involving extensive intergradation of all three of the accepted races; that the perceived variation will probably prove to be clinal; that further study and analysis is required; and that the species is likely to end up being considered monotypic. To include all of these taxonomic details that are relevant to distribution in the midst of the Distribution would lead to long, involved, confusing statements, and a good deal of repetition, so in HBW such comments are normally restricted to the Taxonomy section.

For the present volume, we are delighted to be able to include a most interesting foreword on the history of bird classification by Murray Bruce. This essay provides a wealth of details behind the lives and work of some of the great figures in the history of ornithology, highlighting their most important contributions towards the development of ornithological research and thought.

With Volume 8, HBW starts its coverage of the Passeriformes. As this single order will occupy all the remaining volumes in the series, we think that a few introductory remarks may be appropriate, mainly concerning the general features of the order, a few selected details regarding the history of its treatment to put the HBW treatment into perspective, and finally a few brief notes on the internal division that has been adopted herein. Up to now, no order has spread from one volume of HBW to the next, with the result that most of the general features of each order are readily apparent from the texts, plates and photographs pertaining to each order, as well as being discussed to some degree in different families. It is worth noting that, in terms of number of families recognized, the largest order covered to date (by some considerable distance) has been the shorebird order, Charadriiformes, with 18 families. With nigh on 100 families planned for Passeriformes, it seems appropriate to provide a brief summary of some relevant features before embarking on this enormous block. For far more detailed coverage (and details of references) of the historical side, please see Murray Bruce's foreword.

Amongst the 30 or so orders normally recognized within the Class Aves, the passerines (Passeriformes) stand out as being the most advanced and by a long way the most diversified in terms of species richness. Whichever species concept is preferred (see Haffer, HBW 4, pp. 11-24), whichever individual classification is adopted, the passerines invariably comprise more than half the known species. Glancing at higher ranks, over during the last century or so, in most classifications, over half of all bird genera, and usually almost half of all bird families recognized, are passerine. It should be underlined that the business of both familial and generic limits are rather grey areas, ruled by decisions that tend to be somewhat subjective and often rather arbitrary, largely because these are purely human concepts, invented for ease of classification, and which presumably have no significance whatsoever to the birds themselves. For example, in highly simplified terms, we assume that a Eurasian Blackbird (*Turdus merula*) on seeing and hearing a Mistle Thrush (*Turdus viscivorus*), a Eurasian Robin (*Erithacus rubecula*) and a Common Wren (*Troglodytes troglodytes*) does not see the second of these three as being more closely related to it than the third and less closely than the first, but essentially sees all three as "non-Blackbirds". Returning to the diversity of the passerines, and in spite of the inevitable subjectivity, all the aforementioned statistics are clear evidence of the degree of perceived diversity within the order Passeriformes. In practical terms, one of the more obvious outcomes of this is that all taxa within the Class Aves are regularly referred to as either "non-passerine" or "passerine"; virtually any series of books or papers on birds that is divided into two or more parts is likely to have a split between parts coinciding with the switch from non-passerines to passerines.

The passerines are sometimes referred to as the "perching birds", and to this end their feet are well adapted to perching with four forward-pointing toes all on the same plane, with a backward-facing hallux in opposition. The other vernacular name for the group, more precisely referring to the oscines, is "songbirds", and again this is reflected in the highly distinctive morphology of the syrinx.

The passerines are found worldwide, in virtually all habitats except around the poles. Apart from a few wetland ecotypes and some oceanic islands, passerines tend to be the order represented by the largest number of species in the avifauna of almost any site in the world. They are frequently the commonest in terms of absolute numbers of individuals too. Compared with most non-passerines, the passerines are generally rather small-sized birds, with many fitting the "tiny" category, whereas the largest are some of the crows (Corvidae), only rather moderate-sized in the context of the non-passerines. The passerines include many of the "tamest", commonest and most easily observed species throughout the world, some of which are amongst the species best adapted to man-made environments; yet, the order also contains some of the most determined skulkers of all, species that are seen only very rarely, if ever, without the aid of tape-recording playback.

Despite the large number of species recognized, the passerines form a rather uniform assemblage, and it is quite some time since there was any serious dispute as to whether or not any particular taxon should or should not be placed within this order. Of course, the same can also be said about most other bird orders, and the vast majority of cases of disputed assignment to order concern disagreement essentially regarding ordinal limits: whether to lump or to split in particular cases — essentially the same difficulty already referred to above in connection with genera and families. For example, the extant taxa of ratites were commonly placed in four orders during much of the last century, but nowadays most authors prefer to lump them all into a single order, Struthioniformes, and indeed they are sometimes even merged with the tinamou order, Tinamiformes. Very few indeed are the cases of taxa being switched between two "independent" orders, amongst the most striking cases being: the Hoatzin (*Opisthocomus hoazin*), disputed between the Galliformes and the Cuculiformes, and in HBW awarded its own order, Opisthocomiformes; the sandgrouse (Pteroclididae), disputed between the Columbiformes and the Charadriiformes, and likewise in HBW awarded its own order;

and the Plains-wanderer (*Pedionomus torquatus*), traditionally placed amongst the Gruiformes, but now generally considered to belong in Charadriiformes, and treated thus in HBW. An example of the consolidated uniformity in treatment of the limits of Passeriformes can be found in Wolters (1982), who, although he recognized 50 orders and subdivided a large number of the traditionally accepted orders including Anseriformes, Falconiformes, Gruiformes, Charadriiformes, Coraciiformes, etc., nonetheless left the limits of the Passeriformes intact. Traditional views have considered the orders most closely related to Passeriformes to be Coliiformes, Coraciiformes and in particular Piciformes.

In the early stages of "modern" ornithology, under 350 years ago, there was no real sign of a passerine group emerging yet in attempts at classification. For example, W. Charleton (1668) had two main divisions of birds, namely the landbirds and the waterbirds. The former were further divided into seven categories, based on food, bathing and singing, but passerines and non-passerines were liberally mixed together through most of these categories, while the Dipper (*Cinclus*) was, not unreasonably, classified amongst the waterbird groups.

Within less than a century, however, the isolation of the passerines was beginning to take shape. In the sixth edition of his *Systema Naturae*, in 1748, Linnaeus recognized six orders of birds, the sixth, Passeres, consisting largely of modern-day passerines, though with the odd pigeon, hummingbird, etc., thrown in, while just a few other modern-day passerines were placed elsewhere, such as crows in his Picae.

Moving the clock on a century or so, G. R. Gray's influential works of the mid-nineteenth century recognized many of the modern-day families, as well as quite a number of what were to become "traditional" groupings, but his subdivision of his Passeres into four groups based primarily on bill-shape still bore little resemblance to modern classifications, and included members of many groups subsequently placed in other orders, including Opisthocomiformes, Cuculiformes, Caprimulgiformes, Apodiformes, Coliiformes, Trogoniformes, Coraciiformes and Galbuliformes, though admittedly these non-passerine intruders were generally quite well bunched together, rather than all mixed up in the midst of the "modern-day" passerines. Gray's classification, however, still maintained in close proximity several groups now considered unrelated, and only superficially similar due to their similar habits, notably: swallows and swifts; Old World flycatchers and tyrant-flycatchers; and sunbirds, honeycreepers, hummingbirds and honeyeaters.

Gray's list was perhaps the last really important one not to see the passerines united in their own order without any "foreign bodies" included. Important detailed studies had meanwhile been in progress, particularly in Germany, where C. L. Nitzsch (1840) analysed pterylosis in different groups; by 1829 Nitzsch had already come to the conclusion that the swifts actually belonged alongside the hummingbirds, with no close relation to the swallows at all. By 1834, C. W. L. Gloger, based on studies of the syrinx, established the unity of the passerines, calling for their separation from all of the non-passerines that had still been placed alongside them. Also of great significance at this time was the work of J. P. Müller, who likewise studied the structure of the syrinx, his results and conclusions being published in 1847 in German, with a translation into English in 1878. He established the major subdivision of the passerines into two clear groups, the suboscines and the oscines, based on the simpler syringeal morphology of the former. This division stands to this day, having been supported by a large number of subsequent studies, in more recent times including various biochemical analyses.

By the latter part of the century, and the second International Ornithological Congress in Budapest, in 1891, many advances had been made so that R. B. Sharpe's proposed sequence of passerines now bore a considerable resemblance to the classifications in vogue during most of the twentieth century, except that it was back-to-front, the families being listed from what was considered the most advanced to the most primitive. Over the following years Sharpe worked in conjunction with many of the most eminent ornithologists of his day to produce his *Hand-List of the Genera and Species of Birds*, the passerines appearing between 1901 and 1909 in Volumes 3-5. This work probably represented a reasonable compromise of the main views current at the time. In many details, this list was similar to his 1891 proposal, but the sequence was now more or less inverted. Its major features can be detected throughout all the classifications that dominated the ornithological world right up until the advent of the DNA classifications in the latter part of the twentieth century.

Over the following century or so, in traditional classifications treatment of the suboscines remained fairly conservative, but not so the oscines, in which three large, informal blocks of families were normally recognized: the Old World insect-eaters and relatives; the crows, birds-of-paradise, and associated families; and the New World insect-eaters and finches. The various systematists interchanged the positions of these groups in accordance with their views, but the groups themselves tended to remain largely intact. In different parts of the world, different sequences tended to gain pre-

ponderance, the Basel sequence with the crows last dominating in Europe, and the Wetmore sequence with the finches last leading the way in America (see Bruce, HBW 8, p. 32). Ultimately, the latter can be said to have triumphed among traditional classifications, and this is the sequence that forms the backbone of the HBW passerine list. Round the framework of these three major groups within the oscines, the other "unattached" families were variously positioned. The larks (Alaudidae) and swallows (Hirundinidae) formed two independent entities in themselves in having distinctive syringeal morphological features, and these two families have usually been placed at the beginning of the oscines. Additional loose groupings that can be detected in most twentieth-century classifications include the Old World nectar-eaters, the shrike group, and the tits and creepers.

The last part of the twentieth century has witnessed a huge upheaval in ideas, chiefly through the DNA-DNA-hybridization work of C. G. Sibley and J. E. Ahlquist. They proposed dividing the oscines into two major groups, Corvida and Passerida, and realigning many hitherto accepted relationships. How many of their conclusions will stand the test of time remains to be seen, but several of their findings have already received additional corroboration, and some have been adopted into classifications. Amongst the most important of their results would appear to be the significant position of Acanthisittidae at the base of all the passerines, representing the last survivors of an ancient lineage; and also the idea that several Australasian endemic families are much more closely related to each other than they are to the more northerly based families with which they have long been associated. Sibley and Ahlquist's work has stimulated a tremendous upsurge in interest in avian taxonomy in general, with genetic studies now being carried out on numerous groups all round the world. New results are being published with increasing frequency, and amongst the most exciting is the evidence of an ancient Madagascan lineage that is now also emerging. Certainly, it is true that different biochemical studies have produced contradictory results in several cases, but with increasing amounts of research being carried out, and refinements in techniques, it should prove possible work ever closer towards the "natural" classification that has so long been sought, and has at various times appeared quite unattainable.

As already stated, on the basis of syringeal morphology two well-marked groups can be seen within the passerines, namely the suboscines and the oscines. The suboscines generally have much less complex vocalizations than the oscines, and they show very unusual anatomy of the inner ear; the vast majority of species (some 1170 in about 12 families) are restricted to the Neotropical Region, with just some 50 species in three families occurring in the Old World tropics, mainly in South-east Asia. In contrast, the oscines are the typical songbirds, generally considered the most advanced of all birds, and characterized by their complex songs; they occur almost worldwide.

The suboscines have frequently been treated as a sole suborder, or even, on occasion, order (Tyranniformes), but such treatment appears to conceal some significant differences. The Old and New World groups have usually been recognized as not particularly closely related, but the pittas (Pittidae) were long left floating around in no man's land, until they have now been recognized as belonging relatively close to the broadbills (Eurylaimidae) and the asities (Philepittidae) in an Old World suboscine assemblage. Whether the New World taxa should be placed in a single suborder or in two remains controversial, but the current trend appears to be heading back towards two groups, Furnarii and Tyranni, with tracheal and tracheo-bronchial syringes respectively; this is the option adopted in HBW.

The suboscines provide a good example of one of the main problems besetting the classification of the passerines, namely where the limits should be drawn between the different families. Pittidae is the only member of the group which seems to have undisputed family limits. For the others, various authors would advocate treating: the asities as merely a subfamily of the broadbills; alternatively, the asities as forming two separate families, Philepittidae and Neodrepanidae; the woodcreepers (Dendrocolaptidae) as a subfamily of the ovenbirds (Furnariidae); the typical antbirds (Thamnophilidae) and the ground-antbirds (Formicariidae) as a single family, Formicariidae, with or without the gnateaters (Conopophagidae); the tapaculos (Rhinopectidae) as two families, with the erection of a family Melanopareidae; the cotingas (Cotingidae), manakins (Pipridae) and tyrant-flycatchers (Tyrannidae) as a single family; or, alternatively, their subdivision into more than the three families accepted in HBW, with the recognition of such families as Phytotomidae, Oxyruncidae, Rupicolidae, Tityridae, etc.

Although the difference between oscines and suboscines is clearly defined, there are two small Australasian groups that do not fit well into either section. To emphasize their distinctiveness they are sometimes awarded separate suborders, Acanthisittae and Menurae, as is the treatment in HBW. The first comprises only the New Zealand wrens (Acanthisittidae), a group now reduced to just three species, one of which is almost certainly extinct. This group shows unique features in its ear and muscle morphology,

as well as an unusual bronchial syrinx without intrinsic muscles. It has long proved a problem taxon to systematists searching for its closest relative, but very recently different workers (Ericson *et al.* 2002, Barker *et al.* 2003) have arrived at the same conclusion as Sibley and Ahlquist, namely that this family is a relict of primitive representatives of the passerines, and may be the sister taxon to the entire rest of the order. For this reason there are good arguments for isolating this family, and perhaps for placing it first within the passerines, though, with the ink is still wet on these conclusions, for the purposes of HBW it has seemed better to place this group tentatively between the suboscines and the oscines, near its traditional position where most readers would expect to find it, and in its own suborder to emphasize its probable significance in terms of the genealogical history of the whole order.

The second suborder intercalated between the suboscines and the oscines is Menurae, consisting of the lyrebirds (Menuridae) and the scrub-birds (Atrichornithidae), both exclusively Australian in distribution. Both have slightly less complex syrinx morphology than found in the oscines, for which reason their taxonomic placement has long hovered between the two major passerine groups, though it is now generally agreed that they belong alongside the oscines. K. H. Voous (1977) suggested that, on the basis of their syringeal morphology, the lyrebirds and scrub-birds were actually the "true suboscines", and he proposed the replacement name "deutero-oscines" for the groups traditionally known as "suboscines", but this proposal has never really caught on, and the name "suboscines" is still applied more or less universally to species herein placed in the suborders Eurylaimi, Furnarii and Tyranni.

It may be of interest to note with regard to these first five suborders that, apart from an extensive overlap between the questionably separable Furnarii and Tyranni and a marginal overlap between a few species of Eurylaimi (pittas) and Menurae, they are otherwise geographically exclusive. The suspected Gondwanan origin of the passerines certainly receives some support in the fact that these pre-oscine suborders have distributions almost entirely restricted to the lands of the ancient southern supercontinent. In accordance with this view, the oldest passerine fossils known to date are fragments found in Queensland, Australia, dating back to the early Eocene, some 50 million years ago, whereas the oldest known oscine remains come from France and date to the Upper Oligocene, some 30-25 million years ago. Nevertheless, the New Zealand wrens are now reckoned to have broken away from the main passerine lineage quite some considerable time earlier, about 85-82 million years ago, during the Cretaceous.

Whether the Passeriformes are subdivided into just two suborders or anything up to seven (Wolters, 1982), the number of taxa allotted to the oscines remains much the largest, comprising about 80% of the passerine species, and still very close to half of all bird species. The overall structural homogeneity of birds in this suborder has been one of the greatest stumbling blocks thwarting attempts to produce a "natural" classification, as the differences visible must often be put down to convergent evolution, with the result that very similar-looking species may not be particularly closely related, whereas other apparently rather diverse forms may be close relatives. The difficulty in establishing widely agreed family limits has consistently proved a major problem, and indeed in 1880 led P. L. Selater to observe that all oscines were so closely related as essentially to be equivalent to a single family in the context of other birds groups. Historically, the main argument against this has been one of practicality: a single family of some 4500-5000 species would be quite unmanageable as such, and would undoubtedly complicate various different forms of research in various different ways. Thus, we return to the eternal conflict of the search for the truly "natural" classification, the impossibility of depicting it in linear form, and the overall importance for the progress of research in having an operable working system (see Bock, HBW 2, pp. 13-15). Efforts have generally been combined towards a form of compromise, in producing a list as close to reflecting true relationships as deemed reasonably possible, but within a practical framework.

As already remarked, the definition of family rank and limits has proved particularly difficult within this order. Almost any of the main groups have been the object of much debate regarding the most appropriate family limits to be applied. Thus, for example, in the Basel sequence, following E. Hartert, the family Muscicapidae was considered to include not only all other Old World flycatcher families, such as Monarchidae, Rhipiduridae and Platysteiridae, but also the other three large families in the assemblage, Turdidae (thrushes), Timaliidae (babblers) and Sylviidae (warblers), as well as their various derivatives, or apparent derivatives, such as Picathartidae, Paradoxornithidae, Pomatostomidae, Orthonychidae, etc. Similarly, an outsized Emberizidae has at times been recognized, including several other families such as Thraupidae (tanagers), Vireonidae (vireos), Parulidae (New World warblers), etc. Such enormous families at times present severe practical complications to scientists, and may not be any closer to a true reflection of relationships anyway. HBW prefers to follow a narrow family concept, tending to emphasize the differences rather than the similarities.

## Acknowledgements

Once again, our first acknowledgement must be for the enormous help received from museums. Chief of these are the British Museum of Natural History at Tring (Robert Prys-Jones, Michael Walters, Mark Adams, Cyril Walker, Alison Harding), the American Museum of Natural History in New York (Joel Cracraft, George Barrowclough, Mary LeCroy, Paul Sweet, Shannon Kenney, Peter Capainolo, Terry Chesser, Maria Rios), the Louisiana State University Museum of Natural Science (Van Remsen, Steve Cardiff, Donna Dittmann, Mario Cohn-Haft, Dan Lane, Alexandre Aleixo, Jason Weckstein, Rob Faucett, John O'Neill) and the Smithsonian Institution, National Museum of Natural History in Washington (James Dean, Gary Graves, Pam Rasmussen, Richard Zusi). Also of great assistance were the Field Museum in Chicago (David Willard, Shannon Hackett), the Colección Phelps de Venezuela (Miguel Lentino, Margarita Martínez, Clemencia Rodner, Robin Restall), the Delaware Museum of Natural History (Gene Hess), the Museum of Comparative Zoology in Harvard (Alison Pirie, Peter Alden, Jeremiah Trimble), the National Museums of Scotland in Edinburgh (Bob McGowan), the Natuurhistorisch Museum at Leiden (René Dekker, Martien van Oijen), Liverpool Museum (Tony Parker), the Departamento de Zoologia Universidade São Paulo (Luis Fabio Silveira) and the Academy of Natural Sciences at Philadelphia (Nate Rice).

For help in many different ways with matters related to bibliography and references, we are immensely grateful to *Aves Argentinas* (Óscar A. Spitznagel, Cecilia F. Simonini, Alicia G. Cabo), the Biblioteca Instituto Biociências at the Universidade de São Paulo (Rita de Cássia Santos Ferreira, Maria José de J. Carvalho), the Bibliothèque Nationale de France, Dante Buzzetti (CEO), Ernesto C. Enkerlin, the Estación Biológica de Doñana (José Cabot), the Fundação Parque Zoológico de São Paulo (Rosana Alves Ferreira), Juan Carlos Guix, Miguel Lentino, the Library of the Academia Nacional de Ciencias de Córdoba in Argentina (Marisel Pereyra), Alberto Madroño, the Museum of Zoology of the University of Michigan (Janet Hinshaw), the Museum National d'Histoire Naturelle in Paris (Evelyne Bremond-Hoslet), the Museo Nacional de Historia Natural de Santiago de Chile (Luis Hidalgo López), the Natural History Museum in South Kensington (John Rose, Ann Datta), the Ornithological Society of Bavaria (Juliane Diller), Rainer Radtke, the Sociedad Española de Ornitología (Blas Molina), Mirco Solé and Doriane Zimmermann (Camargue).

We are especially grateful for help provided with the texts in various ways, particularly in refereeing final drafts and supplying information, much of it unpublished. We thank David Ascanio, Constantino Aucá, Murray Bruce, Nigel Collar, Bob Dowsett, Edson Endrigo, Gregorio Ferro, Luiz Gonzaga, Ingo Hahn, Cristina Edda Lúchau, Roberto Molina Viveros, Richard Noske, Storrs Olson, D. Rogers, Anita Studer, W. Suarez, Olivier Tostain, Barry Walker, Bret Whitney and Udo Zimmermann. As already mentioned above, many others have kindly provided a great deal of unpublished information directly to the authors, and the most significant contributions are referenced in the relevant bibliographies. Nonetheless, we would like to take this opportunity to thank them all very much for their much valued contributions to the project.

As in previous volumes, Robert Ridgely has very kindly revised all the maps affecting Neotropical species. The huge number of them in the current volume has presented him with a hefty workload, but, as ever, he has made his very useful corrections and suggestions both rapidly and clearly. We are extremely grateful to him for all his hard work.

For assistance in checking various details in connection with the scientific descriptions, as ever we owe a big debt to Alan Knox; special thanks too to Normand David, and also to Murray Bruce, Ann Datta, Janet Hinshaw, Miguel Lentino, Manuel Nores and John Rose. Once again, we are very happy to have been able to benefit from our agreement with VIREO at the Academy of Natural Sciences in Philadelphia (Doug Wechsler). Likewise, we are extremely grateful to Guy Tudor, who continues to put his fine collection of photos at the disposal of HBW.

The French and Spanish names come from the same sources as in previous volumes; our thanks to Normand David and Eduardo de Juana and their respective associates for dealing with any problems swiftly and efficiently. The accepted list of German names is still being extensively revised, but we have been fortunate to be supplied with the most up-to-date list currently available by Christoph Hinkelmann, who also dealt very ably with any questions. Our thanks, too, to Peter Barthel for putting us in contact with Christoph.

The various authors and artists would like to express their grateful thanks to the following: Herculano Alvarenga, José Álvarez, Mauricio Álvarez, Luiz dos Anjos, John Arvin, Adrian Azpiroz, Bas van Balen, Richard C. Banks, Pierre Bannon, John Bates, A. Begazo, Robert Behrstock, William Belton, A. van den Berg, Catherine R. Bevier,

Louis Bevier, Walter Boles, Chris Bowden, Jack Bradbury, Frederick Brammer, Michael J. Braun, Greg Budney, Dante Buzzetti, José Cabot, C. Daniel Cadena, Peter Capainolo, Steve Cardiff, J. Cartwright, Gloria Castiglioni, Douglas Causey, R. Terry Chesser, Santiago Claramunt, George Clark, Rob Clay, Mario Cohn-Haft, Paul Collins, Paul Coopmans, Andres M Cuervo, Normand David, L. I. Davis, Daniel Davison, James Dean, D. Delaney, Rafael A. Dias, E. C. Dickinson, Thomas Donegan, P. Donohue, R. J. Dowsett, F. Dowsett-Lemaire, Siegfried Eck, Uli Ehlert, Gunnar Engblom, Thorkild Erritzoe, Krista Fahy, Alan Feduccia, D. Finch, Annette Finney, Martha Fischer, Lincoln Fishpool, Jon Fjeldsâ, Rosendo Fraga, Juan Freile, Göran Frisk, Richard A. Fuller, Paul van Gasse, Jaqueline Goerck, Luiz Gonzaga, Gary Graves, Shannon Hackett, Frank Hawkins, Floyd Hayes, Sebastian Herzog, Steven Hilty, Mort Isler, Phyllis Isler, Álvaro Jaramillo, Ned K. Johnson, Francis Kahn, Shannon Kenney, Guy M. Kirwan, Niels Krabbe, Andrew Kratter, Donald E. Kroodsmas, Frank Lambert, Geoff LeBaron, José Lima de Figueiredo, Andres Link, Niels Linneberg, Bradley C. Livezey, Gustavo Londoño, L. Macaulay, Virginia Mackay, Sjoerd Maijer, Manuel Marín, Miguel A. Marini, Ben Marks, Peter Marra, Aline Y. O. Matsuo, Juan Mazar Barnett, Ian McAllan, Bob McGowan, Fernando Mendonça d'Horta, Eduardo T. Mezquida, Christopher Milensky, Jeremy Minns, John Moore, Luciana Nicolas Naka, Jonas Nilsson, Manuel Nores, Manuel Nores, Storrs Olson, John O'Neill, Yoshika Oniki, David C. Oren, Brian J. O'Shea, José Fernando Pacheco, Robin K. Panza, Ted Parker, Robert B. Payne, Martín de la Peña, Shaun Peters, Alan Peterson, Alison Pirie, Manuel A. Plenge, Fernando Puebla-Olivares, Richard Ranft, Pam Rasmussen, Van Remsen, Robin Restall, Rômulo Ribon, Nate Rice, Robert S. Ridgely, Luis Rivera, Mark Robbins, Clemencia Rodner, Osar van Rootselaar, Kenneth Rosenberg, D. L. Ross, Jr., R. A. Rowlett, A. Sada, Paul Salaman, Thomas Schulerberg, Marcus Schuster, P. Schwartz, Luís Fábio Silveira, F. Gary Stiles, Douglas Stotz, Jeffrey Stratford, Philip C. Stouffer, Fernando Straube, Bent Sunesen, Juan Tello, W. A. Thurber, Olivier Tostain, Jeremiah Trimble, Thomas Valqui, Barry Walker, D. R. Wells, Bret Whitney, Andrew Whittaker, Dave Willard, Edwin Willis, Susan Willson-Hillman, Kevin Zimmer and Krzysztof Zyskowski; and also to the American Museum of Natural History in New York, the Carnegie Museum of Natural History in Pittsburgh, the Field Museum of Natural History in Chicago, Florida State University, the Louisiana State University Museum of Zoology (and its library), the Museum of the University of São Paulo, the Museu de História Natural de Taubaté, the Museu Paraense Emílio Goeldi in Belém, the Museum of Comparative Zoology (and its library) at Harvard, the Natur Historiska Riksmuseet in Stockholm, the Santa Barbara Museum of Natural History, the United States National Museum in Washington, the Library of the University of Massachusetts, and the Zoological Museum of University of Copenhagen; and last but by no means least BLOWS, the Cornell Laboratory of Ornithology, and the Macaulay Library of Natural Sounds.

Once again, we are very grateful for all the help and support received in different ways from M<sup>o</sup> Josep de Andrés, Dolores Buxó, Juan Antonio Cantí, Cam Christie, Montse Clemente, Fortunato Frías, Conchi García, Olga González, Núria Guevara, Ricard Gutiérrez, Noelia Herranz, Rosa Llinàs, Ana María Lineros, Albert Martínez-Vilalta, Isabel Martínez, Rafael Martínez, Eva Muñoz, Andy Raven, Olga Rius, Pere Rubio, Anna Latorre, Jordi Vidal and Aurea Vilalta. For the eighth volume running, we thank Toni Llobet for the illustration garnishing the back cover.

Finally, we should like to say a few words about the change in the editorial line-up. After 14 years with the project, Jordi Sargatal has decided that now, with the switch from non-passerines to passerines, is the right moment for him to step down in order to be able to concentrate more fully on his important conservation work throughout Catalunya. Nevertheless, he will remain closely attached to HBW from his position on the Editorial Council of Lynx. We thank Jordi for his dedication and his effervescent good humour over these years, and wish him all success with his conservation work.

We are indeed fortunate in having Jordi's ready-made replacement on hand in the shape of David Christie. As many readers will know, David has extensive experience in the world of ornithological publications, not least from the 29 years he spent on the editorial staff of the monthly journal *British Birds*. He has been involved in HBW since Volume 3. At the same time, Teresa Pardo has stepped up from her work in previous volumes concentrated mainly on organizing all matters related to bibliography to take on the new role of Assistant Editor. Both Tere and David have already proved themselves to be indispensable members of the team, so we all look forward with renewed confidence to this second half of the project.

# PASSERIFORMES

## — Eurylaimi

- Eurylaimidae (Broadbills)

Class AVES  
Order PASSERIFORMES  
Suborder EURYLAIMI  
**Family EURYLAIMIDAE (BROADBILLS)**

- Small to medium-sized, arboreal birds, with large head and wide bill, usually slow-moving, many with strikingly patterned plumage.
- 11.5-28.5 cm.

- Afrotropical and Oriental Regions.
- Lowland to montane forest, open woodland, locally extending to cultivation and other more open areas.
- 9 genera, 15 species, 52 taxa.
- 3 species threatened; none extinct since 1600.

### Systematics

Broadbills represent a small family of almost exclusively tropical birds exhibiting a range of distinctive colours and shapes. Their stronghold is in South-east Asia, where they are a characteristic component of the tropical rainforest, usually heard more often than they are seen. Classifying these birds has been another matter entirely. The typical broadbills were originally considered to have affinities with coraciiform birds, such as the rollers (Coraciidae), and with the trogons (Trogoniformes). Moreover, they were even associated with the nightjars (Caprimulgiformes), because of the weight placed on the character of a broad-gaped bill, the obvious source of their English name.

The French ornithologist R. P. Lesson, in 1831, was the first to consider the typical broadbills as representing a separate family. Even so, he placed them in a small division with one other family, which contained only the manakins (Pipridae) and the cotingid genus *Rupicola*, the cocks-of-the-rock, of which the Green Broadbill (*Calyptomena viridis*) was considered to be an Old World representative on the basis of the similarity in the distinctive development of the loreal plumes over the bill. This apparent, superficial relationship of the broadbills with the cotingas, based on a number of other characters, has been noted by several people over the years, but any similarities are now considered to have been independently derived.

By the time the great *Catalogue of Birds in the British Museum* started on passerines, in 1877, anatomical studies had firmly established the broadbills as one of the few families of Old World suboscines, along with the asities (Philepittidae), the pittas (Pittidae) and the New Zealand wrens (Acanthisittidae). When the *Catalogue* volume covering broadbills appeared, eleven years later, additional anatomical investigations had led to the conclusion that there were two main divisions of passerines. These were the Desmodactyli, containing the broadbills alone, and the Eleutherodactyli, in which all other passerines were placed. This arrangement was duly adopted, and for over 80 years the broadbills were therefore set apart in many classifications, briefly as a monotypic order, but usually as a separate suborder at the beginning of the passerine sequence.

During all this activity, it was thought that broadbills were unique to Asia. The African genus *Smithornis*, although it had been known since 1839, was long considered to be just another member of a heterogeneous assemblage of birds broadly known as "flycatchers" and placed together in the family Muscicapidae.

An examination of *Smithornis* by G. L. Bates, however, led to the announcement, in 1914, that broadbills occurred in Africa, and later investigations confirmed this to be the case. Even so, it was not until 1931 that Grauer's Broadbill (*Pseudocalyptomena graueri*) was found to be a eurylaimid, despite possible implications in its generic name; the resemblance to the Asian genus *Calyptomena* had originally been believed to be due to convergence.

The association of the African broadbills with the Asian ones, however, had already been made as long ago as 1853, when another French ornithologist, C. L. Bonaparte, in a revised classifi-

The **Banded Broadbill** is a fairly typical member of this rather varied family in that it is dumpy with a broad head, large eyes, and a broad, flat, hooked bill, as well as an impressively wide gape. Most of the 15 species are brightly coloured, especially the Asian forms, and several show strikingly patterned plumages. The genus *Eurylaimus* is often expanded to include the two Philippine species that herein have been separated in *Sarcophanops*.

Eurylaimidae.

[Figure: Ian Lewington]

cation of birds, proposed Smithornithinae as a third subfamily of the Eurylaimidae, although with the group still placed near the manakins and cotingas. In the first part of his standard work, published three years earlier, he had first named *Smithornis* and had placed it among the "flycatchers". While Bonaparte was at the time still experimenting with his classification, he kept this particular change, but we shall never know if his proposal was the result of insight or coincidence. A few ornithologists accepted the proposal, but by the time a series of anatomical investigations had been initiated, in 1872, Bonaparte's classification had been forgotten.

Although the anatomists of the late nineteenth century firmly believed that the broadbills represented a unique family, the true picture finally emerged in 1971 through a reassessment of the key anatomical characters by S. L. Olson. In reviewing all five characters used to justify the placement of the Eurylaimidae in a separate suborder, Olson found all to be variable among the

broadbills and within the suboscines; he also concluded from his findings that *Smithornis* was the most advanced genus. In addition, Olson commented on the family's similarities with the cotingids, and once more the broadbills, and the asities, too, were placed near the Cotingidae. On the basis of other evidence, however, he considered the pittas to be unrelated to the Eurylaimidae, whereas, by 1982, preliminary findings from DNA studies had suggested that the broadbills and the pittas were closely related families. Five years later, a study of hind-limb myology by R. J. Raikow concluded that the broadbills, the asities and the pittas are all monophyletic, with the asities the sister-group of the broadbills, and the pittas a sister-taxon of a clade that includes the broadbills and the asities. Raikow also remarked that, considering the high taxonomic rank previously accorded to the broadbills, evidence for the hypothesis of monophyly was surprisingly modest. He regarded the uncertain relationships among the genera of the Eurylaimidae as being possibly due to an "underestimation of parallelism in muscular evolution".

In their major 1990 study of the molecular evolution of birds, C. G. Sibley and J. E. Ahlquist found that the DNA-DNA hybridization evidence agreed well with Raikow's findings. The evidence of divergence between *Calypturnomena* and the other genera examined, namely *Eurylaimus* and *Cymbirhynchus*, was noted. As the data were incomplete, Sibley and Ahlquist deferred subdivision of the Eurylaimidae, although they commented that "it seems probable that a family Calypturnomenidae is separable".

From a phylogenetic analysis of 19 syringeal characters, and the two classical osteological characters discussed by Olson, of the broadbills and the asities, R. O. Prum suggested in 1993 that the broadbills are not monophyletic, but instead consist of four clades showing successively closer relationships to the asities. He also noted that an analysis of his data in combination with the myological characters described by Raikow produced the same result. The sister-group relationships of the clades were expressed by Prum as five subfamilies, the fifth representing the asities, usually treated as a separate family. The subfamily Smithornithinae, considered to be the first distinct lineage of the family, appeared to represent a sister-group to all the others, with Pseudocalypturnomeninae the sister-group to the asities, the latter being treated as the "Philepittinae". The traditional subdivision of the green broadbills as the subfamily Calypturnomeninae was retained. The remainder of the broadbills were placed in the subfamily Eurylaiminae, and were considered to represent the sister-group of the Pseudocalypturnomeninae. Prum acknowledged that the interrelationships of the genera within the Eurylaiminae are yet to be resolved, and he regarded the position of *Corydon* as uncertain because he was unable to include a specimen of it in his study.

Olson had also pointed out that none of the broadbill genera appeared to be particularly closely related to any other, and that

One glance at this **Black-and-red Broadbill** and it is not difficult to appreciate how the family came by its vernacular name! Indeed, the scientific name has the same meaning of "broad bill". Most broadbills are insectivorous and carnivorous and the bill is ideally adapted to such a lifestyle. Bill structure varies within the family according to diet. The Black-and-red Broadbill is mainly insectivorous but it also takes small aquatic animals, such as molluscs and freshwater crabs.

VIREO]

their present distribution apparently represented a scattered remnant of specialized species descended from a formerly more widely distributed ancient passerine lineage, possibly representing the oldest remaining passerine group. He noted that the evidence of fossil eurylaimids of undetermined relationships from Lower Miocene deposits in Bavaria, Germany, suggested a re-treating family the ancestors of which probably arose in the Old World tropics during the Tertiary, but were largely replaced by advanced oscines which emerged later, also from the Old World tropics. The massive radiation of suboscines in the New World can be linked to the isolation of South America during the period from the Tertiary to the end of the Pliocene. Thus, Old World suboscines represent specialized remnants.

As one outcome of his study, Prum discussed a complex biogeographical history and evolutionary radiation which suggested that a geographical division of an undifferentiated eurylaimid ancestor led to the primitive genus *Smithornis* and to the common ancestor of all other genera in Asia. Diversification in Asia resulted in the evolution of *Calypptomena*, while a common ancestor spread to Africa, with isolation leading to the relict *Pseudocalypptomena*, but with the Asian lineage evolving into a variety of species. Prum later questioned the fossil record of the broadbills, alleging that the few Bavarian specimens were probably barely identifiable as passerines, and that they had been regarded as broadbills only on the basis of size. Nevertheless, A. Feduccia, in his 1999 revised study of the origin and evolution of birds, continued to recognize the material as being eurylaimid; moreover, he pointed out that these meagre specimens are the only ones within the entire radiation of suboscine birds that are identifiable to the level of a family.

Recent analyses of DNA and other data presented in research results published in 2002 appear to support the southern origins of the passerines, with the Old World relict suboscines as survivors of ancestors that moved northwards from Gondwana over 60 million years ago, through what became Africa. The data sug-

gest that the broadbills are, indeed, closely related to the asities and the pittas, as discussed above. They do not, however, support a relationship of the New Zealand wrens to this group. The results of these latest studies indicate that, rather, the New Zealand wrens were isolated over 80 million years ago and apparently represent a sister-taxon to all other passerines.

Largely through the influence of the 1996 work by F. Lambert and M. Woodcock on the pittas, broadbills and asities, Prum's classification has gained a wider currency. For the time being, there seems little good reason for departing much from it, although it may be considered better to follow the traditional taxonomy for the asities by treating them as a separate family, rather than as a subfamily of the Eurylaimidae. Those authors also reviewed the classification of the species and subspecies, and made several changes from prevailing treatments, including the recognition, once more, of two species of broadbill in the Philippines. A preliminary review of the broadbills by R. W. R. J. Dekker and E. C. Dickinson, published in 2000, used the work of Lambert and Woodcock as a point of reference, but also examined earlier studies. In discussing various problems with subspecies, Dekker and Dickinson preferred to recognise the two Philippine populations of eurylaimid as constituting just one species. At the same time, however, they regarded this species as probably sufficiently distinct from the two other *Eurylaimus* species to merit generic separation, as *Sarcophanops*. Since the plumage and bare-part differences between the two groups are no less marked than are those between *Eurylaimus* and other genera, this proposal seems an acceptable one. The treatment adopted herein represents a reappraisal of all of the above, including some of the suggested changes.

Within the two widespread families of Old World suboscines, the recognition of nine genera for the Eurylaimidae contrasts with the treatment of the Pittidae. Indeed, all 30 species of pitta are conventionally placed in a single genus, although it is very likely that this will be demonstrated to be an oversimplification. Three of the four subfamilies of broadbills are well defined, as each contains just one genus. The fourth subfamily, the Eurylaiminae, encompasses the remaining six genera; as mentioned above, the relationships of these six genera to each other continue to be poorly understood, and further study may well result in the recognition of additional subfamilies. Such a possible outcome would, indeed, help to corroborate the ancient origins of this remarkable family.

The subfamily Smithornithinae, with the sole genus *Smithornis*, is represented by three species. All are stocky, rather short-tailed birds with a superficial resemblance to muscicapid flycatchers, clearly explaining their long association with those birds, although they also possess a distinctive broad, flat bill. Their sombre plumage, with variable amounts of brown, black

The different genera within the family exhibit striking differences in terms of morphology and plumage coloration.

The **Long-tailed Broadbill** with its yellow face, slender green body and long blue tail is unmistakable.

The relationships between genera within the family are unclear, though few, if any, appear to be closely related to one another. Broadbills come from an ancient lineage, being one of the very few families of suboscine passerine found in the Old World. Their present distribution probably represents a scattering of relict species descended from a more widespread older group.

[*Psarisomus dalhousiae* dalhousiae, Khao Yai National Park, Thailand. Photo: Suppalak Klabdee]

The **Rufous-sided Broadbill** is one of three members of the African genus *Smithornis*.

This distinctive genus is characterized by variable, often heavy, streaking of the underparts and upperparts. Their small size together with their rather drab coloration gives them a superficial resemblance to some flycatchers. Indeed, in historical times it took detailed study before they were correctly placed in the Eurylaimidae.

[*Smithornis rufolateralis* rufolateralis, Oban, Nyeri, Nigeria. Photo: A. P. Leventis]

The **Green Broadbill** is one of three members of the genus *Calyptomena*. All are found in the forests of the Greater Sunda subregion, and they may in fact constitute a separate family. They are all predominantly green, compact, short-billed and short-tailed birds. Males have more iridescent plumage with variable black markings. All three have characteristically stiffened loral plumes extending over most of the bill, although this feature is not so pronounced in females, as illustrated here.

and rufous, is highlighted by streaked white underparts, and particularly by the silky-white feather bases on the back, which are fluffed out and visible only when the birds display (see General Habits, Breeding). The widely distributed African Broadbill (*Smithornis capensis*) apparently occurs patchily through West to East Africa and south to north-eastern South Africa. It is currently split into nine subspecies to cover the complex geographical variation found throughout its wide range, but much more study is required in order to delineate these apparent differences. The fragmentary distribution of the African Broadbill in forested regions of West and Central Africa is contrasted with the records from eastern and southern Africa, where subspecific boundaries may be imprecise, but the situation is complicated by habitat loss causing the disappearance of this species from a number of regions (see also Status and Conservation).

The two other members of this Afrotropical subfamily are the Grey-headed Broadbill (*Smithornis sharpei*) and the Rufous-sided Broadbill (*Smithornis rufolateralis*), the former with three subspecies and the latter with two. Both have in common with the African Broadbill a fragmented distribution in the forests of West and Central Africa, and both also are probably more widely distributed, although neither occurs in southern Africa. Unlike their congener, however, they are more specialized as forest species. Recent evidence, such as that from vocalizations, has indicated that the Grey-headed Broadbill is more closely related to the African Broadbill. While some authors have considered the African and the Rufous-sided Broadbills to represent a superspecies, the evidence for this relationship has been refuted, again by such factors as vocalizations and the sounds produced by the primaries (see Voice).

Three congeneric species make up the subfamily Calyptomeninae. All are plump green birds with a short bill, a very short tail and a tuft of forward-projecting loral plumes, the latter more prominent on the males. The subfamily is confined to South-east Asia, where the smallest of the three species, the Green Broadbill, ranges from south Myanmar to Sumatra and Borneo and some offshore islands, and is divided into three subspecies. It is on several of these offshore islands, off western Sumatra, where the most distinctive form, *siberu*, is found. The notable difference in colour and size of this subspecies could even suggest that it is a different species. In Borneo, where the situation becomes more

complicated, the Green Broadbill is found mostly in the lowlands, whereas its two congeners live in the mountains, Hose's Broadbill (*Calyptomena hosii*) chiefly at mid-elevations, with Whitehead's Broadbill (*Calyptomena whiteheadi*) usually occurring at the higher elevations. There is some altitudinal overlap among the three, but the sequence is, in broad terms, from the smallest of the species at the lowest levels to the largest at the highest, representing a characteristic evolutionary development among birds living on islands which are big enough to cover a range of altitudes. This is a development more familiar on some other large islands, such as New Guinea. The situation on Borneo is not, however, a perfect one. While both Hose's and Whitehead's Broadbills are widely recorded from the higher elevations of Borneo, and do overlap in many places, there are some gaps in this distributional pattern. How much of this is the result of a lack of field observations, or of differences in habitat requirements, is yet to be resolved.

With eight species in six genera, the subfamily Eurylaiminae is the largest of the family. As already mentioned, the interrelationships of these genera are not clear, so that their placement together is still tentative; similarly, the sequence in which they are placed is necessarily somewhat arbitrary, but there seems no reason to dispute that followed by Lambert and Woodcock. The genus *Cymbirhynchus*, containing the Black-and-red Broadbill (*Cymbirhynchus macrorhynchos*), is generally characterized by its colour pattern of largely black upperparts and maroon underparts, and a bright blue-and-yellow bill. Confined to South-east Asia, where it ranges from south Myanmar and south Vietnam south to Sumatra and Borneo, it has been found only in lowland rainforest, with an apparent specialization towards forested areas close to rivers and streams. There is some variation in this species' plumage characters, normally summarized as the recognition of four subspecies; nevertheless, although geographical trends are apparent, the extent of individual variation remains to be clarified.

A very distinct member of the family, appearing as a slim and long-tailed bird in green, yellow and blue, the Long-tailed Broadbill (*Psarisomus dalhousiae*) has a wider range than the previous species, extending from the foothills of northern India across to south-east China and Indochina and south to Sumatra and Borneo. An understanding of the geographical variation of

The members of *Eurylaimus* are usually encountered in pairs, like this male and female **Black-and-yellow Broadbill**, or in small family groups. Nevertheless, parties of up to 15 birds have been recorded, and the density of individuals in a forest can be surprisingly high. Inside the forest, calling individuals often trigger a loud chorus of responses from nearby birds. Black-and-yellow Broadbills occasionally join up with mixed-species feeding flocks that pass through their territory.

this broadbill is incomplete. At present, five subspecies are generally accepted, but the evidence suggests that at least two more are required in order to express the nature of the variation involved.

*Serilophus*, the third genus of the subfamily Eurylaiminae, is, like the previous two, monotypic. Its sole representative, the Silver-breasted Broadbill (*Serilophus lunatus*), is a small species of more subdued plumage but with some contrasting features, such as the blue, black and rufous markings on the wings. It has a range similar to that of the Long-tailed Broadbill, but it is absent from Borneo. The geographical variation of the Silver-breasted Broadbill is complex, resulting in more subspecies having been described for this species than for any other member of the family. Of the ten subspecies normally considered to be valid, four occur in Myanmar, and it is there that the defining of the boundaries between the subspecies has been particularly difficult. The distinctive western race *rubropygius*, extending from India to north Myanmar, was long considered to represent a separate species, chiefly because of a presumed range overlap with the nominate race in north Myanmar. A recent careful examination of the relevant details enabled it to be demonstrated that these different forms do in fact occur close to each other, but without overlapping in distribution. As a consequence, it is now generally agreed that all the forms should be treated as subspecies of the Silver-breasted Broadbill. Furthermore, apart from complexities concerning geographical variation in Myanmar, the status of Indochinese populations, notably those in Laos, remains to be resolved.

The two species in the genus *Eurylaimus*, again confined to South-east Asia, are the Banded Broadbill (*Eurylaimus javanicus*) and the Black-and-yellow Broadbill (*Eurylaimus ochromalus*). The former occurs from south Myanmar and Indochina south to Java and Borneo. It is a large species with a purplish head and underparts and yellow streaking above, but with some geographical variation represented by the recognition of five subspecies. The feature of a black chestband on the male is absent in Javanese birds. This lack of a black band, along with a number of other features, suggests that the population in Java, where the avifauna characteristically exhibits a higher degree of endemism than is found in Sumatra or Borneo, may represent a separate species. From an evolutionary viewpoint, the Javanese Banded Broadbills are notable because the male clearly has a "female-

like" plumage, a phenomenon demonstrated by various island populations of several polytypic species.

Smaller than the previous species, and with a similar but less extensive range, the Black-and-yellow Broadbill, as its name suggests, has contrasting black and yellow plumage markings. Perceived geographical variation in this species has resulted in two isolated populations, one on the islands off north-western Sumatra and the other in a small region of Sarawak, in Borneo, being treated as subspecies in some recent works. This, however, would seem to be incompatible with a general picture of the variation of this broadbill, which appears to be more individual than geographical in nature, and there seems to be no valid reason to recognize any subspecies.

The genus *Sarcophanops* contains two closely related species, both confined to the Philippines. Until recently, these two forms were usually regarded as conspecific, but it is considered better to treat them as two separate species forming a superspecies. Moreover, many authors have preferred to merge the genus with *Eurylaimus*, although not always with any real conviction. On the basis of a number of morphological characters, in particular the prominent blue wattle around the eye, found on no other eurylaimid species, the generic separation of the Philippine broadbills is considered probably a better taxonomic treatment. This also reflects the isolation of the main archipelago, where a significant percentage of endemic taxa, including genera, occurs; *Sarcophanops* provides a further striking example of a genus restricted to the Philippines. The Mindanao Wattled Broadbill (*Sarcophanops steerii*) is found on Mindanao and the nearby islands of Basilan, Malamaui, Siargao, Poneas and Dinagat; while two subspecies are normally recognized, the differences between them may be slight. The Visayan Wattled Broadbill (*Sarcophanops samarensis*) is confined to Leyte, Samar and Bohol, north of Mindanao.

The monotypic genus *Corydon*, the sixth and last of the subfamily Eurylaiminae, is represented by a remarkable member of the family, the Dusky Broadbill (*Corydon sumatranus*). It is the largest of the broadbills, a blackish, thickset bird with a massive bill; in fact, it has proportionately the broadest bill of all the passerines. As most eurylaimids, the Dusky Broadbill is confined to South-east Asia, occurring from south Myanmar and Indochina south to Sumatra and Borneo. It exhibits considerable variation throughout this range, and eight subspecies have been described.

Much of this variation, however, appears to be individual, and, while the extent to which it can be interpreted as being geographically based is rather difficult to determine, it seems likely that no more than three or four subspecies are involved. The characters include a dorsal spot which varies in colour from scarlet to orange, but the significance of this normally concealed colour character is yet to be determined.

Finally, the fourth of the subfamilies, Pseudocalyptomeninae, contains a single species, Grauer's Broadbill. This is an isolated, relict species living in the mountains of the eastern region of Central Africa, an area notable for a number of rare and unique bird genera and species. When it was first reported, this extraordinary bird, discovered in 1908, was thought by its describer to be a highly aberrant flycatcher, partly because it had ten primaries, and broadbills were as yet unknown in Africa. The generic name given to it, *Pseudo-calyptomena*, was in allusion to what was thought to be a superficial similarity in colour and shape to the green broadbills of the Asian genus *Calyptomena*; that it was later shown to be related to them after all is something of an irony. The two discrete populations of Grauer's Broadbill, one in eastern Zaire and the other in west Uganda, appear to differ to some extent in their habitat preferences (see Habitat) and in certain aspects of their behaviour (see General Habits). Although currently not even separated as different races, further research may show that they are close to becoming two separate species.

### Morphological Aspects

Broadbills are thickset birds with a broad head, large eyes, a broad, flat, hooked bill and a wide gape. Most of the 15 species have strikingly patterned plumages featuring greens, blues, maroons and yellows, these colours usually being duller on the females, and in size and shape they range from being similar to flycatchers to having a resemblance to rollers.

The African *Smithornis* broadbills and the *Calyptomena* green broadbills are all sexually dichromatic, whereas the sexes of Grauer's Broadbill are similar. Of the remaining eurylaimids, sexual dichromatism is most pronounced in *Eurylaimus* and *Sarcophanops* and is slight or absent in the other genera. The significance of these differences between genera is unclear, but it seems likely to be connected with differences in breeding behaviour (see Breeding).

The wide bill and gape are well suited for the insectivorous and carnivorous diet of most eurylaimids. The three green broadbills of the genus *Calyptomena*, however, have become frugivores (see Food and Feeding), having lost the wide bill while retaining the wide gape, but this specialization has meant that, as they are unable to manipulate large fruits with the bill, they must swallow these whole.

Recognition of the Eurylaimidae as passerines began with studies of their pterylosis and palate structure. They were subsequently set apart from all other passerines because, in the structure of the foot, the deep plantar tendons were joined by a vinculum, and also because the manubrium (spina externa) of the sternum was a simple rod and was not forked. It was thus the determination of the presence of a plantar vinculum that led scientists to the realization that the African species were, in fact, members of this family. The three other characters long thought to be unique to broadbills are the possession of 15, rather than 14, cervical vertebrae, a weak hallux, and the absence of a cup-and-ball joint in the quadrato-jugal articulation. The review of these characters, and the additional evidence provided by subsequent anatomical and molecular studies, as noted above (see Systematics), have restored the broadbills to their original placement close to the other Old World suboscines.

The three African species in the genus *Smithornis* are characterized by variable amounts of streaking in their plumage, both on the darker upperparts and on the lighter underparts. The overall effect is to produce a superficial resemblance to some flycatcher species, making their earlier classification with that group understandable, even though the broad, flat bill is distinctive. Further, the hidden white feathers on the back, which can be fluffed out, is a feature shared with some wattle-eyes

(Platysteiridae), a group previously placed in an expanded Muscicapidae family. All three *Smithornis* species have stiff, twisted outer primaries, those of the Rufous-sided Broadbill being particularly narrow at the base. These outer primaries vibrate during display-flights (see Voice, General Habits), producing a mechanical, buzzing trill that sounds more musical from a distance and was long thought to be a vocalization.

In contrast to those three species, the *Calyptomena* green broadbills are compact, short-billed, short-tailed birds having a predominantly green plumage, iridescent in the males, and with variable areas of black, or black markings. Hose's Broadbill is extensively blue on the underparts, while the island form *siberu* of the Green Broadbill has a bright blue wash, particularly on the underparts. The black markings are more pronounced and better developed on the males, and are most extensive on the male Whitehead's Broadbill. All three species have the characteristic stiffened loreal plumes extending over most of the bill, although this feature is less developed on females. In Borneo, where all three occur, with some altitudinal overlap, they exhibit a distinct gradation in size: the Green Broadbill is 14-17 cm long and weighs 43-72.8 g, Hose's Broadbill is slightly bigger at 19-21 cm and 92-115 g, while the largest, Whitehead's Broadbill, measures 24-27 cm and weighs as much as 142-171 g.

Bearing a superficial resemblance to the Asian green broadbills, Grauer's Broadbill shares with those the compact shape and the predominantly green plumage, with some blue on the underparts. Its tail, although relatively short, is longer than that of *Calyptomena*. Unlike the latter, however, the African species has no development of loreal plumes over the bill, which is less specialized, reflecting its mixed insectivorous and frugivorous diet (see Food and Feeding). The pectoralis major, the muscle required for executing downstrokes, is well developed in this species, suggesting an ability to perform aerial displays analogous with those of the Asian green broadbills or, perhaps more likely, the other African eurylaimids (see General Habits), although no such displays have been documented for Grauer's Broadbill.

All other broadbills, thrown together in the subfamily Eurylaiminae (see Systematics), and with mostly overlapping distributions in South-east Asia, exhibit a range of sizes and

**The Silver-breasted Broadbill** exhibits slight sexual dichromatism. The female bird, pictured here on the right, shows a thin, often broken, silver breast band. The extent of sexual dichromatism in the broadbills varies, being most pronounced in the genera *Calyptomena* and *Smithornis*. Of the remaining broadbills it is also exhibited by *Eurylaimus* and *Sarcophanops* but is slight or absent in the other four genera.

[*Serilophus lunatus stolidus*,  
Kang Krajam National Park,  
Thailand.  
Photo: Suppalak Klabdee]

weights matching that of the green broadbills in Borneo. It is uncertain if there is any significance in this pattern, although it may be linked with ecological separation (see Habitat). The Black-and-red Broadbill, with its contrasting black upperparts and maroon underparts, also has white wing patches which are conspicuous when flashed in flight. It is normally found in forested areas near rivers and streams, and it is interesting that many avian species specializing in riverine habitats feature flashes of white in their plumage, believed to be an adaptation enabling contact between individuals in areas where sound may be muted by the noise of flowing water. Unlike many such species, however, this broadbill does not have high-pitched calls, and it is probably only secondarily adapted to these habitats, perhaps through competition with other broadbills.

Superficially somewhat similar to the Black-and-red Broadbill, the Banded Broadbill lacks that species' white wing patches, instead having conspicuous yellow markings on its back and wings. In Java, where no other broadbill occurs, the male has lost the black chestband and is similar to the females of the other four subspecies of the Banded Broadbill. Thus, the Javan male is "hen-feathered", an indication that, with a lack of competition, distinctive sexual dichromatism became of lesser importance. The phenomenon of otherwise sexually dichromatic birds developing "hen-feathered" males in parts of their ranges is known also from islands farther east, as demonstrated by, for example, some races of the Golden Whistler (*Pachycephala pectoralis*). Such a conspicuous morphological development is also sometimes considered as evidence that a population may have evolved into a separate species, and this may be the case with the Banded Broadbill.

The congeneric Black-and-yellow Broadbill, at 13.5-15 cm and 31-39 g, is only half the size of the Banded Broadbill, which is about 22 cm in length and weighs up to 87 g. While sharing with the latter the conspicuous yellow markings on the upperparts, it is otherwise a darker bird.

An early derivative of these eurylaimids has been long isolated in the central and southern Philippines, where it is now represented by two species (see Systematics). The most remarkable feature of the wattled broadbills, and one found in no other eurylaimids, is the development of a ring of large blue wattles around the eye. Such integumentary structures as wattles have evolved independently in a number of bird families, including several, such as the asities in Madagascar, which have been isolated for a lengthy period of time on islands. The wattles may have a display function, but this has not as yet been shown to be the case. Both of the Philippine species have generally dark upperparts, and, whereas the males have pinkish underparts, the females are white below.

The largest member of the family, the Dusky Broadbill, is dark blackish in colour but with a contrastingly lighter throat patch and a fairly prominent white wing patch. The big, hooked bill is conspicuously pinkish, as also is an area of bare circumorbital skin. This species has a variably red or orange dorsal spot, which is generally invisible in the field. The function of this is unknown, but it may, again, be linked with display.

At the opposite extreme in terms of morphology and plumage coloration, the slender, green-bodied, blue-tailed Long-tailed Broadbill, with its striking head colour of yellow and black, is unmistakable. This aptly named eurylaimid has a tail that is up to 15 cm in length, the longest of any member of the family. Perhaps equally attractive in its own way, the Silver-breasted Broadbill is mostly silvery grey in colour, with darker upperparts and blue, black and rufous markings, and a conspicuous black eyebrow. The combination of these colour characters exhibits much variation over its large range. Apart from its absence from Borneo, this species has a very similar distribution to that of the larger Long-tailed Broadbill, with which it co-exists in many places (see Habitat).

Juvenile plumages of all eurylaimids are similar to those of the adults, differing only in being duller and, in some cases, shorter-winged and shorter-tailed. Unfortunately, but by no means surprisingly, there appears to be a dearth of information on the moult strategies of the Eurylaimidae. Adults moult the flight-feathers and the tail feathers after breeding, but little else has been documented.

## Habitat

The Eurylaimidae are widespread in the Palearctic, where they are all specialized forest birds. A few species extend marginally into other habitats, and the Long-tailed and Silver-breasted Broadbills inhabit subtropical forest in the northern parts of their ranges. Only the African Broadbill occurs extensively outside forest, and in a small area where it ranges outside the tropics, in southern Africa, it can be found in woodland and scrub.

Several species have been recorded from plantations and cultivation, and even around villages, but such occurrences are normally confined to foraging activities. Nevertheless, there are instances of eurylaimids breeding in more open areas, such as Black-and-yellow Broadbills nesting in tree plantations, but events of this kind are very unusual. The only species showing any tolerance of relatively open habitats on a more regular basis is the Black-and-red Broadbill, but this appears to be a consequence of its preference for localities near water, with some cover, and even then never too far from forest.

The broader range of habitats occupied by the African Broadbill covers evergreen forest, riparian forest, dense savanna woodland, bamboo stands, deciduous thickets, coastal bush, disturbed forest and scrub mosaics, and patches of montane forest, including areas dominated by tree-ferns. Locally, it extends into cultivation and tree plantations, and into vegetation around villages. It will also enter logged forest, and has even been recorded in pine (*Pinus*) plantations, as, for example, in Zambia. Although this species occasionally occurs in primary forest in East Africa, this is in contrast to the situation farther west, where the presence of its congeners restricts it to drier areas outside the main evergreen forest. The altitudinal range within which the African Broadbill is found is wide, ranging from sea-level, as in the coastal woodland of south-eastern Africa, up to 2550 m, as in parts of the interior. It seems generally, however, to prefer much lower elevations, and particularly those below about 700 m, although the E African subspecies *medianus* is strictly a montane bird.

Primary forest and relatively undisturbed secondary forest are the main habitats of the two other *Smithornis* broadbills, both of which are distributed over a smaller range than the African Broadbill. Both will also enter old logged forest. The Grey-headed Broadbill, while recorded at up to 1950 m, prefers mid-montane levels, although much variation has been noted in this respect, particularly from surveys conducted in Cameroon. Its relative, the Rufous-sided Broadbill, exhibits a preference for dense undergrowth near water, and has also been found in old plantations. It inhabits mainly lowlands, only locally ascending as high as 1500 m.

The last of the four Afrotropical eurylaimids, Grauer's Broadbill, occurs in two isolated populations which display some difference in habitat preferences. In east Zaire, this Vulnerable species is found in montane forest, including areas of bamboo, and also in trees in clearings and cultivation, at elevations of 1760-2480 m; it is, however, usually observed below the bamboo zone, and especially at forest edges. Several observers have commented that, in Zaire, this species shows an apparent tendency to prefer dense foliage and the upper branches of tall trees, at levels of 7.5-23 m above the ground. In neighbouring Uganda, on the other hand, Grauer's Broadbills mostly live at higher altitudes, at 2060-2285 m, where they seem to exhibit a distinct preference for areas of primary forest that are dominated by *Chrysophyllum gorungosanum* trees growing on steep slopes. Moreover, the Ugandan birds appear to be associated more with the lower strata of the forest, usually occupying the upper level of the understorey at about 2.5 m.

In Asia, primary and secondary forest harbours all three of the *Calptomena* green broadbills, which are true forest specialists. The Green Broadbill is sometimes seen in other types of forested habitat, or in plantations and logged forest, but perhaps only when making foraging excursions. It is a lowland species, usually found below 700 m, but ranging locally up to 1700 m. Its two congeners are both confined to Borneo, where the slightly larger Hose's Broadbill ascends to about 1680 m, but usually occurs at about 600-1220 m, whereas Whitehead's Broadbill, the biggest of the three, ranges from 600 m to 1980 m, but is found

**Green Broadbills** are predominantly tropical-forest specialists like most other members of their family. Broadbills inhabit a wide range of undisturbed forested habitats at altitudes up to 2500 m.

Some exhibit strong habitat preferences, such as the Black-and-red Broadbill (*Cymbirhynchus macrorhynchos*), which favours riparian forest. Only a few species extend into marginal habitats.

Where a number of broadbill species exist together competition is reduced by differences in size, weight and bill morphology. In Borneo, where all three species of *Calyptomena* occur together, they differ in size and weight and show altitudinal preferences that effectively separate them.

[*Calyptomena viridis*.  
Photo: Roland Seitre/Bios]

Broadbills are not spectacular songsters but instead possess a functional range of vocalizations. The **Dusky Broadbill** occurs in small close-knit groups that are highly vocal, and this habit often leads to their detection high in the canopy. Dusky Broadbill vocalizations include a distinctive series of six to eight screaming notes on an ascending scale and a variety of whistles. The African genus *Smithornis* supplements its vocalizations with an array of mechanical noises produced with an emarginated primary whilst displaying. Interestingly, such mechanical sounds are also made by the closely related asities (*Philepittidae*) of Madagascar.

chiefly at 900–1700 m. The latter prefers tall growth in montane forest, and avoids stunted forest.

Several of the Asiatic eurylaimids are less restricted in their choice of habitat. The Black-and-red Broadbill, for example, is found in a diversity of lowland forests, including mangroves, as well as in plantations, and it also occurs locally in and around villages and gardens. In all cases, however, it is usually found only near rivers, streams and flooded areas. These habitats are utilized even if they have suffered disturbance, so long as there is an element of forest habitat, particularly some tall trees, remaining. This species ranges locally to 900 m in Borneo and Sumatra, but is otherwise a denizen of the lowlands up to 300 m.

The Long-tailed, Silver-breasted, Banded and Black-and-yellow Broadbills occupy a wide range of evergreen and deciduous forests. The first of those species can also be seen at the edges of pine forest and in areas dominated by bamboo, with altitudinal migrants (see Movements) wandering into more open areas and gardens, while the second has been recorded in pines, oak (*Quercus*) and bamboo and also enters logged forest, cultivations and gardens. In the Indian Subcontinent, Long-tailed Broadbills have been thought to show a preference for areas near water but lacking extensive undergrowth, although this seems not to have been noted elsewhere in the species' large range. Both the Long-tailed and the Silver-breasted Broadbills extend over a wide altitudinal band. The former reaches about 2000 m in much of its range, being mainly a montane bird in southern Peninsular Malaysia, Sumatra and Borneo, but its mainland populations are generally found at mid-montane levels. Similarly, the Silver-breasted Broadbill occurs from the lowlands to 2230 m, and is largely a montane species in the southern parts of its range.

A more definite liking for the proximity of rivers and streams is shown by the Banded Broadbill, which is not infrequently seen in plantations, gardens and villages, as well as in evergreen and mixed deciduous forests. Its single congener, the Black-and-yellow Broadbill, also extends into secondary forest, plantations and logged forest, particularly if some large trees survive. Both of these species are lowland birds, the Banded Broadbill occasionally reaching to 1500 m, while the Black-and-yellow Broadbill ascends to no more than 900 m in Sumatra and about 1220 m in Borneo.

Like the previous four species, the Dusky Broadbill inhabits a variety of evergreen and deciduous forests, reaching the edges of plantations and mossy forest at higher altitudes. There is evi-

dence to suggest that it prefers areas near rivers and streams. Throughout its range, this large eurylaimid has been recorded at higher elevations of up to 2000 m, notwithstanding which it is normally a lowland bird.

In the Philippines, the two wattled broadbills are chiefly forest inhabitants. Indeed, the Visayan Wattled Broadbill is apparently restricted to primary forest, including forested limestone outcrops, in the lowlands, with local records at up to 750 m. The Mindanao Wattled Broadbill is found in evergreen forest, including remnant patches, and in secondary forest, particularly near rivers, but it occurs also in mangroves. Although normally found well below 1000 m, it has been recorded at up to about 1220 m.

It is fairly clear from the details outlined above that broadbills have a limited tolerance of disturbed areas. Within forested environments they inhabit a wide range of types, but lowland evergreen forests include the most favoured types. Apart from the Black-and-red Broadbill, several other members of the family show a particular liking for forested areas near water, but none is so clearly specialized in this habitat preference as is that species. While most eurylaimids range into higher elevations, the bulk of their populations is found in lowland areas. All the same, several species which demonstrate a preference for lowlands in many areas have discrete populations which are restricted to montane regions. The extent of altitudinal variation in habitat selection, even within individual species, may be the result of competition, but this is unclear and further study is required.

The broadbills in the subfamily Eurylaiminae (see Systematics) overlap widely in distribution in South-east Asia, and several species often occur together in the same habitats. All eight are adapted to similar feeding strategies, combining sit-and-wait aerial sallying and active gleaning of branches and leaves (see Food and Feeding), but they differ in size and weight in much the same way as do the green broadbills in Borneo (see Morphological Aspects). There is some evidence of a correlation between increasing size and higher foraging levels, but this pattern is not exclusive and is dependent on which other species are present and on the type of forest habitat occupied.

The Banded and the Black-and-yellow Broadbills overlap throughout much of their ranges, but the former is twice the size of its congener. The two co-exist by feeding on the same prey, but of different sizes, as demonstrated by a study in Borneo. Where the Long-tailed Broadbill overlaps in distribution with other

**Green Broadbills**, along with the other two members of the genus *Calyptomena*, differ markedly from other broadbills in that they are obligate frugivores. This is reflected in the structure of their bills. In this genus the bill is much smaller than in other genera, but the birds still have a characteristically wide gape which allows fruit to be swallowed whole.

Green Broadbills have a marked preference for figs (*Ficus*) but they will take other kinds of fruit.

Studies of this species in Peninsular Malaysia demonstrated that the species fed on the fruit of 21 species of fig, ranging in size from 5.4 x 5.9 mm to 32.4 x 27.4 mm. Seeds are regularly regurgitated.

Radio-tracking showed that the birds spent the majority of their time in the vicinity of suitable fruiting fig trees. Green Broadbills forage in pairs or small groups usually in the lower and middle storey but they also enter the canopy of trees that are in fruit. They usually pluck fruit in short flights but exceptionally take fallen fruit from the ground.

All three *Calyptomena* broadbills will also feed opportunistically on invertebrates, for instance at termite swarms, and invertebrates are an important part of the diet of nestling birds.

Most broadbills are insectivorous. Prey items, such as the stick-insect held by this **Black-and-yellow Broadbill**, are typically captured in the air, or from foliage, during short flights from exposed perches. Although each species demonstrates a preference for certain prey items, they all appear to feed opportunistically. The larger species, in particular, are likely to take any small animal that presents itself. The bulk of the diet of most species is made up of insects, for instance orthopterans, beetles, bugs and hymenopterans, as well as their eggs and larvae. Other invertebrates such as millipedes, spiders, snails and small crabs are also taken. Some species also take small vertebrates like tree-frogs and lizards and even, in one case, small fish. Although the three *Calyptomena* species are the only obligate frugivores, the other broadbills probably all occasionally take a proportion of fruit. Indeed, fruit may be locally important for some of these other species, as for the Banded Broadbill (*Eurylaimus javanicus*) in Sumatra and Java.

[*Eurylaimus ochromalus*,  
Gunung Palung  
National Park,

Photo: Tim Laman]

All broadbills have feeding strategies that combine aerial sallying from exposed perches, foliage-gleaning, and also quick flights to grab prey from branches or leaves. Most species feed in the middle storey but are occasionally found at all levels. Broadbills usually forage singly or in pairs, but they can be quite gregarious, sometimes associating with mixed-species feeding parties. Some species such as the **Silver-breasted Broadbill** form loose feeding flocks outside the breeding season.

broadbills, it is normally found at higher elevations, but the situation is less clear in Indochina. The same applies to the Silver-breasted Broadbill. Although very different in appearance, those two species have very similar distributions and habitat requirements. Their ability to co-exist is evident from their sizes: the Long-tailed Broadbill is 23-26 cm long and weighs up to 67 g, the corresponding figures for the Silver-breasted Broadbill being 16-17 cm and about 25-35 g.

### General Habits

What is known of the general habits of broadbills is largely a collection of anecdotal observations centred on feeding and breeding activities, a fact which applies equally to many other birds of tropical forest. While more extensive observations have been made on the Green Broadbill, these are based largely on a study of captive individuals. Some details of displays have been recorded for broadbills in Africa, but little relevant information is available for the Asian species. The picture emerging from the scattered data suggests that there are more similarities among the members of the family than may be indicated by other evidence. Moreover, a paucity of data on the lives of many tropical birds is all too familiar when compiling information for a large number of bird families. Unfortunately, the opportunities for further study of these birds are decreasing, but, if they are to survive and prosper in the remaining tropical forests of which they are a very integral part, such information is vital for the management of these habitats.

Broadbills characteristically perch quietly in concealed locations, usually in the foliage of trees. They may be first detected by their calls, commonly given in the early mornings and late afternoons but, in some cases, at various times throughout the day. The majority of members of this almost exclusively tropical family of birds are most active during the earlier and later parts of the day. Several appear, in fact, to be almost semi-crepuscular in their activity. The Dusky Broadbill, for example, is generally far more likely to be seen and heard in the early part of the morning and late in the evening, while the Silver-breasted Broadbill, at least in the northern parts of its range, also tends to be rather crepuscular.

Similarly, since these birds tend to be rather shy, little has been published on any aspects of their comfort behaviour. The

Green Broadbill has been observed to bathe in puddles and forest streams with a relatively high degree of frequency, but few other details are available.

Many eurylaimids are gregarious and are often found in small flocks, this being particularly true of the Dusky Broadbill, which seems invariably to live in groups of up to ten individuals, while flocks of 20 have been recorded. Long-tailed Broadbills normally occur in flocks of up to 15 or so individuals, but as many as 40 have been seen together in the Indian Subcontinent. Similarly, groups of up to 20 Silver-breasted Broadbills and of up to 15 Black-and-yellow Broadbills have been reported. Even the poorly studied Grauer's Broadbill is known to occur at times in small flocks of up to ten individuals, although it is frequently encountered singly. In keeping with their generally sociable nature, the majority of broadbills will readily join mixed-species flocks when these bird waves pass through their foraging areas, and it is likely that all eurylaimids do this from time to time as part of their regular foraging activities. The habit is perhaps commoner among the insectivorous broadbills.

It is unclear whether or not breeding and foraging territories are maintained by all broadbills. The display-flights of the African broadbills of the genus *Smithornis*, for example, appear to have a territorial function. In Borneo, however, at least two species of green broadbill can be found in small numbers in the same fruiting trees.

When at rest, eurylaimids perch in a squat position with the head tucked in. The Dusky Broadbill will sit quietly for hours in this posture, with the neck drawn in and the bill pointing upwards. Recently, one observer, in noting similar behaviour by the Silver-breasted Broadbill, remarked that this apparent lack of fear can offer good viewing opportunities for birdwatchers. In contrast, this type of behaviour elicited a rather different response from the ornithologist and collector W. Davison, who commented, in 1878, that the broadbills "might well be designated a stupid set of birds". In this context, Davison thought that Silver-breasted Broadbills were the most stupid of the lot: "They usually move about in small parties, and when one meets with a party, every bird of which it consists can, without difficulty, be secured, as the birds take no notice of their companions being shot, and do not appear to be at all alarmed at the report of the gun, seldom moving further than the next branch, sometimes not moving at all, when the gun is fired." This "stupid" behaviour, so called because it makes it easy to shoot the birds, was noted by Davison

#### Green Broadbills

regularly come to the ground to bathe or drink at small puddles, pools and streams in the forest. They have also been observed taking fallen fruit from the forest floor but such behaviour appears to be rather rare. The bright green plumage of this genus, which looks so striking in illustrations, is in fact extremely cryptic amongst the plentiful foliage of the middle and upper storeys, whereas on the ground it can make for rather poorer camouflage.

[*Calyptomena viridis viridis*, West Kalimantan, Borneo. Photo: Martjan Lammertink]

also for the Dusky Broadbill, flock-members of which would, like those of the Silver-breasted Broadbill, "allow themselves to be shot one after the other without any attempt to escape".

A century later, the Philippine ornithologist D. S. Rabor discussed a similar kind of behaviour by the Mindanao Wattled Broadbill. He commented that, once the observer or collector had discovered a group of these birds, it would be easy to collect them in a particular spot in the forest. This was because, in spite of the noise produced by the first shot, the remaining birds would continue to perch in exactly the same places as they had been before being discovered. The other flock-members would remain nearby and act "stupidly", and it would be some time before the group finally left the site.

Davison was kinder to the Green Broadbill and pointed out that, while not shy, it was not stupid like the other broadbills. Interestingly, it is for Green Broadbills that the most remarkable behaviour has been observed (see also Breeding), much of the information having been derived from observations made on captive individuals. An extraordinary spinning display performed by the male, usually after repeatedly "ricocheting" around its aviary, is apparently seasonal in occurrence, having been documented only for the period from December to July. From a perch about 50 cm above the ground, the male locates the female on her usual perch a metre or so higher and to one side, briefly flashes his wings, and then rapidly ascends vertically to a large branch on the ceiling of the aviary; here, with his bill open wide, he spins around, occasionally touching the branch with his bill. After several such "beak pirouettes" over a period of five to ten seconds, the male moves to another display perch. Although the female may watch this display, she appears not to respond to it.

Far less is known about the behaviour of the two other *Calyptomena* species. In one observation of Whitehead's Broadbills, at least three males sat on small horizontal branches just below the canopy and were calling almost continuously. Two of the males were perched closely together and apparently competing as they called, while the other male which was visible was calling from a different branch nearby. Although Hose's Broadbill is known to bob the head and neck when calling, virtually nothing else is recorded of its behaviour. It does, however, seem quite possible that all three species of green broadbill share similar ritual displays and breeding behaviour.

In the Afrotropics, the three *Smithornis* species have an interesting display-flight. That of the African Broadbill, apparently performed by both sexes, takes the form of a short flight on an elliptical horizontal path, with a diameter of about 60-80 cm, and is repeated with a frequency of about one flight every 45 seconds. During this aerial display, the feathers of the lower back are puffed out, making the white feather bases very conspicuous, while at the same time the stiff, twisted outer primaries vibrate, producing a mechanical-sounding whistle loud enough to be audible up to 60 m away (see Voice). The flight is sometimes immediately preceded by an upward leap, in which the bird jumps vertically up to 25 cm above the perch. Although usually associated with breeding, these aerial displays have been recorded throughout the year in some regions. The display-flight of the Grey-headed Broadbill is similar, but on a circular, rather than elliptical, flightpath (see also Breeding).

Although the courtship display of the Rufous-sided Broadbill is different from that of the African Broadbill (see Breeding), its aerial display is very like the latter's. The display-flight is performed in all months of the year, and by both sexes, although more frequently by the male, and is seen most often at dawn and dusk. In West Africa, it was found that display periods normally started before dawn and continued until about 09:00 hours, before resuming in the late afternoon and continuing until dusk; at other times of the day, displaying was recorded only sporadically. The flight is started from a horizontal perch 5-15 m above the ground. The bird first makes one or two abrupt jumps into the air, sometimes turning in mid-jump, before flying on an elliptical path, measuring about 1 m across, which takes it back to the same perch. Again, the white of the back feathers is exposed, and the stiff, twisted, narrow-based outer primaries produce a mechanical trill audible to a distance of 150 m. The tone of this sound changes according to the angle of the flight ellipse, which varies from being level to inclining upwards at an angle of 45 degrees.

Observations have shown that the aerial display of one Rufous-sided Broadbill provokes the same display by another, thus demonstrating that these display-flights have a territorial function. Although the male may continue to make display-flights from the same perch, it is more likely that he will use a succession of perches, when he can then cover a distance of up to 1.5 km in approximately 15 minutes. Typically, flights are made at one-minute intervals for a period of about an hour, but the fre-

There is some evidence of polygyny in the *Calyptomena* broadbills of South-east Asia and the *Smithornis* broadbills of Africa. Males of both genera appear to have elaborate displays and may in fact compete against each other at individual or group lekking grounds. Tropical-forest birds that engage in lekking behaviour usually exhibit strong sexual dimorphism, and this is apparent in *Calyptomena*. The black wingbars of male **Green Broadbills** readily distinguish them from the generally paler females.

[*Calyptomena viridis*.  
Photo: Roland Seitre/Bios]

quency can be doubled if other individuals are displaying nearby. One Rufous-sided Broadbill averaged one flight every 30 seconds for a total of 14 minutes.

Although the poorly known Grauer's Broadbill is presumed, on the basis of the development of its pectoral muscles, to have distinctive displays, none has been reliably documented. Nevertheless, it has been suggested that the original 1930s observations of these birds flycatching from a high perch, and subsequently flying between perches about 30-90 m apart, may have been of a type of display perhaps similar to those of other African eurylaimids. The flight of these individuals, observed in Zaire, was reported as being straight and level, with rapid but silent wingbeats. In the Ugandan population of Grauer's Broadbills, on the other hand, the flight was reported as slow and of a gliding nature, and even on short flights the birds rarely flapped the wings after becoming airborne, evidently preferring to glide. Such behavioural differences between these isolated populations complement apparent ecological differences (see Habitat). It is possible that detailed studies of these two populations, including comparisons of their behaviour, may indicate that, although morphologically similar, they are two incipient species.

Among the typical broadbills combined in the subfamily Eurylaiminae, information on general habits is limited almost entirely to breeding and foraging activities. Details of displays and associated behaviour are known for only two species. The courtship behaviour of the Black-and-yellow Broadbill in Peninsular Malaysia is outlined below (see Breeding). Otherwise, two pairs of Black-and-red Broadbills in Borneo which were disturbed while feeding on the ground flew into nearby trees, where they greeted each other with loud churring calls and melodious whistles, while simultaneously bowing at each other and depressing the tail under the perch. It seems possible that this could be a type of territorial display.

A detailed study of the members of this family in the wild would undoubtedly yield remarkable new information. An understanding of the display repertoires of all broadbill species would be of great value, particularly in helping to reveal the true relationships of the genera currently placed together in the subfamily Eurylaiminae (see Systematics). Territorial behaviour may, indeed, be widespread in the family. The possibility of lekking behaviour among the African broadbills and the green broadbills

is notable (see Breeding). All six members of those two subfamilies are sexually dichromatic, and available information suggests that the females undertake all or most of the breeding duties (see Breeding). The sexes of Grauer's Broadbill, on the other hand, are similar, and this suggests that the displays of that species may not necessarily be comparable with those of either the Smithornithinae or the Calyptomeninae.

Of the remaining eurylaimids, sexual dichromatism is most pronounced in *Eurylaimus* and *Sarcophanops* and is slight or absent in the other genera. The significance of this is unclear, but available information suggests that, for the species with similar sexes, both participate in breeding activities and, in the case of three of them, additional birds help at least with the construction of the nest (see Breeding).

## Voice

Broadbills are certainly not renowned for their songs, but the evidence indicates that all 15 species possess a range of vocalizations representing a repertoire covering breeding, foraging contact, alarm and other functions. A complex of vocalizations has been noted from a study of captive Green Broadbills, and this is supplemented by observations of wild-living broadbills. Although not a vocalization in the strict sense, the mechanical trilling and buzzing produced by the emarginated outer primary is a characteristic of aerial displays and other behaviour of the African genus *Smithornis*. These distinctive and far-carrying notes, long believed to be vocal sounds, are not known to be made by any of the Asian broadbills, but the asities of Madagascar produce similar mechanical sounds.

The African Broadbill has a weak, plaintive whistle sounding like "huiiii" and a soft "twee-uu", as well as a quiet mewing call. These seem to serve various functions, such as contact, alarm and distress, and are also used in courtship. Similar notes are uttered by its two congeners. In addition, the Rufous-sided Broadbill has been reported as combining the "huiiii" call with other rhythmic notes during courtship to produce a simple, very basic song.

The voices of those three broadbills are generally weak when contrasted with the noise produced by the outer primary feathers during display-flights. The pitch of these mechanical sounds varies

Most broadbill species are monogamous. Both adults take equal shares in nest construction, a process which requires the collection and transport of a considerable amount of nesting material, often contributed in rather small portions, as demonstrated by these **Black-and-red Broadbills**. Incubation duties and care of the young are probably also shared between the two parents. Little is known about territoriality in broadbills, and most pairs seem to range widely, occasionally overlapping into the ranges of their neighbours.

[*Cymbirhynchus macrorhynchos macrorhynchos*, Sukau, Sabah, Borneo. Photo: Günter Ziesler]

according to species, being lowest in the African Broadbill and highest in the Rufous-sided Broadbill. Within the African Broadbill, in particular, there is some apparent geographical variation in these sounds, but further study is required to determine the significance, if any, of these differences.

Mechanical sounds made by displaying African Broadbills are loud, and have been likened to the fast rattle sound produced by pinging the free end of a wooden ruler which has been clamped across the edge of a wooden table. After beginning suddenly, the sound slows, before accelerating and then ceasing abruptly. It is a very fast, staccato, whistle-like trill about 0.7 seconds long, and has been shown to consist of four to six notes in 0.25 seconds followed immediately by 15 notes in 0.5 seconds. The transcription of this noise has been expressed variously as "tttt-rrrrrrrrrr", "kerrrrr", "purrup", "pr-r-r-r-rrrrrrup", "krrrrrrrooo", or "brrrrup". It is interesting to note that this mechanical noise, which has a distinct buzzing quality when heard at close quarters, appears to change with increasing distance, so that, when heard from about 60 m away, it seems to be less mechanical and more musical.

The mechanical sounds of the African and the Rufous-sided Broadbills have been compared to amplified frog croaks, suggesting the possibility of convergent acoustic design, perhaps providing some protection against predators. In areas where these two species co-exist with Grauer's Broadbills, this amplified communication is also considered to give the *Smithornis* broadbills a competitive advantage.

Experiments by R. J. Dowsett and F. Dowsett-Lemaire, using playback of tape recordings, have demonstrated the closer interrelationship of the African and Grey-headed Broadbills. Both species react strongly to playback of each other's mechanically produced trills, while the clearly higher pitch of the Rufous-sided Broadbill's trill was confirmed when that species' two congeners did not respond to its tape playback. As a result, the authors suggest that, where the African and the Grey-headed Broadbills come into contact, some competition must be involved, despite differences in their habitat preferences, and that, in forest areas with many clearings, it is not clear which of the two the observer should expect to find.

In addition to these wing noises, the African Broadbill produces a loud klaxon-like noise when it hangs from a perch during courtship displays (see Breeding). This sound, too, is thought to be mechanical in origin.

The only other Afrotropical eurylaimid, Grauer's Broadbill, has a feeble "tsi-tsi" or "cree-cree" call which is rapidly repeated three to eight times. This vocalization, which may serve as a contact call, has been likened to that of the Oriole Finch (*Linurgus olivaceus*). In Uganda, this broadbill also emits a high-pitched, monosyllabic "prrrp". It is thought that a very high-pitched, protracted bell-like ringing, recorded in association with breeding, may have been mechanically produced, because it was noted to start when the bird flew and to stop when it landed. This could be significant in determining the kinds of displays which these broadbills may have, particularly if competition with other Afrotropical eurylaimids is involved.

Most of the eleven Asian members of the family are more vocal than their African relatives. Their calls encompass a variety of trills, whistles, squeaks and screams, depending on the species, and several of these eurylaimids have a fairly wide repertoire at their disposal. The most characteristic call of the Green Broadbill is a soft "toi" note repeated at increasing speed to become an upward-inflected trill. This has a distinctive bubbling quality, as do most other calls uttered by this species. The trill is sometimes preceded by a shorter frog-like rattle, which is sometimes given on its own as, probably, a contact call. Soft, mournful whistles, likened to the notes given by green pigeons (*Treron*), as well as a loud "oik", are commonly uttered in the vicinity of food sources. Captives also give variations of the typical bubbling trill in which the first syllable is higher and faster, these versions possibly functioning as both contact and alarm calls, and during display they utter a short series of "goik" notes each of which is accompanied by a bob of the head. A miscellany of cackles, wheezes and whines has also been noted from captive males, as has a "doy-doy-doy-ee-oh" phrase. The latter is believed to be a courtship song, and what seems to be a female version of it is much quieter, with the notes more like "oo" or "ho" and run together more rapidly.

Although it can be quiet for long periods, Whitehead's Broadbill can at other times be the noisiest of the *Calypomena* green broadbills. Its characteristic calls are snoring, grinding or wheezing noises, such as "toc-trrrr", "teek-waaaarrrr" or "chek, rrrrr-trrrr". A variation of these vocalizations, given by three or four males sitting together, was transcribed by the observer as "kerrrrrr" or "kh-khrrrrrr". Rather different notes, reminiscent of those of a woodpecker (Picidae), include a staccato "eek-eek-eek", a short, harsh "tzip" followed by a coarse rattle up to three

**Black-and-red Broadbills.**

like all members of the family, construct a woven, globular hanging nest with a side entrance; the entrance is sometimes disguised with a porch. Nest construction can take up to seven weeks. Whilst the nests are large, the actual nest cavity itself is small, and the head of the incubating bird can usually be seen protruding from the entrance of the nest. Nests are suspended at various heights usually from the fine outer branches of trees, and they commonly hang out over open areas, including water or even roads. Placing nests in exposed situations like this secures them from predatory mammals and reptiles, but it does expose them to damage by strong winds or even flooding. A study of 17 Black-and-red Broadbill nests in Malaysia revealed that six were destroyed before the young reached fledging.

[*Cymbirhynchus macrorhynchos macrorhynchos*, Sukau, Sabah, Borneo.  
Photo: Günter Ziesler]

The **Dusky Broadbill** is a very sociable species. Groups of up to 20 birds sometimes occur, and all group members may engage in building a single nest, as exemplified by this individual that has collected some nesting material. Whether these helpers go on to help with other aspects of the breeding cycle is for the present unclear, and more studies are required. In recent times it has become increasingly clear that co-operative breeding is a strategy favoured by a considerable number of tropical bird species.

[*Corydon sumatranus sumatranus*,  
Panti Forest Reserve,  
Malaysia.  
Photo: Ong Kiem Sian]

seconds long, and, in flight, a rapid phrase of harsh notes. A variety of other calls, ranging from chatters to hissing and wheezing noises, has also been documented for this eurylaimid, along with harsh calls like those of a jay (*Corvidae*), shrill notes, and a trogon-like "go-up" which, if imitated, may attract the species. By contrast, the only call recorded for Hose's Broadbill is a soft cooing, as if from a dove (*Columbidae*), and uttered in conjunction with head-bobbing and bowing actions.

Like the previous two species, the Black-and-red Broadbill is often silent and unobtrusive. Its principal vocalizations are a monotonous and repetitive "tyook", an accelerating series of "pamk" notes, and a rising trill. The last is not unlike a trill emitted by the *Eurylaimus* broadbills, but is slower, softer and shorter. The Black-and-red Broadbill's repertoire also includes grating notes reminiscent of a cicada (*Cicadidae*), short rasps, a hoarse, twanging "cow", a hoarse and grumbling "ka-ka-kraaar-kraaar" descending in pitch, loud churring calls, melodious whistles and, extraordinarily, a snarl that has been compared to that of a puma (*Felis concolor*) at bay. This species' calls are generally quieter than those of other Asian broadbills.

Flocks of Long-tailed Broadbills, on the other hand, are usually noisy, and are often first detected by their loud calls. Typical of these are a series of loud, sharp, descending whistles repeated five to eight times at increasing speed, usually uttered in flight or when about to fly. This whistle has been likened to one given by the Dusky Broadbill, but it is slower and more downward-inflected. A single, sharp whistle, "tseeay" or "seweet", and a rasping "psweep" are uttered intermittently and may be contact or alarm calls, but this species is otherwise relatively silent when engaged in feeding.

In rather stark contrast to the Long-tailed Broadbill, the Silver-breasted Broadbill is normally silent, being most vocal when near the nest. A mournful "ki-uu", likened to the sound from a rusty hinge, is its most typical call. Otherwise, a "pri-ip" serves as contact, while what is probably an alarm call, given in flight or when perched, is a thin, grating, insect-like trill of about six notes.

Loud, cicada-like trills are characteristic vocalizations of the two *Eurylaimus* species. That of the Banded Broadbill is immediately preceded by a brief, sharp whistle, the trill itself being five to six seconds long, increasing in tempo and rising in pitch, with the

final two or three notes dropping in pitch and dying away. This call frequently becomes a duet, as one bird starts up shortly after the first. In some cases, this trill prompts several individuals to call in turn, until a dozen individuals can be trilling, with the notes carrying a long distance. The Black-and-yellow Broadbill's trill is similar to that of its congener but about twice as long, and without the introductory whistle. It begins with some slower-paced, sharp, downslurred notes, but gradually speeds up to end as a quivering trill which terminates abruptly, rather than fading away. Pair-members call alternately, but with the second individual starting before the first has finished, and during bouts of calling one may emit a plaintive, shrill "peep". Various other calls shared by the two species are a single guttural roll and a descending squeak, and a "kor kor kor" given by males at the nest. It has also been pointed out that both species respond vocally to sudden noises such as thunder, a falling tree or the slamming of a car door, but they exhibit a poor response to tape playback.

*Sarcophanops* wattled broadbills, confined to the Philippine forests, appear to call only rarely. The Visayan Wattled Broadbill very occasionally emits an insect-like "tik, tik, t-t-t-t-t-t-t", usually repeated once after an interval of two to three seconds. Although this is very like a *Eurylaimus* vocalization, a similar call is given also by the sympatric Blue Fantail (*Rhipidura superciliaris*). Indeed, the latter's call could easily be mistaken for that of a wattled broadbill. A short, quiet whistle at medium pitch, heard on Bohol, may be a contact call. Although the Mindanao Wattled Broadbill is likely to have a similar repertoire, the only vocalization recorded for it so far is a plaintive whistle, which is probably similar to the presumed contact call of its congener. Wattled broadbills are reported to respond to imitations of the whistled call. Otherwise, perched individuals make loud snapping sounds with the bill, and the wings produce a whirring sound in flight.

Unlike the two Philippine species, the highly social Dusky Broadbill is often very vocal, although it also perches quietly for lengthy periods during the day. Group-members utter a distinctive series of six to eight screaming notes on an ascending scale, "hi-ky-ui, ky-ui, ky-ui", with the "ky" stressed, and the final notes sounding more like "ki-ip". Groups of these birds high in the canopy are usually first detected by these calls. In addition, a shrill, thin, descending "psseoo" and a high-pitched sharp "tsiu"

As in the cases of the other broadbills, the nest of the **Black-and-yellow Broadbill** is usually suspended from a branch some 5-19 m above the ground so that it hangs over an open area. This species has a large, untidy, pear-shaped nest made of twigs and looped grasses, like the long streamers carried by this individual; the nest is typically adorned with lichens. Black-and-yellow Broadbills also seem inclined to enlist additional help with security, for many nests are situated in close proximity to those of wasps and bees.

[*Eurlaimus ochromalus*,  
Panti Forest Reserve,  
Malaysia.  
Photo: Morten Strange]

are commonly heard. Other vocalizations of this large broadbill include a whistled "pee-u" or quavering "ch whit" in flight, a "pepepepepe" given near the nest, and an accelerating series of up to seven "chwoo" or "phwoo" notes. A loud croak and a rattling laugh have also been heard.

### Food and Feeding

Typical broadbills are insectivorous and carnivorous birds, having the broad, hook-tipped bill and wide gape that are required for such a diet. A few species also take fruit and other plant matter as a very peripheral component of their food, although these non-animal items are possibly of local importance, as for Banded Broadbills in Sumatra and Java. The green broadbills in the genus *Calyptomena*, on the other hand, have become specialist frugivores, with a reduced bill size but retaining the wide gape. Notwithstanding this specialization, green broadbills still occasionally include insects in their diet, perhaps opportunistically, but particularly during the breeding period, when a protein-rich diet is beneficial for feeding the young. The least specialized eurlaimid appears to be Grauer's Broadbill, which, according to the available evidence, seems to mix insectivory and frugivory as a normal foraging strategy, although frugivory may be more usual.

The diets of the insectivorous and carnivorous broadbills have not been studied in detail. Analyses of stomach contents, combined with field observations, indicate that insects comprise the bulk of the food consumed. Orthopterans, beetles, both heteropteran and homopteran bugs, and Hymenoptera, as well as their larvae and eggs, are the most frequently recorded items. Small invertebrates, such as spiders, millipedes (Diplopoda), snails and small crustaceans, have also been noted, as well as small vertebrates such as tree-frogs and lizards, and once even a small fish. The evidence suggests that these broadbills, while demonstrating preferences for certain prey items, are basically opportunists, and that in the case of the larger species, in particular, any small animal is likely to be taken. The Black-and-red Broadbill may have a broader dietary range, as it usually forages near water and also occasionally takes small fruits and other plant material, such as leaves. Banded Broadbills in Sumatra and Java

occasionally take fruits, and Black-and-yellow Broadbills sometimes feed on small berries.

All of these species combine aerial sallying and foliage-gleaning in their feeding strategies. They also take prey items while in flight by snatching them off leaves and branches. Foraging is usually carried out in the middle level of the forest, but these broadbills will occasionally descend to the ground layer or extend into the tree canopy in search of food. The Dusky Broadbill appears to be the only eurlaimid with a distinct preference for the upper canopy of the forest, but it will also forage at other levels. Most species forage singly or in pairs, but several, such as the Long-tailed and Silver-breasted Broadbills, form loose feeding flocks outside the breeding season, while the Dusky Broadbill is usually found in small groups (see General Habits). As mentioned previously (see General Habits), the majority of these non-frugivorous eurlaimids have been observed to join mixed-species foraging flocks, and all probably do so at various times.

Grauer's Broadbill seems to be primarily a frugivore. Records of stomach contents have revealed that, whereas some individuals have largely consumed fruits and flower buds, others have also taken insects and, in one case, even a snail. While evidently preferring to eat berries and small fruits, this species has also been observed to take insects in flycatcher-like sallies and by gleaning. It forages singly and in small flocks, with an apparent preference for lower levels, but also extending up into the forest canopy. It also joins mixed-species feeding flocks.

The *Calyptomena* green broadbills are true fruit specialists. Nevertheless, they also catch insects, such as emergent termites (Isoptera), in opportunistic fashion, particularly as a means of supplementing the diet of nestlings. The best-known of the three species, the Green Broadbill, has a preference for figs (*Ficus*), but it will also take any fruits with large seeds, including arillate fruits rich in lipids, such as those of *Eugenia*, *Horsfieldia* and *Knema*, as well as the large fruits of understorey palms and the hard, oily fruits of *Canarium*. Perhaps somewhat surprisingly, Green Broadbills also accept the much smaller fruits, less than 21 mm across, of trees of the families Meliaceae and Myristicaceae (nutmeg). At one study site in Peninsular Malaysia, this species was recorded as feeding on the variably coloured fruits of 21 species of fig; the smallest of these fruits measured 5.4 × 5.9 mm, but the size of fruits consumed ranged up to 32.4 × 27.4 mm. From a brief

radio-tracking study, it was found that two tagged Green Broadbills spent most of their foraging time in or near fruiting fig trees.

The two other green broadbills share a similar preference in terms of the fruits and berries which they eat, and both also take insects on occasion, especially during the period when they are feeding young. One interesting record involved a Whitehead's Broadbill, which was watched as it captured moths attracted to streetlights. Hose's Broadbill also takes leaf buds.

Unlike the frugivorous Asian barbets (*Megalaima*), the green broadbills do not possess sharp cutting edges on the bill. As a consequence, they are unable to mandibulate fruits and must, therefore, swallow them whole, however big they may be. Seeds measuring up to  $24.2 \times 16.2$  mm have been regurgitated by Green Broadbills.

Green Broadbills usually forage and feed in pairs or in small, sometimes widely dispersed groups, displaying a preference for the lower and middle levels of the forest but also briefly entering the canopies of fruiting trees. The fruit is usually plucked from the tree during short flights, but fallen fruit may, exceptionally, be picked up from the ground. Similarly, Hose's Broadbill forages in pairs and small groups, usually at lower levels of the forest. Groups of both of those species sometimes congregate to feed in the same fruiting trees. Whitehead's Broadbill is often solitary and rather shy, but small noisy groups of this species will also gather together at or near fruiting trees, when its loud behaviour is very unlike that of its two congeners. Moreover, individuals within these noisy foraging parties will at times perch on vertical tree trunks, a type of behaviour which, together with certain of the species' calls (see Voice), have reminded some people of the behaviour of woodpeckers. Whitehead's Broadbill has also been seen in the large mixed foraging flocks that are characteristic of the montane forest in which it lives.

A frequently observed foraging strategy of eurylaimids is the characteristic "sit-and-wait" behaviour followed by brief sallies to seize prey, either on the wing or from nearby branches and leaves. It has been suggested that this capturing of prey in the manner of flycatchers is the most common feeding method, but this may be simply because broadbills are more visible during this activity. For several broadbill species gleanings may be more important, but insufficient data are available to determine such preferences. It is not only the insectivores among the family that practise the aerial snatching of food. The *Calypptomena* species also employ this method, seizing both fruit and insects while in flight.

The Eurylaimidae, with their short wings, are not noted for their flying abilities. They use rapid, whirring wingbeats, sometimes in an ungainly manner, in order to pursue their prey. It is not always obvious that any particular perch from which to sally has been preferentially selected, and observers often report that these birds invariably alight on a different branch after having caught their prey. When foraging along branches or among leaves or other clusters of vegetation, broadbills hop or climb, sometimes clinging to vertical surfaces such as the bark of tree trunks, but they do not walk. This may be due to the weak hallux and the partial fusion of the third and fourth toes (see Morphological Aspects), demonstrating a poor adaptation of the feet for perching and, therefore, for walking, especially on narrow branches.

## Breeding

Information on breeding, for the period from courtship activity and nest construction to the laying of eggs, is available to a greater or lesser extent for all eurylaimids. Nevertheless, for many members of the family, the amount of detail is very limited indeed, this being particularly applicable to the two *Sarcophanops* species in the Philippines and the single *Pseudocalypptomena* broadbill in the Afrotropics. Study of the Green Broadbill in captivity has produced a great amount of additional data, some of it confirming earlier speculation on incubation periods and the adults' care and feeding of the young. Combined with this, a few field observations made during the nesting and post-fledging periods help to fill the picture. Unfortunately, no complete study of the breeding of any of the 15 broadbill species in the wild has yet been carried out.

Scattered temporal data relating to specimens in breeding condition, nest-building, eggs, the feeding of young, and so on, have revealed two main themes. While broadbills prefer to nest in the drier months, other factors are involved, as the evidence suggests that breeding periods are extended and can cover all or most months of the year. In the eastern and southern parts of Africa, wetter periods may be preferred. In South-east Asia, the variations from north to south in peak breeding periods coincide with the monsoon seasons. In most cases, this allows breeding in the drier months, with the onset of the rains providing the increased food resources required to feed the young. Even in such conditions, breeding periods can be extensive. For example, breeding records of the Dusky Broadbill extend over ten months, and, although they follow the monsoon pattern in the north of the species' range, populations living farther south commence nesting in the wetter months.

Although the breeding seasons of most eurylaimids are greatly protracted, little is known about the frequency of nesting by broadbills. The Long-tailed Broadbill will raise a second brood in a single season only if the first brood has been lost, and the Silver-breasted Broadbill, if it loses its nest, will start a second nest near the site of the original one. Green Broadbills will replace lost clutches, and it seems likely that other eurylaimids will also do so.

So far as is known, the broadbills are generally monogamous. Although confirmation is lacking, there is some evidence of possible polygyny by the green broadbills in Asia and the *Smithornis* species in the Afrotropics. Two male Green Broadbills observed in the wild performed what seemed to be a ritualized display, lasting about five minutes. The two were perched approximately 1.2-2.5 m apart on small horizontal branches up to 2.5 m above the ground, from where they uttered a continuous low "quit-quit-quit". These calls were accompanied by a quick up-and-down flicking of the head and a rapid flapping of the half-opened wings. During the display, the males changed positions, alternating between facing each other and perching back to back. The elaborate nature of such displays suggests that they may be performed in the context of a social gathering, such as a male lek, and that the green broadbills may be polygynous. This theory is supported by the notable sexual dichromatism of the *Calypptomena* species, the fact that the ornamental tuft is more prominent on the male, and that it is apparently only the female that is involved in building the nest, incubation of the eggs and raising the young.

On Mount Kupé, in Cameroon, a group of Grey-headed Broadbills was observed for five to ten minutes in fairly open forest. At least four birds were present, two of them males, with one female and another unsexed individual, the gathering resembling a lek. The two males displayed from a low horizontal branch over a gradual incline, with the female watching from a slightly higher perch. The males took it in turns to fly in a tight circle, returning to the branch in rapid succession, this display being accompanied by a mechanical trilling (see Voice); the white feather bases of the lower back were conspicuous throughout the performances. When perched, the males also swivelled with the throat puffed out, while drooping the wings so as to highlight yet again the white of the lower back. They also jumped up and down, sometimes doing this alternately in a way which was considered to be similar to that of displaying manakins in the Neotropics.

Broadbills usually suspend their woven, pear-shaped nests from the tips of tree branches or similar conspicuous sites. These characteristic nests can be suspended over forest clearings, but several species commonly locate them above rivers, streams or similar places, and such nests can occasionally be found above roads, paths or ditches, or in mangroves. The widest diversity of nest-sites has been recorded for the Black-and-red Broadbill, which occasionally makes use of such unusual sites as overhead wires and even poles emerging from water. Two attempts made by this species to suspend a nest from telephone wires were unsuccessful because of strong winds, and such sites as poles standing in water are at risk of flooding. Nest records from Peninsular Malaysia found that, of 17 Black-and-red Broadbill nests, six were destroyed before breeding was completed.

The location of the nest varies from 1 m to 30 m above the ground, but is usually in the range of 3-10 m. Afrotropical

This pair, or group, of **Dusky Broadbills** have suspended their nest securely from the tip of a rattan palm tendril. Such tendrils feature an array of medieval-looking thorns, which should effectively deter most predators from approaching the nest from above. Hanging the nest out in the open ensures that the nest cannot be reached by any other "solid" routes. The nest is a large, bulky, domed structure, generally about 30 cm in diameter and some 2 m or more in length. The laborious process of nest construction involves weaving together an array of plant material such as grass, twigs, leaves, moss and roots to form the main structure. The interior is lined with green leaves, grassy fibres and hair-like roots. The final stage involves the addition of adornments to the nest and building the long, dangling tail that is characteristic of so many broadbill nests. Typically, nests are adorned with leaves, spiders' egg-bags, cocoons and caterpillar excreta, all fixed in place using cobwebs. Nest construction time varies within the family from 5 days to 7 weeks. The end result is an effectively camouflaged nest that is well out of the reach of most mammalian and reptilian predators.

#### Silver-breasted

**Broadbills** are sociable birds and regularly enlist helpers at the nest. Members of the group assist in nest construction and they sometimes also help with both incubation and the rearing of the young. Nest construction takes 5-10 days but adornments are commonly added for many days after the incubating birds have taken up occupancy. The nest of this species tends to look rather neater than those of many other members of the family.

broadbills usually locate their nest 1-3 m above the ground, though at times very much higher, and normally away from open areas. In some cases, nests are hidden within the canopy foliage, as recorded for the Black-and-yellow Broadbill. In Borneo, the latter species often places its nest near bees' nests or in thorny trees, while the Banded Broadbill has also been seen to nest near a bees' nest, and the Black-and-red Broadbill near a wasp nest.

The practice of placing nests in conspicuous but apparently inaccessible sites is obviously an adaptation providing effective protection against nest predation by mammals and reptiles. The renowned ornithologist E. C. Stuart Baker once observed a rhesus macaque (*Macaca mulatta*) attempting to stretch over to a Long-tailed Broadbill's nest, but, just when the nest was nearly in its grasp, it slipped and fell into the stream below.

Eurylaimid nests have been variously described as resembling a pear, a gourd, a bag, a purse, a ball and a dome. The Green Broadbill builds its gourd-shaped nest by attaching it across branches, rather than suspending it from a branch tip, and this species is otherwise notable for the small size of its nest-cavity, requiring the female to sit with her head protruding outside. The other *Calypomena* species build an apparently similar structure, although possibly with a bigger nest-cavity, but they are reported to suspend the nest from a branch tip. All nests are tightly woven from a variety of materials, including grass strips, vines, small sticks, bark strands, leaf fibres, creepers, rootlets, fungal hyphae and moss, while the nest-chamber is lined with softer material, such as leaves, grassy fibres and hair-like roots. One nest of the Grey-headed Broadbill was constructed entirely from black fungal fibres, while others were built predominantly with green moss. The entrance hole, at the side, is normally more or less concealed by a "porch" or step. Some nests have been described as untidy, but this is usually the consequence of the amount of nest decoration that is added, including the drooping "tail", which can be relatively quite long. Even though nests are quite frequently placed in conspicuous locations, the nest decoration provides effective camouflage among vegetation hanging from trees. Decorative materials include lichen, green moss, egg cases of spiders, caterpillar excreta and cocoons, all held together by cobwebs, plant stems and tendrils, with the biggest "tails" attached to the most decorated nests. One Dusky Broadbill nest was decorated with the runners of an epiphyte, providing a covering of small living, green leaves.

Few precise data are available on the time taken to construct the nest. In captivity, a female Green Broadbill completed her nest in five days, the male taking no part in the work. In the case of the Silver-breasted Broadbill and the Long-tailed Broadbill, both sexes co-operate in building the nest, sometimes assisted by helpers. For the former, nest construction has been estimated to take five to ten days, whereas the latter species can take about three weeks to complete the task. One pair of Black-and-red Broadbills was thought to have required seven weeks to construct its nest, even though both partners participated in the work; this particular nest, however, was slung beneath telephone wires, and high winds may have been a problem for the birds. At another nest of this species, during the later stages of construction, an adult was seen to remain inside the nest-chamber while its partner gathered material; in this instance, it seems possible that the broadbill inside the nest was engaged in shaping and tidying the inner cavity. Long-tailed Broadbills are known to reuse nests over several seasons.

Three broadbill species are known to breed with the assistance of helpers at the nest. A pair of Long-tailed Broadbills may be assisted in the construction of the nest by up to five helpers, which possibly also take part in the incubating of the eggs and the feeding of the young. A similar situation applies to the Silver-breasted Broadbill, although the number of potential helpers is uncertain. In the gregarious Dusky Broadbill, the whole group of up to ten or more birds takes part in nest construction, but it is not clear if all individuals also assist with incubation and brood-feeding.

Observations on captive Green Broadbills have revealed some intriguing aspects of the species' breeding behaviour. The female mentioned two paragraphs above, after having spent five days in building her nest, proceeded more or less to ignore it for two days, during which time the male displayed vigorously to her with deep head-bobbing movements while ruffling his head feathers. Both then perched across a branch, making similar deep head-bobbing movements; they frequently perched so close together that they almost touched one another, and each one ruffled the back feathers. These displays continued for three days, when the male then fed regurgitated food to his mate, this being followed by copulation, with the first egg laid three days later. The deep head-bobbing has been seen to be performed by a number of captive Green Broadbills in different collections. In

The nest of the **African Broadbill** is a typically untidy bag suspended from a horizontal branch roughly 1-2.5 m above the ground in dense, well-shaded forest understorey. Nest size varies considerably from about 20 cm to 100 cm depending on the length of the dangling "tail".

Two or three small, glossy white eggs are laid, each being rather elongated with a point at one end. Only females have been recorded incubating. In fact, the breeding biology of this widespread and locally common species remains surprisingly poorly known, but it is thought to be monogamous and territorial.

[*Smithornis capensis capensis*, South Africa.

Photo: E. & D. Hosking/FLPA]

some cases, a captive male has used a particular set perch and, when approaching such a perch, the male has sometimes adopted a slow, butterfly-like flight with the body held upright; the same flight is occasionally used when approaching the female.

In another display, the male, usually when close to the female, assumes a hunched, "neckless", posture, crouching very low, and raises the distinctive tuft of loreal feathers to reveal the tiny patches of bright yellow and black feathers just in front of the eyes. During this display, he repeatedly flashes the wings and rapidly opens the bill to the fullest extent, exposing the orange-pink mouth. A captive female has been seen to respond to the gaping male by crouching on her perch, with the tail held horizontally, the half-opened wings slightly shivering, and the body feathers fluffed up, whereupon the male, with fluttering wings, mounted her and copulated for three or four seconds before hopping off and perching nearby.

As an immediate precursor to the initial crouching and wing-flashing display, the male usually flies at high speed in a very regular pattern around the aviary. This ricocheting flight (see also General Habits) may also be followed by courtship feeding, in which the male regurgitates a berry and offers it to the female. This is sometimes repeated up to four times, with the female accepting at least three of the berries. The perched female will at times solicit courtship feeding by fluffing up the body feathers and shivering, with low-intensity head-bobbing; her mate's normal response to this is to offer food, and in every observed case the female accepted this.

An apparent courtship display by the African Broadbill was observed in September in Mozambique. Two individuals of this species perched about 45 cm apart on a low horizontal branch. Both performed wing-flicking, before swinging downwards and hanging from the branch; while thus suspended, and still wing-flicking, they made loud klaxon-like sounds, evidently produced by the outer primaries, for a period of half a minute or so, after which they righted themselves. The two then flew off and perched separately, about 100 m apart.

Despite its taxonomically close, congeneric relationship to the African Broadbill, the Rufous-sided Broadbill has a courtship display which is very different and which usually occurs between display-flights. The male approaches a female and, with his head turned away from her, utters several "huiiii" calls. Holding the body horizontally, with the legs bent and the bill pointing upwards, he then puffs out his plumage, thereby making the white mantle and the orange breast-side patches conspicuous. With the wings drooping, he opens and closes them in a rhythmic fashion, and from time to time flicks them high above the mantle. The display is terminated by the male making a series of short, excited jumps in front of the female, these being accompanied by a song-like sequence of rhythmic calls.

In the forests of Peninsular Malaysia, the courtship and mating behaviour of the Black-and-yellow Broadbill has been observed in February. This was witnessed in the early afternoon, on a day when the species had been heard calling frequently in the morning. A calling male was watched as it alighted on a small horizontal branch close to the trunk of the tree, and just above another branch on which a silent female was perched. The male proceeded to extend his wings slowly sideways, horizontally and almost to their full length, where he then held them while moving his tail from side to side in an exaggerated manner; at the same time, the female shivered her half-opened wings. After a brief period, the male flew down and copulation took place, but both broadbills then flew to another perch about 3 m away and resumed copulation. After this, the male moved about 30 m from his mate and slowly raised and lowered his wings for a short while, before the two flew away.

The eggs of the *Smithornis* broadbills are rather elongated, with a point at one end, glossy white in colour and rather small. Those of the African Broadbill measure no more than 19.24.5 × 14.5-16 mm. *Calyptomena* eggs are similar in shape and colour, though generally more creamy-tinted, but are distinctly larger, with maximum dimensions of 36.8 × 25 mm.

Black-and-red Broadbill eggs are dull, with no gloss, and vary in shape, size and colour: they are oval, either broad and short or long and blunt, measuring 25.29.3 × 18.2-20.7 mm, and occur in

**Female Green Broadbills** take sole responsibility for nest construction, incubation and brood-rearing. The nest is a relatively simple structure; indeed, in captivity one nest took just five days to construct! The nest is hung from a horizontal branch low in the understorey, as is the case with *Smithornis* and *Serilophus* broadbills. It usually remains unadorned with the sort of camouflage material that is typical of many broadbill nests. One to three elongated white eggs are laid, and incubation takes 17-18 days. After hatching, the young remain in the nest being fed by the female for a further 22-23 days before fledging. Rather oddly, males possibly remain in close attendance, as they have been observed undertaking injury-feigning displays which may serve to lure potential predators away from nests.

**Long-tailed Broadbills** lay 4-8 eggs that have an elongated oval shape and are slightly compressed at the smaller end. They average 27.4 x 19.4 mm in size. Egg colour is variable, ranging from pure white to deep pink marked with blotches of shades of pink, red and reddish-brown, with smaller lilac-grey markings; all markings are usually denser at the broader end. Incubation and brood-rearing in this species may be shared between the parents and helpers from the same social group or flock.

[*Psarisomus dalhousiae*.  
Photo: Larry Tackett/DRK]

three basic colour types. The commonest type is pale pink and covered all over with dull pale reddish-brown freckles, which sometimes form ill-defined blotches; others are more or less white with claret or purplish-red marks; the third type is also white, but with fewer and darker, almost purple-black, markings. The eggs of Long-tailed Broadbills, which are similar in size to those of the preceding species, have a rather elongate oval shape, slightly compressed at the smaller end. Their colour ranges from pure white and glossy to deep pink and more or less unglossed, the latter type having pink, red and reddish-brown blotches, with smaller lilac-grey markings that are usually most dense at the broader end. The Silver-breasted Broadbill's eggs are normally a short, blunt oval, rarely somewhat elongate, but not pointed, and they measure 22.2-26.7 x 16.2-18.1 mm; those of the nominate subspecies are glossy white, faintly cream-tinged, with sparse tiny reddish-purple speckles, which are denser at the broader end, whereas those of the Himalayan race *rubropygius* are pinker and have larger spots.

*Eurylaimus* broadbills lay smooth, faintly glossy eggs of a narrow, fairly regular oval shape. Those of Banded Broadbills from west Java are off-white to greyish-cream in colour, or occasionally pinkish-clay, and are well covered with irregular small markings, mostly dull rusty-brown but some lavender-grey, especially at the blunt end; the dimensions are 27.6-31.5 x 20.1-22.2 mm. Eggs from elsewhere in the species' range are white to pale creamy, with deep purple, dark reddish-brown or, occasionally, pale reddish-lavender spots and freckles; they are not unlike the eggs of some drongos (*Dicruridae*). Ten eggs collected in places away from Java were smaller, measuring 26.1-28 x 17.1-20 mm. The few reported eggs of the Black-and-yellow Broadbills are smaller still, at 23.5 x 16.5-17 mm; they are mushroom-pink and copiously covered with brown and purple-brown flecks, these marks forming a dark ring where concentrated around the broader end. They have also been described as being identical to the eggs of the Banded Broadbill.

Nothing is known about the eggs of the two wattled broadbills in the Philippines, nor of those of Grauer's Broadbill. Indeed, the breeding biology of all three species remains to be discovered. Finally, the Dusky Broadbill's egg is a broad, almost elliptical oval, smooth but glossless. Its ground colour varies from pale reddish to dull cream, normally with numerous reddish-brown freckles that may almost obscure the ground colour, though two

had larger blotches and underlying marks of pale lavender; the eggs measure 27.2-34.9 x 20-24 mm.

Clutch sizes of the Eurylaimidae range from one to eight eggs, but in the great majority of cases only two or three young are raised in any single breeding attempt. In a captive pair of Green Broadbills, the female laid the first egg three days after copulation, with the second following three days later, but, as she failed to incubate these eggs properly, they were removed. Three weeks later, two more eggs were laid, with an interval of two days between them. All observations of this species indicate that the female alone incubates, the period in captivity being recorded as 17-18 days; the young are fledged when 22-23 days old. Data on the incubation and fledging periods of other broadbills are virtually non-existent. The Long-tailed Broadbill has been said to incubate its eggs for more than 14 days, which seems quite likely to be the case.

Apart from the few instances already mentioned here, such as the Long-tailed and Silver-breasted Broadbills, which have helpers at the nest, and the co-operatively breeding Dusky Broadbill, the roles of the sexes in the various breeding duties are very poorly known. In the case of the Rufous-sided Broadbill, the female alone incubates but both sexes feed the chicks. The male Black-and-red Broadbill probably shares the task of incubation with his mate, but this remains to be fully confirmed.

A most intriguing injury-feigning display is sometimes performed by the male Green Broadbill in the wild. During this display, usually given near the ground and presumably near the pair's nest, the broadbill can appear to have become caught up in a spider's web or to be "stuck" to its perch, all the time screaming with wide-open bill and with frantic wing-flapping, and giving every impression of being wounded. If approached, the displaying bird flies a short distance to another perch and continues the performance.

Observations of Banded Broadbills in Borneo revealed a rather long period of post-fledging dependency. Even 13 weeks after fledging the young were still receiving 70-80% of their food intake from the parents, the proportion dropping to 20-30% at 20 weeks. Again in Borneo, a study of six Green Broadbill nests gave a success rate of 0.5 young fledging per pair.

Broadbills are probably the hosts of several species of parasitic cuckoo (*Cuculidae*), but little has been recorded on this subject. One nest of the African Broadbill in Zimbabwe contained

### Movements

Tropical forest birds are normally resident species which make only limited local movements, and the broadbills accord with this general pattern. There are a few instances in which wider movement has been noted, but this has generally been reported as being unusual, one example being that of Dusky Broadbills wandering to higher altitudes. Extremely dry conditions can cause birds to wander well outside their normal range. For example, in Borneo, during the severe drought conditions of 1997/98, a Whitehead's Broadbill, normally a montane bird, was found at an altitude of only about 75 m, in forest far from the mountains. This represents a very exceptional record, but it is nonetheless likely that other eurylaimid species could be affected in comparable ways by such extreme weather conditions.

In the Himalayan foothills, both the Long-tailed and the Silver-breasted Broadbills undertake seasonal altitudinal movements. With the arrival of winter, and a concomitant reduction in food resources as a result of the cold weather, these birds move to lower altitudes, even on to the nearby plains, returning to higher regions in the following spring. The extent of such movements by these species is poorly known. In the western parts of their ranges, both are now uncommon, scarce, rare or quite localized, and they have disappeared altogether from some regions. It is possible that populations normally favouring higher altitudes have been adversely affected by habitat changes in the lower-lying wintering areas.

The Green Broadbill is probably a locally nomadic bird in association with the seasonality of its preferred fruiting trees. A brief study of four radio-tracked individuals of this species indicated movements covering at least 2.5-6 ha per day, with one female ranging over about 13 ha in seven days and a male covering about 24 ha in six days. Movements of this kind may be more extensive if the available food resources are reduced in some

**Silver-breasted Broadbills** sometimes enlist helpers to assist in the business of rearing their young. A steady supply of invertebrate prey is required to raise the young to fledging, after which the hard work continues. The post-fledging dependency period appears to be long in broadbills. Observations of Banded Broadbills (*Eurylaimus javanicus*) in Borneo have demonstrated that even 13 weeks after fledging young birds were still receiving 70-80% of their food intake from the parent birds. Eventually, this proportion dropped to 10-20%, after 20 weeks.

[*Serilophus lunatus rothschildi*, Maxwell Hill, Malaysia. Photo: Ong Kiem Sian]

an egg which, from its size and appearance, was considered to have been laid probably by a Barred Long-tailed Cuckoo (*Cercococcyx montanus*). Eggs of unidentified cuckoo species have also been found in nests of the Silver-breasted Broadbill in Myanmar and Sumatra. Most reports of nest parasitism on eurylaimids, however, relate to the Black-and-yellow Broadbill in Peninsular Malaysia, from where separate records involve a pair of adults feeding a young Indian Cuckoo (*Cuculus micropterus*), adults feeding an unidentified cuckoo fledgling, and a nest containing an unidentified cuckoo egg.

In summary, broadbills, in common with many tropical birds, build camouflaged nests in situations designed to minimize predation, they produce usually small clutches and, where breeding seasons are protracted, they may produce multiple clutches, yet the survival rate of nestlings is apparently poor. Although most eurylaimids were in earlier times considered to be abundant, the implication appears to be that, in optimal circumstances, the replacement rate of individuals is sufficient to maintain population levels. What these levels require further investigation, as the few surveys which have been undertaken suggest that broadbills have a relatively low population density. While a study in Borneo found only Green Broadbills to be present at all sites in all survey periods, this may well be due to the greater mobility of frugivorous birds following the random fruiting of favoured food trees.

Ringling studies carried out in Peninsular Malaysia have indicated that in the wild the Green Broadbill can live for at least five years, and probably much longer. A captive Green Broadbill is known to have reached an age of at least 19 years. In addition, a Black-and-red Broadbill ringed as an adult in Malaysia was recaptured five years later, by which time it would have been at least six years old. It is likely that all broadbill species can be long-lived birds. Indeed, various long-term ringling projects around the world have revealed that small forest-dwelling birds can have a longer life expectancy than was formerly believed to be the case.

In general, it seems that broadbills seldom reuse nests in subsequent breeding seasons, although the Long-tailed Broadbill (*Psarisomus dalhousiae*) has been known to return to the same nest during several successive seasons. Perhaps further field observations will show this practice to be more widespread than is currently thought. In some cases, such well-built, relatively secure constructions may be taken over by other species for nesting. Here a Little Pied Flycatcher (*Ficedula westermanni*) has taken up residence in an old Silver-breasted Broadbill nest, whence the diminutive female flycatcher can be seen peering out.

[*Serilophus lunatus rothschildi* (nest), Fraser's Hill (1400 m), Malaysia. Photo: Morten Strange]

**Whitehead's Broadbill** is a restricted-range species found in a few montane areas in northern Borneo.

Although patchily distributed, it appears to be common in suitable habitat. Forest cover at higher altitudes in Borneo is still extensive and remains largely intact. For this combination of reasons, the species is considered secure for the time being.

[*Calypturnesia whiteheadi*, Borneo.

Photo: Roland Seitre/Bios]

regions. For example, four Green Broadbills netted in December 1968 at 1300 m on Fraser's Hill, in Peninsular Malaysia, were at least 400 m above their normal altitudinal limit in that part of their range.

For the family's two other frugivores, Hose's Broadbill and Whitehead's Broadbill, no details are available to indicate whether any movement takes place within their normal montane ranges. Further, the extent of the occurrence of Hose's Broadbills at lower elevations is unknown. In both cases, however, it seems possible that known gaps in their respective distributions, with the birds being absent from apparently suitable areas, may be due not simply to local absences of favoured food trees, but to an incomplete understanding of the movements of these broadbills. On the other hand, many birds inhabiting tropical forest have patchy distributions, and this may be the case for these two eurylaimids.

### Relationship with Man

Broadbills share a dependency on the forest environment not only with other animals, but also with the indigenous peoples who rely on this natural habitat for all their resources. Indirectly, this can be seen through the contribution made by the birds to the control of invertebrate populations and to the dispersal of tree seeds. Recent changes in human activity have resulted in an expansion in agriculture and other forms of land use, at the expense of the forested areas that are essential to the survival of the birds and other organisms.

Seed dispersal by frugivorous birds is known to play a significant role in the viability of populations of important food plants. The Green Broadbill, for example, feeds on a diversity of fruits, with a preference for figs (see Food and Feeding). Apparently, a more crucial role, and one in which its specialized wide gape is important, is that of the consumption of the large fruits of understorey palms and perhaps other important understorey plants. The long-term loss of these birds, or a severe reduction in their numbers, could prove to be detrimental to the survival of such plants, and this would have a reverberating impact on the ecology of the forest. One consequence may be the loss of plants used by humans for food or exploited in other ways.

A more direct relationship with man is evident when the birds themselves are considered as potential food resources. In the more remote regions of tropical Asia, broadbills, along with many other birds, are trapped for consumption as part of the diet of the local people. This kind of exploitation, however, is unlikely to have any significant adverse effects on the population levels of any

species, except where it is combined with habitat loss; this can be a very dangerous combination.

Several broadbills are known to turn up in cagebird markets in South-east Asia, as can virtually any bird species. A popular reason for keeping birds as pets is for the enjoyment of hearing their pleasant songs, but the eurylaimids, with their limited vocal abilities (see Voice), are not prized as songbirds. Perhaps their bright colours are an attraction. A more likely explanation for trapping and selling broadbills, however, is that these birds are eaten. It is not known if any species of eurylaimid offers any contribution to indigenous medicine, which is another major reason why tropical animals are captured.

The recent phenomenon of an expanding network of global birdwatchers has provided indirect benefits for tropical birds. Broadbills are one of many avian groups that are of particular interest to visiting ornithologists, who help to contribute to the economies of local human communities and, at the same time, offer long-term viability for the establishment and management of protected areas. There is great potential here for both the local people and the birds.

### Status and Conservation

Among threatened natural environments, tropical forest rates very highly, particularly because its continuing loss has been well documented and publicized. The destruction of tropical forest is also of great concern because it is well known that biodiversity is greatest by far in these regions, and there is still so much to be learnt about the plants and animals affected by the disappearance of this habitat. Broadbills provide an excellent illustration of this. All eurylaimids depend on forest. A few appear outside forested habitats for brief periods, or as part of their daily foraging strategies, but only if forest is present nearby. Only one, the African Broadbill, occurs widely outside tropical forest, but this species is also subject to habitat loss in those areas. As with most species inhabiting tropical forest, knowledge of these birds is limited.

A great deal was discovered about broadbills by ornithologists active in the period spanning roughly the 1870s to the 1940s. Additions to this knowledge base have come mostly through an increase in observations during the final two decades of the twentieth century. Much of this recent activity has focused on the monitoring of changes in distribution and status. While some additional insight has been gained into the habits and nesting

**The Black-and-yellow Broadbill** is currently listed as Near-threatened.

Like many broadbills, it depends on lowland rainforest, a beleaguered habitat. Broadbills show little ability to adapt to habitat degradation and disturbance, and local extinctions have occurred as a result of logging and other activities. Continued forest damage, together with an increased knowledge of the ecological requirements of lowland-forest broadbills, is sadly likely to push more broadbill species on to the lists of birds of conservation concern.

[*Eurylaimus ochromalus*. Photo: Cyril Laubscher]

*Hose's Broadbill* occurs in a few mountainous areas of northern Borneo. Listed as Near-threatened, this species' preference for forest on sub-montane slopes means that it is not immediately threatened, although these areas are increasingly being subjected to logging activities. This species is one of the least-known of all the broadbills.

VIREO]

activities of eurylaimids, particularly those of the rarer species, no broadbill has been studied comprehensively in the wild.

It is hoped such studies will be carried out before too long, but the overriding concern is the long-term survival and conservation of these birds. All species of broadbill are found in protected areas in some parts of their ranges, but too many populations remain under threat. Over their entire ranges, all members of the Eurylaimidae are now regarded as uncommon to rare, and, while some are locally common, this may be simply because they occur in forests that are yet to be exploited. The adaptability of these birds to forest degradation appears to be limited, and severe loss of habitat can lead to local extinctions.

The worst example of local extinctions concerns the island of Singapore, at the foot of the Malay Peninsula. At least five eurylaimid species once lived there. The last record of any one of them involved a sighting of the Green Broadbill in 1941, and that species probably disappeared soon after. It was claimed that two other species had survived until 1950, but both had actually disappeared by the 1940s at the latest, and probably well before then. Broadbill populations in Singapore were probably always small, and it is worth noting that there have been several other avian extinctions there, indeed well before the island became the extensively built-up environment that it is today.

Moreover, broadbills appear to be vulnerable on small islands in general. Several eurylaimids may have occurred on Pinang, off West Malaysia, but, if so, they disappeared long ago. Some persist on small islands in Indonesia and the Philippines, but recent records exist for only a few of these, such as the Black-and-yellow Broadbill on Pulau Laut, off south-east Borneo. In other instances, the Dusky Broadbill can no longer be seen on the south Thailand island of Phuket, and the Black-and-red Broadbill may already have gone from the Mergui Archipelago, in south Myanmar.

In the most recent catalogue of the world's threatened birds, published in 2000 by BirdLife International, three broadbills are listed as being threatened. These are Grauer's Broadbill and both Philippine species of wattled broadbill, all three of which are classified as Vulnerable. Of the remainder of the Eurylaimidae, it is pointed out that several others in South-east Asia are potentially threatened, a situation that applies to many tropical birds which are either wholly or mainly confined to

lowland forest. The book repeats a depressing message to justify this likelihood. In western Indonesia, for example, all lowland forest may have been destroyed by the year 2010, and a similar scenario is probably applicable elsewhere in South-east Asia. As a consequence, three eurylaimids are placed in the conservation category of Near-threatened. These are the Black-and-yellow Broadbill and two of the *Calyptomena* species, the Green Broadbill and Hose's Broadbill.

Compared with the situation in Asia, the prospects for the immediate future of the African fauna may not be quite so worrying. While it has been acknowledged that all remaining tropical forest in Africa is now part of logging concessions granted to various companies in different parts of the world, the circumstances in certain regions are perhaps not so desperate. In July 2001, for example, a German logging company announced that it had given up its lease on a 60-km<sup>2</sup> concession so that the area could be added to the Nouabale-Ndoki National Park. Moreover, while retaining leases on 8000 km<sup>2</sup> of forest elsewhere in the northern Congo, the company has also agreed to limit hunting by logging crews and to reduce damage incurred during timber-harvesting.

Grauer's Broadbill has a very restricted and fragmented range. Although it appears to be locally common, the area in which it occurs is under increasing pressure from commercial logging, mining, agriculture, hunting, and the political volatility of a region affected by the presence of thousands of human refugees from neighbouring regions. Its stronghold is thought to be the Bwindi-Impenetrable Forest National Park, in south-west Uganda. Otherwise, it occurs only in easternmost Zaire, where the Kahuzi-Biéga National Park, west of Lake Kivu, offers much suitable habitat for the species, but is under threat. The Itombwe Mountains, of vital importance for this broadbill and for many other remarkable species confined to this African escarpment, remain relatively intact, but they are not protected by any legislation.

Both of the Philippine wattled broadbills face the same threats of deforestation, mining activities, agricultural expansion, soil erosion and forest fires, a fate shared with many Philippine endemics. There are recent records of the Mindanao Wattled Broadbill from two protected areas, Mount Apo Natural Park and the island of Siargao; the species may also survive in the Mount Hilong-Hilong Watershed Reserve, Basilan National Biotic Area and Mount Matutum Forest Reserve, for the last of which the

status of national park has been proposed. The Visayan Wattled Broadbill occurs in only one protected area, the Rajah Sikatuna National Park, on Bohol, where it appears to be safe for the time being. These two species are the least-known of the Eurylaimidae, and information on their habitat requirements is essential for the drawing-up and promoting of further conservation plans. The Visayan Wattled Broadbill, for example, is considered to be a characteristic component of forested limestone outcrops, but it is more than likely that this is a relatively recent phenomenon, the result of a massive reduction in suitable areas of forest elsewhere within the species' range.

Some concern could be expressed for a number of broadbills which have not been listed as being at any current risk. The African Broadbill, for example, is now scarce and localized in the eastern and southern parts of its range, where it has either disappeared from a number of areas or become very rare. In West and Central Africa, this species and its two congeners are considered to be rare to locally common, but perhaps under-reported from many regions. This could be a reflection of the fact that surveys in several areas have suggested that their population densities are apparently low.

Over the wide ranges occupied by the Long-tailed and the Silver-breasted Broadbills, both have become uncommon to rare and local, and may even have disappeared from many areas. In some parts of South-east Asia, however, they appear still to be locally common. Apart from the pressures of habitat loss, both are known to turn up in cagebird markets, and trapping may be exerting undue pressure on many populations. These two broadbills are becoming rare and isolated in Indochina and very rare in China.

Of the remaining eurylaimids restricted to South-east Asia, all survive in greatly reduced numbers, and are now considered uncommon to scarce and local over the northern parts of their ranges. Broadbills living in montane forest are still relatively secure, although one of the two *Calypotomena* species that are found only in Borneo, Hose's Broadbill, is, as mentioned above, classed as Near-threatened. Of those found in lowland forest, most remain uncommon to locally common in the southern parts of their

ranges, but this habitat is seriously threatened in many areas and is likely to diminish markedly over the next decade or so. There is some evidence to indicate that broadbills will, to a limited degree, tolerate logged forest, but not where it has been severely degraded. The Black-and-red Broadbill occurs in a variety of forest types because of its preference for the proximity of water (see Habitat), but, while entering degraded areas, it requires the presence of scattered tall trees and it remains near rivers and streams. Although this species is still locally common in areas in which much of the forest is degraded, it has nevertheless also disappeared from other, apparently suitable habitats, as is the case in Sumatra.

The tolerance of forest birds towards the deterioration of their environment varies greatly. In the case of the broadbills, observations have demonstrated that several species are able to accept a small amount of disturbance and that some agricultural activity creates foraging opportunities for them. Severe degradation of forest, however, and in particular that resulting from commercial logging operations, invariably results in the decrease of populations. When regrowth takes place, broadbills will to some extent re-establish themselves in such areas, but at reduced numbers in the short to medium term. In one study, for example, the population of Green Broadbills remained at a low level even 22 years after recolonizing a previously degraded forest.

The success of BirdLife International in co-ordinating a database not only on threatened birds, but also on all birds of potential conservation concern, offers some hope for the future. The establishment of a network of protected areas through the Endemic Bird Areas assessment of remaining habitat, in combination with an expanding understanding of biodiversity as a concept and in conjunction with the input of sustainable-development programmes, appears to be having positive results.

Of all the many threats facing tropical birds such as the broadbills, the greatest must surely be that of the commercial logging of natural forest in so many regions of the world. Moreover, in combination with this activity, and frequently as a direct result of it, areas which were hitherto inaccessible are being opened up to other forms of exploitation such as legal and illegal mining, both of which are destructive in their own ways. Fire is also a significant threat, as demonstrated in recent years in Indonesia, where uncontrolled burning wiped out large areas of natural vegetation. It is well known that many of these fires were started deliberately as a means of clearing up the untidy aftermath of logging operations, in an attempt to "justify" logging as an acceptable activity. The truth is, in fact, that illegal logging imposes one of the most serious threats to the world's fauna and flora, having major impacts throughout the tropics.

The most recent major setback in efforts to protect the world's wildlife is associated with the political "war" on terrorism, started in September 2001. This could have indirect but severe consequences for conservation. In Indonesia, for example, threats made against foreigners as a protest against this war have caused a cessation of co-ordinated protected-area management programmes in the country. One can only hope that any such disastrous misunderstandings are short-lived.

While the future may seem a bleak one for tropical forests, especially those in lowland areas, the response of conservation bodies is very active. Indeed, there is a sufficient glimmer of hope that a system of protected areas, in particular, will ensure the survival of all tropical bird species, even if not all populations of them. If this proves to be the case for the broadbills, then it is possible that ornithologists will, at last, have the time and the opportunity to learn more about these fascinating birds.

Barker *et al.* (2001), Bates (1914), Bonaparte (1853), Clench (1992), Dekker & Dickinson (2000a), Dekker *et al.* (2000), Ericson *et al.* (2002), Feduccia (1999), Hall (1972), Hume & Davison (1878), Irestedt *et al.* (2001), Keast (1972), Kingdon (1989), Lambert & Woodcock (1996), Lesson (1831), Lowe (1931), Oates (1883), Olson (1971), Peters (1951), du Pont & Rabor (1973), Prum (1993), Raikow (1987), Sclater (1872, 1888), Sibley (1970, 1996), Sibley & Ahlquist (1990), Sibley & Monroe (1990, 1993), Smythies (1999), Strange (2000, 2001), Stuart Baker (1922-1935, 1934), Webster (1991), Wells (1985a, 1988).

#### The Visayan Wattled

**Broadbill** is one of three threatened members of the family. It is considered Vulnerable. Restricted to lowland forest on three islands in the Philippines, it has been recorded from just one site since the 1980s, although at least this was in a protected area. Forest loss on all three islands where the species is, or was, found has been so great that the species now has a very small potential range and seems to be facing a fairly bleak plight.

[*Sarcophanops samarensis*, Rajah Sikatuna National Park, Bohol, Philippines. Photo: Pete Morris]

PLATE 1

inches 4  
 cm 10

**Food and Feeding.** Insects. Orthopterans and metallic beetles recorded on Bioko. In Cameroon, recent observations of birds catching grasshoppers, crickets, cicadas (Cicadidae) and a butterfly, and a female seen with bill full of caterpillars during breeding season.

**Breeding.** Breeding coincides with the dry season: Nov-Apr in Cameroon, Dec on Bioko, and Feb-Sept in Zaïre (few records, season probably as long as for *S. rufolateralis*). Nest a bag of plant fibres, moss and lichen with long hanging "tail", lined with dry leaves, or sometimes built entirely of fine black fungal fibres (*Marasmius*) and dried leaves, or of green moss, or of mosses with old fern strands and lichens: suspended from a small branch 1-16 m above forest floor. Clutch 2 eggs, sometimes 1; incubation and fledging periods unrecorded, but expected to be much as for *S. rufolateralis*.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Poorly known. In parts of Cameroon where it has been studied it is not uncommon, and is apparently evenly distributed throughout the forest. Rare on Bioko. Presence confirmed from only one site in N Gabon and one site in Equatorial Guinea (Mbini): first found in Nigeria in 1995. Status in E Zaïre unclear, but published records suggest that it is not uncommon. This species is able to survive in old logged forest, but seems unable to tolerate seriously degraded habitats.

**Bibliography.** Basilio (1963), Bates (1905), Borrow & Demeý (2001), Bowden (2001), Chapin (1953), Chittenden (1999), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1996, 1998, 1999), Fishpool & Evans (2001), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1970), Moreau (1966), Payne *et al.* (1997), Pérez del Val (1996), Pérez del Val *et al.* (1994), Prigogine (1980, 1984a), Robertson (1994), Stuart (1986).

### 3. Rufous-sided Broadbill

#### *Smithornis rufolateralis*

**French:** Eurylaime à flancs roux

**Spanish:** Eurilaimo Flanquirojo

**German:** Weißbinden-Breitachen

**Other common names:** Red/Red-sided Broadbill

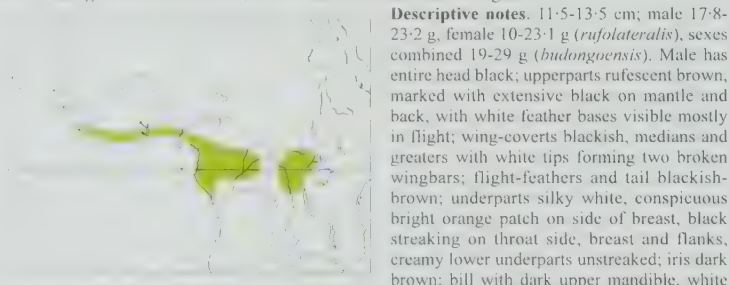

**Taxonomy.** *Smithornis rufolateralis* G. R. Gray, 1864, Ghana.

Sometimes considered to form a superspecies with *S. capensis*, but latter probably more closely related to *S. sharpei*. Races very similar, *budongoensis* possibly not tenable. Two subspecies recognized.

**Subspecies and Distribution.**

*S. r. rufolateralis* G. R. Gray, 1864 - I: Sierra Leone I: to W Zaïre, S to SW Congo and N Angola (Cabinda).

*S. r. budongoensis* van Someren, 1921 - EC & NE Zaïre and W Uganda.

to yellowish-white lower mandible; legs and feet olive-green. Differs from *S. sharpei* in smaller size, white wingbars, less intense orange restricted to side of breast, all-black head. Female has head rufous-tinged dark brown indistinctly streaked darker, upperparts rufous-brown with little or no black, browner wings, underparts washed with greyish or buffish, primarily on flanks, duller orange breast sides. Juvenile has upperparts bright rufous, crown often similar but sometimes darker than mantle and back, tips of median coverts buff but outermost spot usually white or creamy, underparts like female but darker orange on breast side. Race *budongoensis* differs from nominate only in having fewer and shorter dark stripes below, crown of female greyer. **VOIC.** Weak, plaintive, high-pitched short whistle, variously as "wee wee thew thew" or "huiiii"; these and other rhythmic calls run together to form simple song in courtship. Frog-like mechanical trill during display-flight a very loud staccato "ttt-rrrrrrrrrrrr" c. 0.7 seconds long, starts abruptly, slows and accelerates, then ends abruptly, similar to that of *S. capensis* but higher-pitched.

**Habitat.** Primary and secondary forest in lowlands, locally to 1500 m; often near water. Preference for dense growth, particularly in tangles of lianes, and also in logged forest. Unlike *S. capensis*, it occurs in old regrowth on land previously under cultivation.

**Food and Feeding.** Insects and other arthropods. Examination of stomach contents of 20 specimens revealed orthopterans (grasshoppers, crickets), coleopterans including click beetles (Elateridae), ants, an earwig (Dermaptera); also a spider and a millipede (Diplopoda). Observations indicate that small cicadas (Cicadidae) and small hairless caterpillars are favoured items: a male once observed feeding a small, green cicada to nestlings. Often catches flying insects. In Liberia, usual foraging height 3-15 m, but regularly caught in mist-nets below 2 m. Reported rarely in mixed-species foraging flocks.

**Breeding.** In Liberia, breeds in Feb-Aug in N and Aug-Feb in SE; Sept-Apr in Cameroon and Gabon, or possibly starting earlier, with peak of egg-laying in Jan; Dec-Oct in Zaïre and Jun in Uganda. Nest an untidy bag c. 15-17 cm long with hanging "tail" and with entrance hole 3.5-5.5 cm wide c. 3 cm from top, built variously of coarse dead leaves, bamboo leaves, plant and palm-frond fibres, mossy roots and dry twigs, thickly interwoven with long, fine black fungal strands (*Marasmius*), sometimes with moss around entrance, and lined with soft leaf material or fine fibres; suspended 1-2 m above the ground from horizontal branch or creeper by means of fibres. Clutch 1-2 eggs, usually 2; female incubates, and both sexes feed chicks; when female is absent, male clings to entrance hole to guard nestlings; incubation and fledging periods not documented.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common, possibly with larger range than hitherto reported. Occurs in several protected areas, e.g. Gioia Forest Reserves in Sierra Leone, Yapo Reserve in Ivory Coast, and a number of national parks. No records from Togo since 1902. In Liberia, estimated densities based on vocalizations were 4 pairs/km<sup>2</sup> in S Gio National Forest, 6-10 pairs/km<sup>2</sup> in the Niabo area, and 14-25 pairs/km<sup>2</sup> and locally up to 3 pairs/10 ha in area N of Zvedru. A study in Gabon suggested a population density of 12 pairs/km<sup>2</sup>. Can be common in one area and rather rare nearby: e.g. in Cameroon, fairly common in Korup National Park but rare on nearby Mt Kupé; apparently a similar situation in E. Zaïre, where can be locally common or scarce.

## Family EURYLAIMIDAE (BROADBILLS)

### SPECIES ACCOUNTS

**Bibliography.** Allport *et al.* (1989), Bannerman (1936), Bates & Ogilvie-Grant (1911), Borrow & Demeý (2001), Bowden (2001), Brosset & Énard (1986), Chapin (1953), Cheke & Walsh (1996), Chittenden (1999), Colston & Curry-Lindahl (1986), Davidson (1978), Dean (2000), Demeý & Fishpool (1991, 1994), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1999), Elgood *et al.* (1994), Fishpool & Evans (2001), Gartshore *et al.* (1995), Gatter (1997), Germain (1992), Grimes (1987), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1957, 1970), Nash (1990), Ntiamoa-Baidu, Asamoah *et al.* (2000), Ntiamoa-Baidu, Owusu *et al.* (2000), Prigogine (1971, 1980, 1984a), Rand *et al.* (1959), Rodewald *et al.* (1994), Sayer *et al.* (1992), Serle (1950), Short *et al.* (1990), Thiollay (1985), Thomas (1991), Traylor (1960), Waltert (2000), Waltert *et al.* (1999).

## Subfamily CALYPTOMENINAE

### Genus *CALYPTOMENA* Raffles, 1822

#### 4. Green Broadbill

##### *Calyptomena viridis*

**French:** Eurylaime vert

**German:** Smaragdbreitachen

**Spanish:** Eurilaimo Verde

**Other common names:** Lesser Green Broadbill

**Taxonomy.** *Calyptomena viridis* Raffles, 1822, Bengkulu District, south-west Sumatra.

Distinctive race *siberu* may warrant species status. Birds from S Myanmar S to C Malay Peninsula described as race *continentis*, but indistinguishable from earlier-named taxon *caudacea*. Bornean population possibly separable as race *gloriosa*, but existing museum specimens too old and faded for assessment, and insufficient recent material available for examination. Three subspecies recognized.

**Subspecies and Distribution.**

*C. v. caudacea* Swainson, 1838 - S Myanmar (Tenasserim), SW Thailand and Malay Peninsula, including islands of Rah and Phuket; formerly also Singapore, and probably Pinang I.

*C. v. viridis* Raffles, 1822 - Sumatra, Nias I, Batu Is, Lingga Archipelago, N Natuna Is and Borneo.

*C. v. siberu* Chasen & Kloss, 1926 - Mentawai Is (Siberut, North Pagai, South Pagai).

**Descriptive notes.** 14-17 cm, 18.5-19 cm (*siberu*); 43-72.8 g. A plump, green bird with short bill, short tail and unusual tuft of feathers on forehead; broad, pointed wings in flight. Male is iridescent green with yellow spot anteriorly above eye, narrow paler eyering, prominent black spot behind ear-coverts, broad black bars and patches on wings, black flight-feathers edged green; forehead tuft almost covers bill; iris dark brown or blackish; bill black to greyish, paler lower mandible olive, yellowish cutting edges; legs and feet green to olive-green. Differs from *C. hoxii* in having no blue on underparts, no

black on nape, black on wings in form of bars, not spots; from *C. whiteheadi* by much smaller size, much less black in plumage. Female is paler green, without black markings, forehead tuft less pronounced, brighter lime-green eyering. Juvenile resembles female, breast very pale greenish, belly and undertail-coverts paler greenish-white, primaries browner; immature male like adult female, but with bright pale green spot just before and above eye, diffuse blackish spots on wing, sometimes some blue feathers on head. Race *caudacea* is on average marginally paler and larger than nominate; *siberu* is largest and darkest, male with plumage washed bright blue, particularly apparent below, female duller than previous, especially above, but sometimes some blue feathers on nape. **VOIC.** Variety of distinctive, sometimes quiet, calls, often with bubbling, liquid quality; most frequently heard a soft, bubbling trill, starting with quieter note, that increases in tempo and has upward inflection, "toi, toi-oi-oi-oi-oi-oi-oi"; also "ooo-turr", like sound of a stone bouncing on glass. In captivity, two variations of this or a similar call described as "goik-goik" and "goik-goik-doyik", with final syllable faster and higher, probably as alarm but perhaps also as contact calls; also, in display, series of c. 7 faster "goik" notes each accompanied by a head-bob; also, "doy-doy-ee-oh" by captive male considered territorial courtship song, with corresponding call by female very quiet and more as "go-hohohohoho" or "coo-whowhowhowho"; also, various wheezes, whines and cackling notes by male.

**Habitat.** Mostly rainforest and mixed dipterocarp forest, usually in understorey and lower levels, locally also riverine and heath forest, tidal swamp-forest and peat-swamp-forest. Found also in overgrown *Albizia* plantations, rubber estates, cocoa plantations, timber plantations adjacent to forest and secondary forest, where records suggest that these habitats used mostly when foraging; also forages at times in lightly and heavily logged forest. Mostly in lowlands and hills, to 900 m in Peninsular Malaysia; in Borneo usually below 700 m, but recorded to 1200 m; to 1700 m in Sumatra.

**Food and Feeding.** Fruit; also occasionally invertebrates, particularly insects, and these sometimes fed to young in great quantity; emerging termites (Isoptera), for example, caught in flight. Fruits of wide variety and size range taken, particularly figs (*Ficus*), those with large seeds, and lipid-rich arillate ones (e.g. *Eugenia*, *Knema*, *Horsfieldia*), also large fruits of understorey palms, and hard, oily fruits of *Canarium*; in S Borneo, fruits of the Meliaceae and the Myristicaceae a major food source. At study site in Peninsular Malaysia, a radio-tracked male spent 30-70% of total observation time over 5 days, and a female c. 50% of time over 7 days, in or near specific fruiting fig trees, demonstrating importance of figs in this area; diet included fruits of 21 species of strangling or epiphytic figs ranging in size from 5.4 × 5.9 mm to as big as 32.4 × 27.4 mm; daily foraging ranges of four birds were at least 2.5-6 ha, and 1 female covered c. 13 ha in 7 days and 1 male c. 24 ha in 6 days. All food, even largest fruits, usually swallowed whole; sizes of regurgitated seeds recorded from as small as 1 × 1 mm up to 24.2 × 16.2 mm (ripe-fruit size 27-30.5 × 18-23 mm). Most foraging is carried out in the lower levels and understorey of forest, but upper levels and forest edge also visited at times. Fruits plucked from tree when perched or snatched while flying past; also seen to pick fallen fruit from ground.

**Breeding.** Breeds in Feb-Apr in Myanmar; in Malay Peninsula apparently after heavy rains of early part of NE monsoon, Mar-Jun in Thailand and May-Aug in Malaysia; Sept in Sumatra and Jul on Nias I; in Borneo during driest part of year, Jan-Jun. Nest constructed by female, taking c. 5

days, a neat, laterally compressed, compact gourd-shaped structure of plant fibres such as strips of palm and bamboo leaves, rootlets and dead leaves, sometimes with green moss added, and lined with fine, dried leaves, grass-like fibres or hair-like black roots; typical dimensions c. 23 × 10 cm, with "tail" up to c. 65 cm but usually shorter, with elongated side entrance 7.5-8.9 cm tall and 5.6-4 cm across, relatively small nest-chamber 14-16.5 cm high and 7.5-8.9 cm wide; suspended cross-wise about half-way along small branch or twig of sapling or small tree, usually 1-2 m above ground, once from twig hanging over water. Clutch 1-3 eggs, usually 2, the first laid 3 days after copulation, the next 3 days later; in study in Borneo replacement clutch laid after predation, and a captive pair, when eggs removed, laid 2 more at 2-day interval 3 weeks later; in captivity, only female incubates, period 17-18 days, the young fledging when 22-23 days old. From 6 nests in Borneo, fledging success 0-5 young per pair.

**Movements.** Essentially resident, but some nomadism associated with seasonality of fruiting trees. Evidence supports theory that numbers at specific localities vary according to availability of food; 4 trapped at 1300 m at Fraser's Hill, in Peninsular Malaysia, had probably moved because of scarcity of food resources in their normal lower-lying range.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Fairly common or locally common where suitable primary forest remains. Occurs in a number of protected areas, such as Khao Nor Chuchi Wildlife Sanctuary, in Thailand, Panti Forest Reserve and Taman Negara National Park, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, and Gunung Mulu National Park, in Borneo. Last reported from Singapore in 1941, and from nearby Ubin I in 1927; old records from Pinang I are not considered acceptable, but the species probably occurred there in the past. On W Sumatran islands the only recent records are from Siberut, where it is common in suitable habitat. In Borneo, a population density of 60 birds/km<sup>2</sup> recorded for a forest site in Sarawak; over two survey periods at Similajau National Park, Sarawak, this was the only eurylaimid found at all sites in both surveys. As an understory frugivore, however, this species suffers dramatic decline in response to logging; surveys in selectively logged forest revealed densities of only c. 10-25% of the normal level 9 years after operations ceased, and numbers were still low 22 years after logging. Numerical declines of this nature could seriously affect the regeneration of understory plants with large seeds, such as palms, since no other fruit-eating bird with a broad gape regularly feeds in the understory.

5. Hose's Broadbill

*Calyptomena hosii*

**French:** Eurylaime de Hose **German:** Fleckenflügel-Breittrachen **Spanish:** Eurilaimo de Hose  
**Other common names:** (Hose's) Magnificent (Green) Broadbill, Blue-bellied Broadbill

**Taxonomy.** *Calyptomena Hosii* Sharpe, 1892, Mount Dulit, 3000 ft [c. 900 m], Borneo. Monotypic.  
**Distribution.** N & C Borneo, patchily from Mt Kinabalu S to the Muller Range and Kayan Mentarang.

**Descriptive notes.** 19-21 cm; male 102-115 g, female 92 g. Male is bright iridescent green above, with forehead tuft hiding most of bill; thin pale green eyering, black spot before eye, black patch behind ear-coverts, black patch on nape and another across top of mantle, prominent black rounded spots on wing-coverts; flight-feathers black, edged green; below, indigo-blue on breast and deep blue on belly and undertail-coverts; iris blackish; bill horn-coloured to blackish; legs and feet dark olive. Distinguished from other *Calyptomena* by blue on underparts, from *C. viridis* also by spots rather than bars on wing. Female has smaller forehead tuft, paler upperparts slightly olive-tinged, black on head restricted to small spot in front of the eye, prominent lime-green eyering, paler lime-green underparts with sky-blue on belly and undertail-coverts. Juvenile is like female, but male has dark feathers on lower nape; immature male like adult, but most of black head markings lacking, blue below less extensive. **VOICE.** Only call recorded, uttered during bobbing head movements, is a pleasing, soft, cooing like that of a dove (Columbidae).

**Habitat.** Upper zone of mixed dipterocarp forest on hill slopes, and lower montane forest; also forest dominated by limestone pinnacles, and lowland forest on mountain slopes. To c. 1220 m, usually above 600 m, occasionally as high as c. 1680 m.

**Food and Feeding.** Mostly fruit, including figs (*Ficus*), also unidentified soft greyish-yellow berries; once observed eating small orange figs c. 1 × 1 cm in size and covered in short, spiny hairs. Also recorded eating leaf buds, and some insects. Forages usually at lower levels, and singly, in pairs, or in small groups; parties of 6-8 gather at fruiting fig trees.

**Breeding.** Few records, covering Apr-Oct. Nest a delicate hanging structure; one found recently measured c. 25 × 15 cm, was made of dead leaves of broadleaf plants, rattans and bamboos, and covered in green moss and lichens, with a hanging "tail" of rattan leaves, and suspended from tip of a low drooping branch c. 1.5 m high of an understory tree. Two clutches were of 2 and 4 eggs; incubation and fledging periods not known.

**Movements.** Resident; probably makes some local movements, depending on seasonality of fruiting trees.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Bornean Mountains EBA. Locally common, but rare at some sites (e.g. Mt Kinabalu). Occurs in Gunung Mulu National Park. Areas where it is common are undisturbed forest. In Sarawak, becomes rare in forest after logging activities. Although absent from some apparently suitable habitats, it may yet prove to be more widespread than records indicate, particularly in C Borneo. Lowland forest in the region has been severely reduced, and is expected

to have been destroyed completely within less than a decade. The species' preference for submontane habitats could assist its survival, at least in the short term.

**Bibliography.** Andrew (1992), Banks (1935), Büttikofer (1901), Collar *et al.* (2001), Dekker *et al.* (2000), Fogden (1965, 1976), Holmes (1997), Hose (1898), MacKinnon & Philipps (1993), Robson (1993b), Sharpe (1892, 1894), Sheldon *et al.* (2001), Smythies (1999), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), Wells (1985b), Wells *et al.* (1979).

6. Whitehead's Broadbill

*Calyptomena whiteheadi*

**French:** Eurylaime de Whitehead **Spanish:** Eurilaimo de Whitehead  
**German:** Schwarzkehl-Breittrachen  
**Other common names:** Black-throated (Green) Broadbill

**Taxonomy.** *Calyptomena whiteheadi* Sharpe, 1888, Mount Kinabalu, 3000 ft [c. 900 m], Borneo. Monotypic.

**Distribution.** N & C Borneo, probably along entire spinal range from Mt Kinabalu S at least to Mt Latuk and Kayan Mentarang, although known to be absent from several mountain areas.

**Descriptive notes.** 24-27 cm; male 142-171 g, female 150-163 g. The largest green broadbill, with obvious black markings. Male has vivid green plumage, with forehead tuft almost hiding bill; some black on crown, prominent black spot behind ear-coverts and another on nape, extensive black on wings and mantle; flight-feathers and tail blackish, secondaries edged green; large, bold black patch on lower throat and centre of upper breast, green below with prominent black streaking; iris dark brown; bill black, paler lower mandible; legs and feet olive to green-grey. Distinguished from other *Calyptomena* by much larger size, black throat

patch, more extensive black markings on wings and body. Female slightly smaller than male, feather tuft less pronounced, lacks black head spots, underparts duller green with no black markings other than throat patch. Immature similar to adult, but fewer black markings. **VOICE.** Snoring, grinding or wheezing disyllabic calls characteristic, e.g. "toc-trrrr" with second syllable a grinding noise, coarse, harsh, rather abrupt "kerrrrr" or "kh-khrrrrr" repeated by group of 3-4 perched males, also as "chek, rrrrr-trrrr" and "teek-waaaaarrt"; also staccato "eek-eek-eek" reminiscent of woodpecker (Picidae) and hissing "ee-ooo", possibly as alarm calls; also short, very harsh, woodpecker-like "tzip" directly followed by coarse rattle 2-3 seconds long, and in flight an interposed rapid phrase of harsh notes very like those of a woodpecker; also hollow, deep search call like that of a trogon (Trogonidae), "go-up", imitation of which attracts bird. Other calls include shrill "saat", loud harsh call like that of jay (Corvidae), snore-like wheeze, and other hissing and grinding noises.

**Habitat.** Montane forest, also forest edge; preference for tall growth, and not found in areas of stunted forest. At 900-1700 m, but can occur as low as 600 m and as high as c. 1980 m.

**Food and Feeding.** Mostly fruits, some insects. Fruits vary in size from small berries up to drupes larger than plums, and recorded as taking the strong-smelling fruits of *Litsea cubica* (Lauraceae); fruits up to 15 × 20 mm in size found in stomachs. Most items swallowed whole, and even large seeds are regurgitated whole. Insects recorded in one stomach, and observed taking moths at dawn from around lights in Mount Kinabalu National Park. Forages usually singly, but occasionally in small, noisy groups at fruiting trees; sometimes perches on tree trunks when feeding. Occasionally joins mixed-species foraging flocks.

**Breeding.** Few records; breeding season probably at least Mar-Jun. One nest described, suspended from slender branch c. 15 m above ground, exterior built of fresh green moss, solid interior lined with dry bamboo leaves and forming well-sheltered pocket, and with long "tail" of moss and lichen giving camouflage effect against the numerous streamers of moss and lichen hanging from adjacent branches. Clutch 1-2 eggs, based on three nests; no information on incubation and fledging, or on roles of sexes.

**Movements.** Normally resident. During severe drought conditions of 1997/98, one bird seen in forest at elevation of c. 75 m at Maau, on R Bengalun (E Kalimantan), far from mountains. Otherwise, probably some local movement dependent on seasonality of fruiting trees.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Bornean Mountains EBA. Relatively common in suitable habitat, which remains extensive at its preferred altitudinal range. Occurs in Gunung Mulu and Mount Kinabalu National Parks. Poorly known; research required, especially on its breeding behaviour and biology.

**Bibliography.** Andrew (1993), van Balen (1997), Banks (1937, 1952), Davison (1992), Dekker *et al.* (2000), Fogden (1970), Gibson-Hill (1952), Holmes (1997), Hose (1898), MacKinnon & Philipps (1993), Pfeffer (1960), Robson (1993b), Sheldon *et al.* (2001), Smythies (1999), Stattersfield *et al.* (1998), Sujatnika *et al.* (1995), Wells (1985b).

Subfamily EURYLAIMINAE

Genus CYMBIRHYNCHUS

Vigors, 1830

7. Black-and-red Broadbill

*Cymbirhynchus macrorhynchos*

**French:** Eurylaime rouge et noir **Spanish:** Eurilaimo Rojinegro  
**German:** Kellenschabel-Breittrachen  
**Other common names:** Common Rouge-et-noir Bird; Allied Broadbill, Arakan Black-and-red Broadbill (*affinis*)

**Taxonomy.** [*Todus*] *macrorhynchos* J. F. Gmelin, 1788, no locality = Borneo.

Considerable individual variation throughout most of range renders defining of geographical races difficult; apparent general clinal trend in certain characters, such as increase in size and decrease in amount of white in tail from N to S, but no constant differences between populations; variation in characters used to define races requires further study. Described races *lemniscatus* (Sumatra, Bangka I and Belitung I) and *tenebrosus* (SE Sumatra) considered synonymous with nominate; *siamensis* possibly inseparable from *malaccensis*. Four subspecies recognized.

#### Subspecies and Distribution.

*C. m. affinis* Blyth, 1846 - SW Myanmar.

*C. m. siamensis* Meyer de Schauensee & Ripley, 1940 - S Myanmar (Tenasserim), SW & S Thailand (except extreme S), Cambodia, S Laos and S Vietnam.

*C. m. malaccensis* Salvadori, 1874 - extreme S Thailand and Peninsular Malaysia; formerly also Singapore.

*C. m. macrorhynchus* (J. F. Gmelin, 1788) - Sumatra, Bangka I, Belitung I, and Borneo (including Pulau Laut, off S coast).

**Descriptive notes.** 20-24 cm, 50-76 g. Distinctive broadbill with carmine-maroon underparts and brightly coloured bill. Both sexes have broad maroon throatband extending to ear-coverts, green-glossed black crown and upperparts, maroon rump and uppertail-coverts; scapulars elongated and pointed, white on outer webs; wing-coverts black, edges glossed blue-green, orange on marginal coverts; flight-feathers blackish, concealed white bar at bases; tail blackish, outer 1-2 feather pairs sometimes with very small whitish patch near tip of inner webs; broad black breastband, remaining underparts dark maroon, sometimes with patches

of orange on belly and flanks; iris green to blue; upper mandible bright blue, lower mandible yellow; legs and feet blue. Juvenile is browner, with white spots on wing-coverts, patches of maroon below. Races differ mainly in size, and in amount of white in tail and wings: *affinis* is smallest, has crimson spots on innermost secondaries, more conspicuous white wing spot, more white on tail, narrow black feather edges on rump; *malaccensis* has maroon colours slightly paler, more orange-yellow spotting below; *siamensis* is generally slightly smaller than previous, with reduced orange spotting below, usually more white on tail, sometimes thin black edges on rump feathers, but variable. **VOICE.** Often silent, with calls quieter than those of most eurylaimids. Most frequently heard call in Laos an accelerating series of "parnk" notes, likened to sound of wingbeat of Wreathed Hornbill (*Rhyticeros undulatus*); other calls include grating notes as if from a cicada (Cicadidae), churring calls, melodious whistles, monotonous repeated "tyook", rasping "wiark", also ascending trill like that of *Eurylaimus ochromalus* but shorter, much slower, softer; alarm a rapid series of "pip"; in Sarawak, hoarse, grumbling "ka-ka-kraaar-kraaar" falling in pitch; in Brunei, hoarse twanging "cow", and a snarl likened to that of cornered puma (*Felis concolor*).

**Habitat.** Prefers lowland forest near rivers and streams, including evergreen and semi-evergreen forest, mixed dipterocarp forest, riverine forest, swamp-forest of various kinds, mangroves; also plantations near water, including rubber estates, also locally in villages and gardens. Occurs also in secondary forest in logged areas where some scattered tall trees remain, and in lower secondary vegetation with clumps of open forest in pastureland. Persists in disturbed habitats, even seriously degraded areas along rivers. To 300 m in most of range; locally to 900 m in Sumatra and Borneo.

**Food and Feeding.** Small invertebrates, mostly insects, form bulk of diet; some small fruits and other vegetable matter also taken. Recorded items are orthopterans, beetles, ants, hemipteran bugs, moths, caterpillars, molluscs, freshwater snails, and freshwater crustaceans including small crabs; once a small fish. Most information based on stomach contents. Fruit found in stomachs included not only pulp, but also seeds and berry stones, and once a leaf; for at least some individuals, fruit probably no more than a local or seasonal component of diet. Observations of feeding scant, but notably include the catching of moths fluttering over small streams.

**Breeding.** Scattered records over most of range suggest breeding in drier months of year: Feb-Jun in Myanmar, May-Jun in Thailand, May and Jan in Laos, Jul-Aug in Cambodia, Feb-Aug in Peninsular Malaysia, Mar-Jun in Sumatra, and Dec-Aug in Borneo. Nest built by both sexes, work sometimes taking up to 49 days, a conspicuous ragged pear-shaped structure with dangling "tail", built of tightly interwoven grass, vines, sticks, bark strips, leaves, creepers, vegetable fibres, rootlets, fungal hyphae and pieces of moss, interior lined with e.g. reed-grass or palm fronds and floor covered with green leaves and other softer material, side entrance hole with "roof" of grass or fibres; size variable, 30-65 cm deep and 12-25 cm broad, nest-chamber 10-15 cm deep and 7-8 cm across, diameter of entrance hole 4-5 cm; suspended from end of a branch or vine 1-5-8 m over water (river, stream or lake, occasionally pool, tidal mangrove or drainage ditch), more rarely over path or road, or more vulnerable site (e.g. telephone wire, or pole emerging from water), once in isolated bush in open rice paddy, and once near wasp nest. Clutch 2-3 eggs, occasionally 4, laid at rate of 1 per day; incubation apparently by both sexes; incubation and fledging periods unrecorded. Success variable, nests on overhead wires destroyed by strong winds, those low down or attached to poles vulnerable to flooding; in Peninsular Malaysia, at least 6 of 17 nests destroyed before breeding completed.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Occurs in several protected areas, including Nam Bai Cat Tien National Park, in Vietnam, Taman Negara National Park and Pantli Forest Reserve, in Peninsular Malaysia, and Gunung Leuser and Way Kambas National Parks, in Sumatra. Formerly very common to abundant, but has decreased considerably. Now generally rare in N of range following lowland deforestation; fairly common in peninsular Thailand, where able to survive in logged areas if tall trees and moist secondary growth remain along riverbanks; scarce in most of Indochina but can be locally common, even in degraded forest, e.g. in S Laos. In late 19th century was apparently common in Mergui Archipelago, in S Myanmar, but current status in those islands unknown. In Peninsular Malaysia, relatively common where suitable habitat remains; presumably occurred formerly on Pinang I, but no confirmed records. Extinct in Singapore since first half of 20th century. Rather scarce although widely distributed in Sumatra; in Borneo, common in lowlands but very rare in interior and at higher altitudes. As with many forest species, it is vulnerable to disturbance; nevertheless, is able to survive if some suitable habitat mosaics near water remain.

Genus *PSARISOMUS* Swainson, 1837

## 8. Long-tailed Broadbill

*Psarisomus dalhousiae*

**French:** Eurylaime psittacin **German:** Papageibreitrachen **Spanish:** Eurilaimo Lorito  
**Other common names:** Yellow-throated Broadbill

**Taxonomy.** [*Eurylaimus*] *Dalhousiae* Jameson, 1835, Himalayas, at 10,000 feet [c. 3000 m], northern India; this altitude is above normal range and type probably from near Simla. Variation within accepted races unclear and somewhat complex. In particular, birds from N Indochina (possibly also S China) with more white in collar are sometimes separated subspecifically as “*assimilis*”, while race *divinus* may be closer to latter or is possibly indistinguishable from some *cyanicauda*. Peninsular Malaysian birds, although included in *psittacinus*, are less distinctively patterned than Sumatran population and may be closer to nominate, or possibly represent an undescribed race. Further taxonomic study required. Five subspecies recognized.

**Subspecies and Distribution.**

*P. d. dalhousiae* (Jameson, 1835) - Himalayan foothills E from N India and Nepal, possibly SE Bangladesh, and from N Myanmar and S China (W & S Yunnan, SW Guizhou, SW Guangxi) S to N Thailand, Laos and C Vietnam (C Annam); also reported from SE Tibet.

*P. d. cyanicauda* Riley, 1935 - SE Thailand and Cambodia.

*P. d. divinus* Deignan, 1947 - S Vietnam (S Annam).

*P. d. psittacinus* (S. Müller, 1836) - Peninsular Malaysia and Sumatra.

*P. d. borneensis* Hartert, 1904 - N Borneo.

**Descriptive notes.** 23–26 cm, 64–67 g, 52–8 g (*borneensis*). Distinctive slim, very long-tailed, colourful broadbill. Adult of both sexes has black cap with blue crown patch, yellow spot on nape side, bright yellow face, throat and almost complete collar, usually small blue nuchal patch; generally little or no white in collar (but in N Indochina often whitish or pale yellow feathers at bottom edge, especially near nape); upperparts green; flight-feathers black, basal two-thirds bright blue; long, graduated tail blue, undertail black; paler green below, often tinged blue, in NW (Nepal E to N Myanmar) underparts sometimes mostly turquoise; blue underwing with prominent white patch on flight-feathers; iris green to grey-brown, sometimes partly pink; bill greenish, with bluish base; legs and feet light green to greenish-yellow. Juvenile has green crown, pale yellow on lores and behind ear-coverts, greenish-yellow chin and throat. Races vary in size, including tail length, and in colour of, especially, the collar and tail: *cyanicauda* has darker tail than nominate, outer webs strongly washed green; *divinus* resembles previous, but green of upperparts brighter and deeper in tone, tail not quite so dark and green wash on tail side reduced, nuchal patch more extensive and more clearly defined, female nuchal patch more blue-edged yellow; *psittacinus* is shorter-winged and longer-tailed than other races on mainland, in Sumatra collar admixed white and yellow, white usually predominant and often extending narrowly across upper breast, female usually differing in having partly or fully concealed yellow band across nape, but in Peninsular Malaysia pattern less distinctive, with greater resemblance to nominate race; *borneensis* is like *psittacinus* but smaller, tail slightly paler, more ultramarine-blue than other races. Voice. Series of loud, sharp, downward-inflected whistles, “tseeay” or “pseew”, repeated 5–8 times at increasing speed, usually in flight or on take-off; at other times, occasional single, sharp “tseeay” or “pseew”, and short, rasping “psweep”.

**Habitat.** Large variety of forest habitats occupied over its wide range, including primary and secondary tropical evergreen, semi-evergreen and subtropical broadleaf forest, mixed deciduous forest including areas adjoining pine (*Pinus*) forest, and bamboo-dominated areas; in Indian Subcontinent, some preference for forested ravines with little undergrowth, and with running water or temporary pools. Sometimes visits more open areas, including gardens, in cold weather. In India usually c. 600–1200 m, occasionally to c. 2000 m, but at 200–1830 m in NE; 275–1340 m in Nepal, and to c. 1800 m in Bhutan and Myanmar; 700–1500 m in China; c. 650–2200 m in Thailand but lower, to 1525 m, in Indochina; 150–1550 m, mostly above 800 m, in Peninsular Malaysia; 700–2500 m in Sumatra and 900–1700 m in Borneo.

**Food and Feeding.** Almost exclusively invertebrates, mostly insects; claims of fruit and berries eaten are unsupported. Recorded items cover orthopterans, cicadas (Cicadidae), beetles, cockroaches (Blattodea), hemipteran bugs, butterflies, large ants, caterpillars and other insect larvae and pupae; also spiders. Single record of 2 small green tree-frogs being consumed. Forages from canopy down to undergrowth. Insects and other prey gleaned from foliage, along branches and trunks, occasionally by climbing trailing creepers and hanging branches; aerial prey also captured in fluttering sallies from different perches. In non-breeding period occurs in small, noisy foraging parties of c. 15 birds, rarely more, but occasionally up to 40 together; groups or pairs will also briefly join mixed-species flocks.

**Breeding.** Relatively few documented records. Season Mar–Aug in Indian Subcontinent; from Apr in Myanmar, but fresh eggs found in Aug (probably rare second brood, if first lost); Feb–Sept in Thailand and Mar–Jul in Indochina; Feb–May in Peninsular Malaysia, Feb–Aug in Sumatra and from Mar in Borneo. Conspicuous bulky pear-shaped nest with long “tail”, built by both sexes, sometimes with helpers, usually within c. 3 weeks, material including creeper stems and tendrils, fine roots, dead leaves, palm fibre, fern fronds and stems, twigs, liverworts and mosses, sometimes adorned with green moss and spider egg cases, side entrance usually with small “roof”, interior chamber lined with grass blades or roots and bamboo leaves overlaid with green leaves, latter sometimes replaced during incubation; nests measured in India varied from 23 × 12.7 cm to 35.6 × 20.3 cm, chamber 10–12.5 cm wide with entrance hole c. 4–5 cm across, total length with “tail” up to c. 1.4 m, usually shorter; usually suspended from tip of branch or creeper, once from telegraph wire, up to c. 30 m above ground, usually lower, and often above stream, path or open area; same site may be used in successive seasons, up to 6 old nests found in single tree. Clutch 4–8 eggs, usually 5–6 in India, 3 in Peninsular Malaysia; both adults participate in incubation and in feeding

of young, sometimes with helpers, e.g. 5 attending nest in Borneo; incubation period unrecorded, suggested as more than 14 days; fledging period not known.

**Movements.** Resident in most of range; in Himalayan foothills, some altitudinal migration during cold weather.

**Status and Conservation.** Not globally threatened. Occurs in many national parks and other protected areas throughout its range. Formerly common over most of its range, but now disappearing or becoming uncommon to scarce over large areas. Still locally common in some localities where suitable habitat remains, e.g. in Nagaland, NE India. Apparently decreasing significantly in NE parts of range; scarce and local in Nepal, and possibly extinct in Bangladesh, although it could survive in Chittagong Hill Tracts; in Myanmar, recent records from only few sites in W, and uncommon in extreme N during two surveys in 1998 and 1999. Locally common or uncommon in Thailand, where some young birds end up in the domestic cagebird markets; becoming rare and isolated in much of Indochina; considered uncommon in China. Locally common in Peninsular Malaysia, although increasingly scarce and local in Borneo and also apparently in Sumatra; recently recorded (vocalizations taped) in Kayan Mentarang National Park, East Kalimantan, the first record from Indonesian portion of Borneo.

Genus *SERILOPHUS* Swainson, 1837

## 9. Silver-breasted Broadbill

*Serilophus lunatus*

**French:** Eurylaime de Gould **German:** Schwarzbrauen-Breittrachen **Spanish:** Eurilaimo Pechoplata

**Other common names:** Collared/Gould’s Broadbill; Hodgson’s Broadbill, Red-backed Broadbill, Nepal Collared Broadbill (*rubropygius*); Pegu Collared Broadbill (*lunatus*)

**Taxonomy.** *Eurylaimus lunatus* Gould, 1834, hills of Pegu District, Myanmar.

Race *rubropygius* was formerly considered a separate species, as thought to be sympatric with nominate in two areas, but recent examination of critical specimens indicates that ranges do not overlap, although closely approaching each other in NE Myanmar; one old record from Chin Hills, in NW Myanmar, attributed to nominate, remains unresolved. Status of some isolated populations, particularly in SE Thailand and Indochina, and the boundaries between and validity of several races, are poorly understood and require further study; *atrestus* and *aphobus* often synonymized with *elisabethae*, while birds occurring in lowland S Laos are considered probably to belong to *atrestus*, rather than to *impavidus*, which is better treated as confined to Bolaven Plateau. Described races *intrepidus* (NE Thailand) and *moderatus* (N Sumatra) considered unacceptable. Ten subspecies recognized.

**Subspecies and Distribution.**

*S. l. rubropygius* (Hodgson, 1839) - NE India, Bhutan and E Bangladesh E to W & NE Myanmar (Arakan, Chin Hills and Upper Chindwin E to R Irrawaddy).

*S. l. atrestus* Deignan, 1948 - C & E Myanmar (S of Bhamo, E of R Irrawaddy) and S China (SW Yunnan) S to NE Thailand, C & S (lowland) Laos and NW Vietnam (W Tonkin).

*S. l. elisabethae* La Touche, 1921 - SE China (SE Yunnan, SW Guangxi) and E Tonkin.

*S. l. polionotus* Rothschild, 1903 - Hainan I.

*S. l. lunatus* (Gould, 1834) - SC & S Myanmar (Pegu Yomas, Karen Hills, N Tenasserim) and NW Thailand.

*S. l. stolidus* Robinson & Kloss, 1919 - S Myanmar (S Tenasserim) and SW & S Thailand (except extreme S).

*S. l. aphobus* Deignan, 1948 - SE Thailand and Cambodia.

*S. l. impavidus* Deignan, 1948 - Bolaven Plateau, in S Laos.

*S. l. rothschildi* Hartert & Butler, 1898 - extreme S Thailand and Peninsular Malaysia.

*S. l. intensus* Robinson & Kloss, 1916 - Sumatra.

**Descriptive notes.** 16–17 cm; 33–35 g (*rubropygius*), 25–234 g (*intensus*). Male has pale rusty head, lores usually darker rusty, forehead often ash-grey, and broad black supercilium; upperparts ferruginous, greyer on mantle, bright rufous rump and uppertail-coverts; wing-coverts blackish; flight-feathers strikingly blue and black, white band across base (conspicuous in flight), tertials orange-rufous; tail black, outer feathers tipped white; light ash-grey below, becoming white on belly and undertail-coverts; iris green to dark blue, yellowish orbital ring; bill blue to greenish-blue, orange base; legs and feet yellowish to olive.

Female is like male, but with narrow silver band across upper breast. Juvenile resembles adult, but wings and tail much shorter, plumage somewhat darker. Races differ mainly in head coloration, wing pattern, tone of upperparts and underparts: *rubropygius* differs from nominate in having dark grey lores, pale grey crown to upper mantle, darker brownish-grey rest of upperparts, silver

breastband of female broken in centre, from all other races in narrower, broad dark blue tips of outer webs of flight-feathers, darker blue secondary-bar, white subterminal spots on outer webs of secondaries, less developed supercilium, greyer underparts; *elisabethae* has lores blackish, side of head and ear-coverts pale rusty, rump and uppertail-coverts deeper rufous, less bright; *atrestus* resembles previous, but lores tinged rusty, side of head and upperparts distinctly lighter and brighter; *impavidus* is similar, but with ashy hue on upper back and scapulars, and reddish colour on crown, upperparts and tertials on average paler; *aphobus* resembles last, but lores blackish-rusty, side of head more vivid ferruginous; *polionotus* has lores black, head pale ashy with darker olive-brown tinge, upper back and scapulars ashy, darker grey breast contrasting with paler ashy throat; *stolidus* has extensive very pale ash-grey on forehead, darker, more chestnut, lower back and rump; *rothschildi* has lores pale ashy, side of head greyish without ferruginous or brownish tinge, bluish upper edge of black supercilium, more extensive bluish on bend of wing, rufous on upperparts extending from lower mantle to tail-coverts, female tends to have broader white breastband; *intensus* resembles last, but lores blackish-ash. **VOICE.** Generally silent, calls mostly in vicinity of nest. Melancholy "ki-uu" or "pee-uu", likened to sound of rusty hinge, commonly heard; thin, high-pitched, grating insect-like trill of 5-7 notes, "kitikitikit", given in flight, possibly as alarm; distinctive contact call, "pri-iiip", heard in S Laos; loud mouse-like squeaking given by mist-netted bird when disturbed.

**Habitat.** Tropical and subtropical evergreen and semi-evergreen forest, also mixed deciduous forest, including areas dominated by pine (*Pinus*), oak (*Quercus*) and bamboo; in some areas considered to occur in all forest types, including selectively logged forest; also enters agricultural lands and gardens. To c. 1700 m in India, but at c. 250 m in Bhutan; usually c. 300-900 m, occasionally to 1220 m, in Myanmar, and 300-700 m in China; usually 800-1800 m, sometimes to 2230 m, in Thailand; lower in Indochina, to 800 m in Cambodia, 700 m in Laos, and 365 m in Vietnam; 600-1220 m, rarely down to 150 m, in Peninsular Malaysia; 800-2000 m in Sumatra.

**Food and Feeding.** Invertebrates, primarily insects; records from India and Myanmar include grasshoppers, mantises (Mantidae), smaller unidentified insects, larvae, caterpillars, also small land snails. Recent report of a 10-cm lizard eaten by this species was an error, the record being referable to *Eurylaimus javanicus*. Insects taken by flycatching from perch, moving from one perch to another, although flight heavy and awkward; more often by gleaning branches and foliage, from undergrowth to below the canopy; also observed extracting larvae from tree bark, and once flying to a road puddle either to drink or to take an insect. Forages in pairs or in loose groups of up to 20 individuals, usually fewer. Will also join mixed-species flocks foraging in understorey; in N Vietnam, a group of 12 of these broadbills was considered to form the core of a mixed flock.

**Breeding.** At higher latitudes breeds in spring with arrival of rains, but farther S in drier season, pattern coinciding with movements of the SW monsoon: May-Jun in India; Mar-Jul in Myanmar but probably over longer season in S; in Thailand, Aug-Dec in N and Mar-May in S; Mar-Jun in Vietnam; Apr-Jun in Peninsular Malaysia; Mar in Sumatra. Nest a pendant ball with long, loose hanging "tail", usually neater-looking than those of most other broadbills, built by both sexes, sometimes with helpers, estimated construction time 5-10 days, material including coarse grass, outer bark of elephant grass, weeds, thin twigs, fine roots and fungal hyphae, frayed palm pieces and green moss, interior lining of broad grass blades, green leaves and other material, green leaves regularly replaced during incubation; tail may be decorated with moss, lichen, spider egg cases and other material after eggs laid; size varies, can be as large as 76 cm tall and 30.5 cm wide, but generally c. 25-38 × 10-20.5 cm, including "tail", and circular entrance hole c. 4 × 2.7 cm with "hood" projecting c. 2 cm outwards; suspended across entire width by mass of interwoven plant fibres from outer branch of small tree, tip of palm frond or bamboo, or bush or tree-fern, at height of 1-7 m, mostly 3-5 m, over open space such as road, path or small stream; if nest destroyed, replacement usually built nearby; active nests within 70 m of each other recorded. Clutch 2-7 eggs, usually 4-5, but 2 or 3 in Peninsular Malaysia; both sexes, sometimes with helpers, incubate eggs and feed chicks; incubation and fledging periods unrecorded. Eggs of cuckoos (Cuculidae) found in nests in S Myanmar and Sumatra.

**Movements.** Resident in most of range; in Himalayan foothills apparently an altitudinal migrant, moving to lower areas during cold winter months.

**Status and Conservation.** Not globally threatened. Formerly considered very common over most of its range; now disappearing or becoming uncommon to scarce over large areas, although still locally common where suitable habitat remains. Occurs in several protected areas throughout range: e.g. Namdapha National Park, in India, and scarce in Lawachara/West Bhanugach Reserve Forest, in Bangladesh; also in Xishuangbanna Nature Protection Zone, in China; at least three protected areas in Thailand, Nam Nao, Khao Yai and Kaeng Krachan National Parks; and present in Cuc Phuong National Park, in Vietnam. Recorded in Nepal in 19th century, now extinct; rare and local in Bhutan, where recorded in a few localities in S; probably much reduced in other parts of region from NE India to Myanmar. In two recent surveys in extreme N Myanmar, found to be uncommon in 1998 (900-1200 m) but none recorded in 1999. Uncommon in N Thailand, but fairly common in other areas of that country, where it is still supplied to the domestic cagebird markets; numbers much reduced in Indochina, although still being found in new localities; very rare in China. Uncommon to locally common in Malay Peninsula and Sumatra.

**Bibliography.** Ali & Ripley (1948, 1983), Ali *et al.* (1996), Bangs & Van Tyne (1931), Betts (1956), Chasen & Hoogerwerf (1941), Cheng (1983), Choudhury (2001), Deignan (1945, 1948), Dekker & Dickinson (2000a), Dekker *et al.* (2000), Delacour (1951), Delacour & Greenway (1940), Delacour & Jabouille (1940), Duckworth & Hedges (1998), Duckworth *et al.* (1999), Eames & Robson (1992), Engelbach (1938), Etchécopar & Hùe (1983), Evans & Timmins (1998), Evans *et al.* (2000), Garthwaite & Teehurst (1937), Gee (1997a), Ghosh (1987), Grimmett *et al.* (1998), Hopwood (1919), Inglis *et al.* (1920), Inskipp *et al.* (1999), Jeyarajasingam (1983), Jeyarajasingam & Pearson (1999), King *et al.* (2001), Lambert & Woodcock (1996), Lekagul & Round (1991), MacKinnon & Phillips (1993, 2000), van Marle & Voous (1988), Mayr (1938a), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Oates (1879), Ripley (1982), Robinson (1927), Robinson & Kloss (1918a), Robson (2000d), Round (1988), Singh (1994), Smith (1943), Smith *et al.* (1943), Smythies (1986), Stepanyan (1995), Stevens (1925), Stuart Baker (1921, 1934), Wells (1985b, 1986, 1990a, 1990b, 1990c).

## Genus *EURYLAIMUS* Horsfield, 1821

### 10. Banded Broadbill

#### *Eurylaimus javanicus*

**French:** Eurylaimé de Horsfield

**Spanish:** Eurilaimo Bandeado

**German:** Purpurkopf-Breittrachen

**Other common names:** Horsfield's/Purple-headed Broadbill

**Taxonomy.** *Eurylaimus javanicus* Horsfield, 1821, Java.

Distinctive morphological differences of nominate race, with pure yellow vent and without breastband, could suggest that it should be treated as a separate species from other races. Birds from Belitung I named as race *billitonis*, but identical to some *harterti*; in addition, both *friedmanni* and *pallidus* are frequently also lumped with that race, but the former, at least, seems generally distinguishable; further reappraisal of mainland populations required. Five subspecies currently recognized.

#### Subspecies and Distribution.

*E. j. friedmanni* Deignan, 1947 - SE Myanmar, Thailand (S to Isthmus of Kra) and Indochina.

*E. j. pallidus* Chasen, 1935 - S Thailand (S from Isthmus of Kra) and Peninsular Malaysia; formerly also Singapore.

*E. j. harterti* van Oort, 1909 - Sumatra, Riau Archipelago (Bintan), Bangka I and Belitung I.

*E. j. brookei* Robinson & Kloss, 1919 - Borneo and N Natuna Is.

*E. j. javanicus* Horsfield, 1821 - Java.

**Descriptive notes.** 21.5-23 cm; 74-84 g (*pallidus*), 73-87 g (*brookei*). A large, distinctive broadbill with purple, yellow and black plumage. Male has purple-red head, black lores; mantle dark brown, back blacker with yellow streaks, central back with concealed white feather bases, rump and uppertail-coverts yellow and black; wing-coverts blackish; flight-feathers dark brown, primaries with some small yellow spots, secondaries with bright yellow fringes forming patch; tail black, whitish spots near tip visible on undertail; underparts light purple-pink, undertail-coverts pure yellow; iris blue; bill blue, greenish tip.

black cutting edges; legs and feet greyish-violet. Female has hindcrown glossed grey, faint purplish band on upper mantle, throat and upper breast washed greyish. Juvenile is duller, head and upperparts pale brown marked with yellow, rows of large yellow spots on wings, pale yellowish-white throat, buffy breast to belly, sooty band across upper breast; immature has crown strongly washed with shades of yellow-green, purple markings on side of head, neck and belly. Races differ from nominate in larger size, maroon undertail-coverts, male with narrow black band across upper breast; *friedmanni* has metallic grey wash below, throat and upper breast appearing rosy violet; *pallidus* resembles previous, but is more vinaceous pink below with weaker grey wash; *harterti* is very like last, but darker on head and below, mantle maroon, underparts dark pink to pinkish-maroon, black breastband well developed, iris ultramarine to emerald-green; *brookei* differs from previous in blackish forehead, often pinker throat, less prominent breastband, iris usually greyish, occasionally light blue, female with less black on forehead. **VOICE.** Usual call a brief, sharp "wheoo", followed immediately by a loud, rising, rapid insect-like trill 5-6 seconds long which increases in tempo, final 2 or 3 notes fading away at lower pitch, often as duet with 1 bird starting shortly after other; can be stimulated to call by sudden loud noise (e.g. thunder, slamming of car door), but reported to respond sluggishly to tape playback; also, nasal "whee-u", descending "kyeow" squeak, rolled "keowr", yelping "keek-eeek-eeek".

**Habitat.** Variety of forest types, including logged forest, but particularly evergreen and mixed deciduous forest near streams and rivers, peat-swamp-forest, upland heath-forest and freshwater swamp-forest; also forest edge, overgrown rubber estates, *Albizia* groves, gardens, parks and around villages. Mostly to 1050 m; to 1220 m in Borneo and to 1500 m, probably mainly 500-900 m, in Java; apparently a lowland species in Indochina, but to c. 1100 m in Laos.

**Food and Feeding.** Predominantly insects, including orthopterans (grasshoppers, crickets, katydids), various beetles, homopteran and heteropteran bugs, caterpillars and other larvae; also spiders, small snails. In a study in Borneo, orthopterans eaten by this species found to be generally larger, c. 55 mm in length, than those taken by *E. ochromalus*. Small fruits, including figs (*Ficus*), recorded as eaten in Java and Sumatra; also, a bird found in Myanmar had the tail of a 10-cm lizard still protruding from its bill, suggesting that this was an unusually large prey item. Most prey plucked from foliage, including from underside of leaves, while in flight; often sits motionless, apart from searching movements of head, frequently directed upwards, then makes irregular, fluttering flight to glean prey before alighting on nearby perch. Also observed to flycatch in more elegant fashion. Pairs and small groups can be active all day.

**Breeding.** Breeds mainly during dry period following NE monsoon, with apparently extended season in S: Mar in S Myanmar, Jul and Dec in Thailand, Jun in Laos, Feb-Sept in Peninsular Malaysia, Mar-Nov in Sumatra, Apr on Belitung I, Nov-Jun in Java and Mar-Sept in Borneo. Nest, possibly built by both sexes, a huge, ragged-looking pear-shaped structure 75-90 cm long including hanging "tail", compactly woven from available material, mostly small twigs, roots, leaves, grass, moss (dead and fresh) and leaf skeletons, chamber lined with leaves, lateral entrance hole almost concealed by large "porch" made of twigs, leaves and grass, exterior decorated with e.g. lichen, green moss, caterpillar excreta and cocoons fastened with cobwebs, tendrils and plant stems, suspended c. 2.5-21 m up from thin branch close to tree trunk or from tall branch overhanging stream; a nest in Peninsular Malaysia was sited 0.5 m from active bees' nest, presumably for protection provided by the bees. Clutch 2-3 eggs; incubation and fledging periods unrecorded; in study in Borneo, parents still provided 70-80% of food to young 13 weeks after fledging, falling to 20-30% at 20 weeks.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon or locally common in Indochina, rare in N Thailand; locally common in suitable habitat in S part of range, but rare in NW Borneo (Brunei) and C & E Java. In Borneo, estimated density c. 10 birds/km<sup>2</sup> in primary forest at a site near Kuching (Sarawak). Occurs in several protected areas, e.g. Khao Yai and Kaeng Krachan National Parks and Khao Nor Chuchi Wildlife Sanctuary, in Thailand, Nam Bai Cat Tien National Park, in Vietnam, Taman Negara National Park and Panti Forest Reserve, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, and Gunung Gede-Pangrango National Park, in W Java. In 1990 recorded from E Java, and in 1995 confirmed as still present on Bintan I (Riau Archipelago). Although recently thought to have become extinct in Singapore in 1950, it probably disappeared much earlier; old records from Pinang I (West Malaysia) considered not acceptable, but it may have occurred there in past. Earlier accounts indicate that this broadbill has long been locally common, uncommon or scarce through most of its range.

## 11. Black-and-yellow Broadbill

### *Eurylaimus ochromalus*

**French:** Eurylaime à capuchon **Spanish:** Eurilaimo Negrigualdo  
**German:** Halsband-Breittrachen

**Taxonomy.** *Eurylaimus ochromalus* Raffles, 1822, Singapore.

Birds from Banyak Is (off NW Sumatra) described as race *mecistus* and those from W Borneo (Saribas District of Sarawak) as race *kalamantan*; there is, however, considerable individual variation among all populations, which makes recognition of any geographical races hardly tenable. Monotypic.

**Distribution.** S Myanmar (Tenasserim), SW & S Thailand, Peninsular Malaysia, Riau Archipelago, Lingga Archipelago, Sumatra (including Banyak Is, Batu Is), Bangka I, Belitung I, N Natuna Is and Borneo (including Pulau Laut, off S coast).

**Descriptive notes.** 13.5-15 cm, 31-39 g. A small, distinctive broadbill with black, white, pink and yellow plumage. Male has black head and upperparts, broad white collar, conspicuous bold yellow markings on back and wings; blackish tail, yellowish spots on central feathers, whiter spots on outer ones; black breastband, rest of underparts vinaceous-pink, fading to pale yellow on belly and undertail-coverts; iris pale yellow; bill bright turquoise to cobalt-blue, green tip of upper mandible, black cutting edges; legs and feet horn-pink to bluish. Female has breastband broken in centre. Juvenile lacks distinct breastband, has pale

yellow supercilium, greyish-white underparts. **VOICE.** Insect-like bubbling trill, similar to that of a cicada (Cicadidae), starts with a few spaced sharp downslurred notes, rises and accelerates gradually into low quivering trill 8-12 seconds long, not unlike trill of *E. javanicus* but longer, acceleration slower, no introductory whistle, abrupt termination; often both partners call alternately, slightly overlapping; calls in response to sudden loud noises, less so to tape playback; also, plaintive, shrill "peep" by bird in company of trilling pair; other calls include guttural "keowrr" and squeaking "kyeeow", also "kor kor kor" by male at nest.

**Habitat.** Wide range of forest types occupied, including evergreen forest, mixed dipterocarp forest, heath-forest, swamp-forest (both freshwater and coastal), forest edge, secondary growth, also overgrown plantations, including cocoa, rubber and *Albizia*; adapts to logged forest and secondary habitats where large trees remain. To 700 m in Myanmar, Thailand and Peninsular Malaysia, to 900 m in Sumatra and to c. 1220 m in Borneo.

**Food and Feeding.** Primarily insects, including orthopterans (grasshoppers, crickets, katydids), mantises (Mantidae), various beetles (e.g. Cerambycidae, Scarabaeidae), hymenopterans, flies, alate termites (Isoptera), and caterpillars; in Borneo, found to consume smaller orthopterans (length c. 35 mm) than those taken by *E. javanicus*. Some small molluscs also recorded taken; also, stomach of 1 Bornean specimen contained orange-red berries with large dark pips, but evidence suggests fruit a very incidental component of diet. Small, scattered groups usually forage in middle and upper levels of forest. Flocks of up to 10-15 reported; solitary individual foraging from an exposed perch, usually in open parts of the canopy, may be occupying a lookout position as a member of a dispersed group. Usually sits quietly on perch, searching for prey; makes brief sallies to take prey from leaf surfaces while in flight, returning to different perch. Aerial insects (e.g. termites) sometimes seized in mid-air. Also observed clinging to tree trunks like a woodpecker (Picidae) when foraging. On occasion, individuals briefly join mixed-species foraging flocks.

**Breeding.** Most records coincide with onset of the dry season, but wide range of dates reported: Feb-Oct on mainland, Jan-Jul in Sumatra and Mar-Aug in Borneo. Large, untidy, pear-shaped hanging nest of moss, fungal mycelia and leaf skeletons, chamber lined with rough grass roots, bamboo leaves and leaf stalks, dimensions of 1 nest c. 17 × 13 × 10 cm, walls c. 3-8 cm thick, entrance hole 5 × 6-4 cm with protruding "step" below, and attached by loops of e.g. cane, grasses or twigs; usually suspended from branch or similar suitable site, including trees in plantations, 5-18 m above ground or water surface, but once in dense lower part of canopy c. 15-20 cm inside edge of foliage; some in Borneo placed close to bees' nests, this apparently a characteristic site for species there. Clutch 3 eggs, occasionally 2; no information on incubation and fledging periods. Nests sometimes parasitized by cuckoos (Cuculidae) in Peninsular Malaysia: records of adults feeding young of Indian Cuckoo (*Cuculus micropterus*), also of adults feeding unidentified cuckoo fledgling (Sept), and of clutch containing unidentified cuckoo egg.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Occurs in Kaeng Krachan National Park and Khao Chong Reserve and Khao Nor Chuchi Wildlife Sanctuary, in Thailand, in Taman Negara National Park and Pantu Forest Reserve, in Peninsular Malaysia, and in Kerinci-Seblat and Way Kambas National Parks, in Sumatra. Originally thought to be common to abundant throughout its range, and still considered locally common wherever suitable habitat remains. In Borneo, a study in primary forest near Kuching (Sarawak) indicated a population density of c. 10 birds/km<sup>2</sup>, and recent reports from Sabah suggest that the species survives well in logged forest. In W Sumatran islands all records are pre-1970, but available habitat suggests that it may still be present. Said to have been extirpated in Singapore in 1879, a date based on a single old record, but exact year of its disappearance uncertain; old records from Pinang I (W Malaysia) considered not acceptable, but probably occurred there at some time in the past. Habitat destruction within its range has been severe and extensive, with lowland forest drastically reduced and expected to have been destroyed completely within less than a decade. Despite its tolerance of secondary habitats, the species seems likely to survive in the long term only in protected parts of its range and in higher-lying forested areas.

## Genus *SARCOPHANOPS* Sharpe, 1879

## 12. Mindanao Wattled Broadbill

### *Sarcophanops steerii*

**French:** Eurylaime de Steere **German:** Graurücken-Breittrachen **Spanish:** Eurilaimo de Mindanao  
**Other common names:** Steere's/Mindanao Broadbill; Wattled Broadbill (when lumped with *S. samarensis*)

**Taxonomy.** *Eurylaimus Steerii* Sharpe, 1876, Basilan, Philippines.

Genus often merged into *Eurylaimus*, but significant morphological differences. At the same time was considered conspecific with *S. samarensis*, but the two differ strikingly in plumage coloration and better treated as forming a superspecies. Race *mayri* possibly not always separable from nominate; further study needed. Two subspecies recognized.

**Subspecies and Distribution.**

*S. s. steerii* (Sharpe, 1876) - SW Mindanao (Zamboanga Peninsula), Malamaui and Basilan, in Philippines.

*S. s. mayri* (Salomonsen, 1953) - Dinagat, Poneas, Siargao and C, S & E Mindanao.

**Descriptive notes.** 16.5-17.5 cm; 33.7-44.4 g (*mayri*). Distinctive eurylaimid with prominent blue eye wattles. Male has maroon-purple forehead and crown, black face and throat, white collar; mantle and back dark grey, lower back to tail rufous, rump and uppertail-coverts with purple wash; wings black, prominent white band on tertials, yellow band across secondaries; underparts lilac, centre of belly to vent yellowish-white; iris green to blue or yellow, blue fleshy wattle up to 6 mm wide around eye; bill light blue; legs and feet bluish. Differs from *S. samarensis* in larger size, whiter collar, grey on upperparts, yellow in wing. Female is like

male, but underparts pure white. Immature has white throat, gradually becoming black, olive-green crown and wash on upperparts, ill-defined wingbar more buffish-pink than white, eye wattle yellow. Race *mayri* is slightly smaller than nominate, male underparts usually paler. **VOICE.** Poorly known; one call said to be a plaintive whistle.

**Habitat.** Rainforest; dipterocarp and mixed dipterocarp forest, including remnant patches, hillside secondary forest, also secondary forest close to undisturbed riverine forest; occasionally mangroves, scrub forest. Mostly lowlands, usually well under 1000 m; occasionally to 1220 m.

**Food and Feeding.** Insectivorous, but no details of prey species. Forages at middle and lower levels, singly, in pairs, or in small flocks of up to 6 birds. Makes short sallies to glean insects from vegetation, or to seize them in flight, before returning to same or nearby perch; also observed chasing insects by jumping from branch to branch. Insects may be beaten against a branch before being swallowed. Sometimes in mixed-species foraging flocks.

**Breeding.** Few records; females with egg in oviduct in Apr-May, and immatures in Apr, Aug, Dec and Jan; main season probably Apr-Jun. Nest described as large, elaborate, shaped like hanging purse. No other data.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Mindanao and the Eastern Visayas EBA. Uncommon to rare on Mindanao, Basilan and Malamaui; recently considered fairly common on Dinagat and Siargao, but now very local and uncommon on both islands. Since 1980, recorded at only a handful of sites, three of those in Mindanao and including Mount Apo National Park; also from Siargao (a protected area) and Poneas. As with all forest broadbills, this species is sensitive to habitat disturbance; has probably disappeared from many areas, such as in S Mindanao. Deforestation of lowlands has occurred extensively throughout its range, and is continuing at rapid pace; little original forest is left on any of the islands occupied by this species, and most remaining forest lies above 1000 m. This broadbill's range is almost certainly now highly fragmented, and its numbers are thought to be in serious decline.

**Bibliography.** Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Dekker & Dickinson (2000a), Dekker *et al.* (2000), Delacour & Mayr (1945, 1946), Dickinson *et al.* (1991), Evans *et al.* (1993), Gee (1997b), Gonzales & Rees (1988), Hachisuka (1934), Kennedy *et al.* (2000), McGregor (1909-1910), duPont (1971), duPont & Rabor (1973), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 13. Visayan Wattled Broadbill

### *Sarcophanops samarensis*

**French:** Eurylaime de Samar **Spanish:** Eurilaimo de las Visayan  
**German:** Purpurrücken-Breittrachen

**Other common names:** Samar/Visayan Broadbill; Wattled Broadbill (when lumped with *S. steerii*)

**Taxonomy.** *Sarcophanops Samarensis* Steere, 1890, Catbagan, Samar, Philippines.

Genus often merged into *Eurylaimus*, but significant morphological differences. Was at same time considered conspecific with *S. steerii*, but the two differ strikingly in plumage coloration and better treated as forming a superspecies. Monotypic.

**Distribution.** Philippine islands of Samar, Leyte and Bohol.

**Descriptive notes.** 14.5-15 cm; 33.5-41.5 g. Distinctive eurylaimid with prominent blue eye wattles. Male has black throat, lores and ear-coverts, purple crown, mottled grey nuchal collar; mantle purple, lower back to tail rufous with purple tinge; wings black, prominent whitish band across tertials and lilac-pink band across secondaries and tertials; underparts lilac, centre of belly to undertail-coverts yellowish-white; iris variably green, orange or blue (dependent on angle of light), broad sky-blue fleshy wattle around eye; bill bluish; legs and feet bluish to greyish. Differs from *S. steerii* in smaller size, grey hindcollar, purple man-

tle, lilac in wing. Female resembles male, but underparts pure white. Juvenile has dark brown head with grey-washed crown, whitish collar, olive and grey-brown upperparts tinged rufescent, grey-brown underparts. **VOICE.** Calls rarely: insect-like "tik, tik, t-rrrrrrrr", usually twice with interval of 2-3 seconds; not unlike a *Eurylaimus* call or call of Blue Fantail (*Rhipidura supercilialis*); also, short, rather quiet whistles heard on Bohol, possibly contact call.

**Habitat.** Primary forest, frequently in areas with limestone outcrops. Usually in lowlands, at 100-600 m on Samar and c. 300-750 m on Bohol; rarely to c. 600 m on Leyte.

**Food and Feeding.** Records mention only "small insects" and, once, a green caterpillar. Forages singly, in pairs, or in small groups up to 5 individuals, usually at lower levels of forest. Sometimes joins mixed-species foraging flocks.

**Breeding.** Birds in breeding condition and moulting in Mar-May, young juveniles in May and Jul, and immatures in Apr, Jul and Aug. Nest not known, presumably similar to that of *S. steerii*. No other data.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Since 1980 recorded only from Bohol, where not infrequent in Rajah Sikatuna National Park; thought to be still present elsewhere on that island, but normally silent and unobtrusive, and believed to be probably under-recorded. Formerly considered locally abundant on Samar, and possibly still locally common in first half of 20th century; present status there and on Leyte uncertain, but probably rare. Range very small and habitat loss severe, with vast majority of forested areas already destroyed; this species' presence on forested limestone outcrops is considered not so much a characteristic trait, but the consequence of habitat loss elsewhere. Most of the small areas of surviving lowland forest are under immediate threat from logging and other damaging operations; even in Rajah Sikatuna illegal tree-cutting activities and expansion of agriculture pose threats, although these pressures now being minimized by recent management initiatives. Population and area of distribution almost certainly still decreasing very rapidly. Further research required to determine this broadbill's ecology and breeding biology, as well as its current status. The identification of suitable sites for protection should be then treated as a priority.

**Bibliography.** Brooks *et al.* (1996), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Dekker & Dickinson (2000a), Dekker *et al.* (2000), Delacour & Mayr (1946), Dickinson *et al.* (1991), Gee (1997b), Gonzales & Rees (1988), Hornsokov (1996), Kennedy *et al.* (2000), McGregor (1909-1910), Parkes (1973), duPont (1971), Rabor (1938), Rand & Rabor (1960), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## Genus *CORYDON* Lesson, 1828

### 14. Dusky Broadbill

#### *Corydon sumatranus*

**French:** Eurylaima corydon **German:** Braunkehl-Breittrachen **Spanish:** Eurilaimo Sombrio

**Taxonomy.** *Coracias Sumatranus* Raffles, 1822, interior of Sumatra.

Individual variation considerable. Several described races considered probably untenable: *morator* (from S Thailand), *ardescens* (SE Thailand) and *khmerensis* (Cambodia and S Indochina) regarded as inseparable from *laensis*, and *pallascens* (Thai-Malay Peninsula) better treated as synonymous with *sumatranus*; *orientalis* possibly indistinguishable from *brunescens*; further study of geographical variation is desirable. Four subspecies recognized.

**Subspecies and Distribution.**

*C. s. laensis* Meyer de Schauensee, 1929 - S Myanmar, Thailand (except extreme S) and Indochina.

*C. s. sumatranus* (Raffles, 1822) - extreme S Thailand S to Sumatra.

*C. s. brunescens* Hartert, 1916 - N Natuna Is and NW Borneo (Sarawak).

*C. s. orientalis* Mayr, 1938 - Borneo (except NW).

**Descriptive notes.** 24-28.5 cm; c. 140 g. A big, thickset, blackish broadbill with massive pinkish bill, small white patch in the primaries. Adult has blackish-brown head and body, crown and nape sometimes tinged olive, rump and uppertail-coverts strongly olive-tinged; concealed area of pale orange and white feathers, rarely also few scarlet ones, on mantle; wings brown, white at bases of primaries; tail brown, all but central feather pair with white subterminal bar, variable in extent; throat and upper breast whitish with variable amount of orange-brown feather edgings, rest of underparts dark brown; iris dark brownish-red, purplish orbital skin; bill variable, pinkish to yellowish-horn, usually purple with tip light blue-grey, grey cutting edges; legs and feet pinkish-grey or browner. Juvenile is much browner, no orange feathers in mantle, less white in wing and tail, darker throat. Races differ mainly in colour of throat patch, amount of olive in plumage, and colour of concealed dorsal spot, but variable: *laensis* is darker than nominate, more sooty black, with whiter throat, more scarlet-coloured dorsal spot, perhaps more purple-toned bill and facial skin; *brunescens* is much browner than previous, without olive tones, throat usually much deeper rufous-brown, dorsal spot scarlet; *orientalis* is on average larger than previous, throat much paler, more buff than rufous. **VOICE.** Commonest call a series of c. 6-8 screaming notes on ascending scale, "hi-ky-ui, ky-ui, ky-ui, ky-ui, ky-ui" with "ky" note stressed, sometimes notes more as "pee-u" with terminal "ki-ip"; other calls include shrill, thin "pssecoo", high piercing "tsiu", far-carrying croak and rattling laugh; in Laos, repeated quavering "ch whit" in flight, and 4-7 accelerating "chwoo" or "phwoo" notes and occasionally "pepepepepe" near nest; in Thailand, clear, whistled "pee-u" in flight.

**Habitat.** Primary forest, logged evergreen and deciduous forest, mixed dipterocarp forest, also mossy forest at higher altitudes; also forest on limestone, freshwater peat swamp-forest, gallery forest, and tall trees at plantation edges. Lowlands and hills, up to 1220 m in Myanmar, at least 1000 m in Thailand, and 2000 m in Indochina; possibly as high as 1525 m in Peninsular Malaysia; to c. 1000 m in Sumatra and locally to 1830 m in Borneo; to 300 m in N Natuna Is.

**Food and Feeding.** Insects, including orthopterans (grasshoppers up to 10 cm long, crickets), beetles (e.g. Scarabaeidae), large hemipteran bugs, large flying insects, ants; also small lizards. Prey gleaned from branches and leaves after a brief sally; large aerial insects also captured by upward leap from perch. Gregarious; occurs in foraging groups of up to 10-20, most active in early morning and evening, and often noisy. Also spends much time in perching silently, searching for

prey. Forages in upper storey of forest, at 15-30 m, generally much higher up than other broadbills in same areas.

**Breeding.** The few records indicate nesting in late dry season in N, but earlier, in wettest part of year, farther S: Mar-May in Myanmar but Dec-Jun in Tenasserim; Apr-Dec in Thailand, Mar-May in Laos and Aug-Sept in Cambodia; Sept-Jun, mostly Mar-May, in Peninsular Malaysia; Feb-Nov in Sumatra and Nov-May in Borneo. Co-operative breeder, up to 10 birds recorded at single nest. Large, bulky but compact pear-shaped structure c. 30 cm wide and often 2 m or more long, with or without hanging "tail" up to 70 cm long, built by adults and usually other group-members, from twigs, small roots, epiphyte strands, bamboo leaves and dry moss, plant stems and similar material, lined with green and dried leaves, and decorated with cocoons, caterpillar excreta, spider egg cases, leaves and other material (e.g. epiphyte runners with small living leaves), with entrance hole 5 x 6 cm about a third down from top and almost concealed by large "porch"; suspended from tip of strong plant part such as branch or palm tendril to hang 4-13 m above open area such as river or pool, dry riverbed, forest clearing or road. Clutch 2-4 eggs; details of incubation and fledging not recorded, and unclear if helpers assist breeding pair in these tasks.

**Movements.** Resident; some records at higher altitudes possibly involve individuals wandering outside normal range.

**Status and Conservation.** Not globally threatened. Generally uncommon. Apparently decreasing, or possibly disappearing, in parts of N Thailand; recent reports from several localities in Laos, but status there uncertain, possibly locally common. Locally common in suitable habitat in Thai-Malay Peninsula, and the same may apply to Sumatra. In Borneo, locally common in some parts (such as E Kalimantan) and scarce in other areas (such as Sabah), and only 3 records from Brunei. Occurs in Kaeng Krachan National Park and Khao Nor Chuchi Wildlife Sanctuary, in Thailand, in Phou Xang He National Biodiversity Conservation Area, in Laos, in Nam Bai Cat Tien National Park, in Vietnam, in Taman Negara National Park and Panti Forest Reserve, in Peninsular Malaysia, and in Way Kambas National Park, in Sumatra. Stated to have become extinct in Singapore in late 19th century, but circumstances unclear; although old records from Phuket I and Pinang I considered not acceptable, it probably occurred on those islands in the past. A study of the effects of logging on bird populations in Sabah suggested that this species and others declined following these operations, although a nest was found in recently logged forest.

**Bibliography.** Anon. (1988d), Bangs & Van Tyne (1931), David-Beaulieu (1932), Deignan (1936b, 1945, 1947), Dekker & Dickinson (2000), Dekker *et al.* (2000a), Delacour (1929, 1951), Delacour & Jabouille (1940), Duckworth, Salter & Khounboline (1999), Duckworth, Tizard *et al.* (1998), Eames & Robson (1992), Engelbach (1938), Evans & Timmins (1998), Evans *et al.* (2000), Gore (1968), Holmes & Burton (1987), Holmes & Philipps (1998), Hopwood (1919), Jeyarajasingam & Pearson (1999), Lambert (1992a), Lambert *et al.* (1994), Lekagul & Round (1991), Lim Kim Seng (1992), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Mayr (1938b), Medway & Wells (1976), Meyer de Schauensee (1946b), Mitra & Sheldon (1993), Nash & Nash (1985), Oberholser (1932), Oustalet (1903), Robinson (1927), Robinson & Kloss (1919a), Robson (1998, 2000d), Robson, Eames, Newman *et al.* (1991), Robson, Eames, Nguyen Cu *et al.* (1993b), Round (1984, 1988), Sheldon *et al.* (2001), Silvius & Verheugt (1986), Smythies (1986, 1999), Stuart Baker (1922-1935, 1934), Thewlis *et al.* (1996), Verheugt *et al.* (1993), Vowles & Vowles (1997), Wells (1985b), Wilkinson *et al.* (1991).

## Subfamily PSEUDOCALYPTOMENINAE

## Genus *PSEUDOCALYPTOMENA*

### Rothschild, 1909

### 15. Grauer's Broadbill

#### *Pseudocalyptomena graueri*

**French:** Eurylaima de Grauer **German:** Blaukehl-Breittrachen **Spanish:** Eurilaimo de Grauer  
Other common names: African Green Broadbill

**Taxonomy.** *Pseudocalyptomena graueri* Rothschild, 1909, 50 miles [80 km] west of Russisi, north of Lake Tanganyika, 2000 m, east Zaire.

The populations in Zaire and Uganda, respectively, were once thought to represent geographical races, separable by bill width, but the difference now considered to be due to individual variation; they do, however, exhibit apparent differences in ecology and behaviour, and further study may demonstrate that they merit taxonomic separation. Monotypic.

**Distribution.** E Zaire (Itombwe Mts; Mt Kahuzi, W of L Kivu) and W Uganda (Bwindi-Impenetrable Forest).

**Descriptive notes.** 13.6-15.6 cm; 29-32.5 g. A small, rather short-tailed, green broadbill. Adult has finely black-streaked buff crown, narrow black eyestripe, light blue ear-coverts, moustachial area narrowly streaked black; nape and upperparts bright green; flight-feathers dark brown, edged green; tail green, tinged blue at base, outer feathers with brown inner webs; chin white, throat and breast pale blue, belly and flanks pale green, undertail-coverts variably all blue to blue-tipped green; iris blackish; bill black; legs and feet grey-green. Immature is duller, with green undertail-coverts. **VOICE.** Weak "tsi-tsi" or "cree-cree" repeated 3-8 times at c. 4 per second, similar to call of Oriole Finch (*Linurgus olivaceus*); in Uganda, also high-pitched "prrrr" at c. 30-second intervals, and high, feeble notes probably as contact; when breeding, long very high-pitched bell-like ringing in flight, but uncertain whether produced vocally or mechanically.

**Habitat.** Occupies primary montane forest, forest edge and bamboo-dominated forest, occasionally occurring in isolated trees in clearings and agricultural areas; 1760-2480 m in Zaire, 2060-2285 m in Uganda. In Zaire, occurs mainly below the bamboo zone, and appears to favour forest edge near cultivation, in areas of dense foliage, preferring upper levels of fairly tall trees; in Uganda, strongly associated with stands of the dominant tree *Chrysophyllum gorungosanum* on steep slopes, seeming to shun valley bottoms and areas where these trees not present in good stands, and prefers

upper portions of understorey. These observations suggest some ecological differences between the two populations.

**Food and Feeding.** Three individuals observed to feed on the orange fruits of *Xymalos monospora* (Monimiaceae). Contents of five stomachs revealed a variety of food items: invertebrates were small beetles, a small snail, insects and insect larvae; vegetable matter comprised small seeds, small flowers, flower buds, remains of small fleshy fruits, and orange and green fruits. When rediscovered, in 1933, was observed in a large tree with abundant juicy berries. Forages singly or in small flocks of up to 10 birds. In Zaire, prefers the upper branches of fairly tall trees at levels of 7.5-25 m. In Uganda, found in upper parts of the forest understorey c. 2.5-3 m from ground and in *Neoboutonia* trees, feeding in the manner of a waxbill (*Estrilda*); also seen to join mixed-species foraging flocks. Sometimes forages near human habitation. In a recent observation in Uganda, 3 individuals feeding at 4-7 m in fruiting trees alternated between active feeding for 10-15 minutes and sitting motionless, either higher up in the food tree or in trees nearby, for 35-50 minutes. In addition, gleans insects from foliage in upward-directed sallies; possibly also takes them in mid-air. Also seen to climb up vertical branches and on underside of horizontal ones in manner of a woodpecker (Picidae), presumably seeking invertebrate prey, behaviour unlike that of other eurylaimids.

**Breeding.** Birds in breeding condition in Jul-Aug, immature seen in Jul and juvenile with adult in Aug in Zaire; fledged young fed by adult in Mar and active nest found in Apr in Uganda. 1 nest found, a spherical structure c. 20-25 cm in diameter with side entrance c. 5 cm wide, with external layer of green lichen, suspended c. 11 m up in mid-canopy from outermost branches of a tree and directly overhanging a stream, in open scrubby vegetation with many 20-m trees; presumed female was sitting in nest while partner perched quietly nearby. No other data.

**Movements.** Resident. Possibly some short local movement; recent Aug record from Mubwindi Swamp, in Bwindi-Impenetrable Forest National Park, Uganda, thought perhaps to have involved an individual outside its normal range.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Albertine Rift Mountains EBA. Quite common but localized in Itombwe Mts, but rare in the Impenetrable Forest; experienced observers in Uganda usually encounter it about once every 2 days. World range very small, and fragmented. Forest clearance around villages, commercial logging and mining activities all identified as potential threats, as well as recent dramatic increases in region's human population owing to huge influx of refugees (large numbers concentrated at foot of Itombwe's E escarpment and N of there); following recent crop failures, clearance for agriculture along edges of gallery montane forest in Itombwe has greatly increased. Species is well protected in Bwindi-Impenetrable Forest National Park, in Uganda. In Zaire, population in the mountains W of L Kivu is perhaps safeguarded in Kahuzi-Biéga National Park, although the area is under threat, and montane habitat in Itombwe, although still relatively intact, is not protected. The presence of seeds in stomachs of this eurylaimid could indicate that it plays an important role in dispersal of seeds of forest plants.

**Bibliography.** Ash *et al.* (1991), Aspenlind (1935), Butynski & Kalina (1993), Butynski *et al.* (1997), Byaruhanga *et al.* (2001), Chapin, J.P. (1953), Chapin, R.T. Class AVES  
Order PASSERIFORMES  
Suborder EURYLAIMI  
**Family PHILEPITTIDAE (ASITIES)**

- Small, short-tailed, largely frugivorous and nectarivorous forest birds, males brightly coloured, two species with long, decurved bill.
- 9-16.5 cm.

- Madagascar.
- Lowland to high-altitude rainforest, humid valleys in dry deciduous forest.
- 2 genera, 4 species, 4 taxa.
- One species threatened; none extinct since 1600.

### Systematics

With their remarkable form and coloration, and occurring exclusively on the island of Madagascar, where so much else is bizarre, the asities have had a long voyage around the taxonomy of the bird world, and one that is clearly not yet over. According to the morphology of the syrinx and the stapes, however, they are clearly suboscines. This puts them in a group with the other Old World suboscines, including the pittas (Pittidae) and the broadbills (Eurylaimidae), and with many New World groups such as the ground-antbirds (Formicariidae). On the basis of hind-limb morphology, DNA-DNA hybridization studies, nest structure and syrinx morphology, the Philepittidae fall into the same clade as the pittas and the broadbills. The proximity of this relationship, however, is unclear. Recent mtDNA cytochrome *b* data, along with syrinx morphology, suggests that they are best considered as a subfamily, Philepittinae, within the Eurylaimidae. Indeed, the syrinx morphology of Grauer's Broadbill (*Pseudocalyptomena graueri*) suggests that that species is closer to the Philepittidae than it is to the other broadbills. It seems likely that an ancestral African broadbill invaded Madagascar around the time when the lineage leading to Grauer's Broadbill split off from the lineage which led to the other African broadbills.

Syrinx morphology and other taxonomically conservative characters clearly show that *Philepitta* asities and *Neodrepanis* sunbird-asities belong in the same group, although on the basis of readily apparent structural differences they have often been treated as forming two separate subfamilies. Indeed, over the years, the two species in the genus *Philepitta* have moved through the starlings (Sturnidae), the birds-of-paradise (Paradisaeidae) and the sunbirds (Nectariniidae), before being eventually confirmed as suboscine. The *Neodrepanis* sunbird-asities are very similar in superficial form to the sunbirds, and it was in the Nectariniidae that they were placed until a 1951 study showed them to possess a suboscine syrinx. The generic name "*Neodrepanis*", incidentally, alludes to the *Drepanis* Hawaiian honeycreepers, which share the extravagantly decurved bill shape. It does not indicate any taxonomic relationship between the two groups.

### Morphological Aspects

The family Philepittidae contains four species in two quite distinct genera. The morphological distinctions from their closest

relatives, the broadbills, include the possession of twelve tail feathers, and the fact that the tarsi are covered with regular scutes, a condition known as taxaspidian scutellation; other distinctive features are a very short tail, an unusually long outer primary, and a syrinx encased in a heavy uppermost bronchial ring. In addition, all four species have a tongue that is adapted to nectar-feeding, with a tip that is more or less markedly forked and brush-coated. The long outer primary makes a slight buzzing noise when the bird flies (see also Voice); this noise, especially in the case of the Yellow-bellied Sunbird-asy (*Neodrepanis hypoxantha*), seems to be some kind of sexual signal, as the emargination of this primary is very marked on males and the buzzing noise is consequently rather loud. There appears also to be a mechanical element, probably produced by the wings, in the noises made during the displays of Velvet Asities (*Philepitta castanea*).

Around the eyes, the breeding males of all four species have remarkable wattles or caruncles, largely blue or green in colour. This colour is produced by ordered arrays of collagen fibres, representing what is, so far as is known, a unique mechanism for colour production in animals. In addition, the wattles have small blisters or papillae over their surface, often, as instanced by the Yellow-bellied Sunbird-asy, with paler or brighter tips. Both *Neodrepanis* species also have a similar patch of brightly coloured skin on the base of the bill. The wattle is present, or is most prominent, in the breeding season, and males are capable of enlarging the wattle when displaying to other males or to females. It is possible to watch, for instance, an agitated male Velvet Asity as it "pumps up" the wattle until the horns over the bill touch. During the non-breeding season, the wattle may be reduced to a narrow, pale pink flap of skin or may even disappear almost completely, this being especially so with Schlegel's Asity (*Philepitta schlegeli*) and the Common Sunbird-asy (*Neodrepanis coruscans*). On other individuals, the wattle may be little less conspicuous than in the breeding season.

All philepittid species also show very marked sexual dichromatism, the males being much the more brightly coloured. The dominant colours are yellow and black, while the two sunbird-asities are, in addition, splendidly marked with iridescent blues on the feathers of the mantle, scapulars, wing-coverts and rump.

Both members of the genus *Philepitta*, the Velvet and Schlegel's Asities, are rotund, almost tailless birds with a slim, slightly decurved, medium-length bill, short wings and, at least in the case of the breeding male, dense, intensely coloured plum-

The asities are endemic to Madagascar and form a family of four species in two distinctive genera. Nowadays it is generally agreed that they are closely related to the broadbills (Eurylaimidae), but in the past the genus *Philepitta* was variously thought to belong with the starlings (Sturnidae), birds-of-paradise (Paradisaeidae) or sunbirds (Nectariniidae). All members of the family are characterized by a short tail, a long outer primary and a tongue that is adapted for feeding on nectar. The brightly coloured caruncle at wattle around the eye of **Schlegel's Asity** is typical of breeding males in all species.

[*Philepitta schlegeli*, Ampijoroa, Madagascar.  
Photo: Simon Harrap]

age. The velvetiness of the black coloration is remarkable, and the bird seems to absorb light as it sits in the forest understorey. The bill length of Velvet Asities does not vary between the sexes, but it does seem to be very variable within the population as a whole, although this phenomenon has not been related to any particular ecological characteristics.

The sunbird-asities are tiny, short-tailed birds with a long, decurved bill and short legs. Their adaptation to nectar-feeding goes further than that of the *Philepitta* asities in that they have a tubular tongue. The bill is extremely narrow at the tip, and is of a similar shape to that of many of the nectar-bearing spurs found on such flowers as *Bakerella* and *Impatiens*. This similarity has suggested to some authors that a co-evolutionary process involving bill shape and flower shape has taken place. On the other hand, many of the flowers at which sunbird-asities feed do not have long spurs, and the bill is often not inserted far into flowers, as the tongue is apparently sufficiently long to reach the nectar.

It appears that all four species in the family have delayed male plumage maturation. Sexually mature males in entirely female plumage have been recorded for the Velvet Asity and for both species of *Neodrepanis*. The moult of the sunbird-asities closely resembles that of the "true" sunbirds of the family Nectariniidae in that both groups have two annual body moults, the first in the year giving rise to an "eclipse" plumage in the male. In the case of the Common Sunbird-asity, and probably the Yellow-bellied species, too, however, the two feather generations are similar on the breast and belly, and only the iridescent upperpart feathers lose their breeding-season brightness. The *Philepitta* asities apparently have only one moult, which is postnuptial, and which, in Velvet Asity males, leads to a "non-breeding" coloration made up of yellow fringes on the majority of the black body and wing-covert feathers. This gives way to a "breeding" plumage through the shedding of the yellow tips, leaving the black feather bases remaining.

The situation with Schlegel's Asity is less clear, as the males appear to have a "non-breeding" plumage that is similar to that of the females. This may indicate that, as with the *Neodrepanis* sunbird-asities, they have two complete moults each year. It is, however, also possible that these female-plumaged birds are subadults, and that, while they are sexually mature, they are exhibiting delayed plumage maturation rather than an "eclipse" plumage. It is certainly true that individuals in "partial male" plumage, such as those showing full wattles or patches of black and yellow on the head and breast, can occur at any time of the year, including in the middle of the breeding season, and it may therefore be that all males in non-"breeding" plumage are young ones. If this is the case, then adult Schlegel's Asities have one moult per year, and the

males lack the extra refinement shown by Velvet Asities, that of having yellow friable tips on the fresh plumage.

## Habitat

The centre of distribution of the Philepittidae is the eastern Malagasy rainforests, to which all members of the family except Schlegel's Asity are restricted. All three rainforest species occur from the far south of the rainforest belt, in Andohahela, to the far north, at least to the Tsaratanana massif and, in the case of the Velvet Asity, in the east to the seasonally dry rainforests south of Daraina. None, however, occurs at Amber Mountain, an isolated rainforest block in the far north.

The Common Sunbird-asity is the only member of the family that has been recorded from the central plateau, where it has been seen a few times at Ambohitantely Special Reserve (see Movements). The Velvet Asity is found at all elevations, although it tends to be scarcer in true low-altitude forest, below about 400 m, and is apparently absent, as are the three other philepittid species, from littoral forest on sand. It is also scarcer or absent in high-altitude ericoid forest. It overlaps with Schlegel's Asity on the lower slopes of the Manongarivo massif, in the western part of the humid Sambirano region of north-west Madagascar.

The two sunbird-asities exhibit one of the few known cases of altitudinal replacement in the Malagasy forest bird community. The Common Sunbird-asity is scarce at low altitudes, often completely absent below 400 m, and certainly absent from littoral forest on sand. It may become much more common in mid-altitude forest at around 800 m, and is often abundant at around 1000-1200 m, especially where there are large numbers of epiphytic mistletoes. The species is scarcer on the drier, western slopes of massifs, and may be absent altogether from forest in deep rainshadow, such as that on the eastern side of Zahamena. The reasons for this are probably related to the lower abundance of flowering parasitic and epiphytic plants in such habitats.

In general, the Common Sunbird-asity is found in valley bottoms at up to about 1300-1500 m, where it overlaps in distribution with the Yellow-bellied Sunbird-asity, which is often found on ridgetops at the same elevation. Above this, the latter species takes over, until, from about 1600 m up to the level where the forest runs out, at 2000-2500 m, it is usually the only *Neodrepanis* present. The zone of transition depends to some extent on the height of the mountain. At Ranomafana, where summits reach only 1375 m, the Yellow-bellied Sunbird-asity is found down to about 1100 m in mossy forest 5-8 m

tall. Conversely, on the Tsaratanana massif, at 2875 m Madagascar's highest, Common Sunbird-asities ascend to 1800 m, although still in forest 15-20 m high; on this impressive mountain, Yellow-bellied Sunbird-asities occur at up to 2650 m, in the dense mossy forest.

Until very recently, the Yellow-bellied Sunbird-acity was thought to be very rare, and even possibly extinct (see Status and Conservation), but this impression seems to have been due to the lack of fieldwork in higher-altitude forest. This species is now known to be present in eastern Madagascar in almost all blocks of forest above 1600 m, and in some well below this, from Tsaratanana in the north to Andohahela in the south.

Schlegel's Asity has a completely different distribution pattern. It is fairly abundant in lowland seasonally dry rainforest on the western slopes of Manongarivo, and it occurs in similar forest to the north as far as Andavakoera; from there, it is present in seasonal and dry forest southwards to about 100 km north of Morondava. There is an additional, unconfirmed report of this species from very dry forest around Ankazoabo, well to the south of other records. The asity's preferred habitat seems to be the more humid valley bottoms, as, for example, at Ampijoroa, and forest in canyons in pinnacle karst, for instance at Bemaraha and Namoroka. While Schlegel's Asity will make short visits to flowering trees in drier parts of valley sides, it is absent from dry plateau forest on sand at

The long, decurved bill of the sunbird-asities led taxonomists to place these birds alongside the true sunbirds of the family Nectariniidae. Like that group, the species of *Neodrepanis* have two annual moults, the first of the year leading to an eclipse plumage in the male, and the second to breeding plumage. In the **Common Sunbird-acity** the two feather generations are similar on the breast and belly but the upperparts lose their iridescence in the non-breeding season. Breeding males of all species have distinctive blue or green wattles around the eye, the colour being produced by ordered arrays of collagen fibres; to date, this appears to be a mechanism for colour production unique in animals. This wattle is most prominent during the breeding season and the male can enlarge it when displaying to other individuals. During the non-breeding season it can be reduced to a narrow patch of pink skin, or lost entirely. This young **Common Sunbird-acity** (lower photo) is beginning to develop iridescence on the back and scapulars, and it shows a partly developed wattle around the eye. It is believed that the males of all four species show delayed plumage maturation.

[*Neodrepanis coruscans*, Marojejy National Park, Madagascar. Photos: Roland Seitre/Bios]

Unlike *Neodrepanis*, the genus *Philepitta* has only one moult a year, following breeding. In the **Velvet Asity**, the non-breeding coloration shows yellowish and buff fringes on most of the black feathers of the body and wing-coverts. These fringes are then worn away to show their black bases prior to courtship. The wattle in the male of this species reaches its maximum size when it is inflated during courtship display and the "horns" over the bill touch, but outside the breeding season it is almost completely absent.

Ampijoroa and Kirindy. Its easternmost limit in the Sambirano region is unknown, although it does not occur in lowland rainforest in the south of the Tsaratanana massif.

### General Habits

The two genera of asities have rather dissimilar habits. The two *Philepitta* species are the only real vegetarians of the Malagasy understorey, and their habits reflect this. Velvet Asities are often seen alone, feeding on the berries of understorey shrubs, especially those of the Rubiaceae or similar, reddish, rosehip-like fruits (see Food and Feeding), in the rainforest. They are often tame and approachable, flying only short distances when disturbed. When moving between fruiting or flowering trees, they often fly straight and fast through the understorey, out of sight. They also join mixed-species flocks, when they forage in the lower and middle storeys in a way similar to other members of such groups, and eat the occasional insect or spider. Velvet Asities sometimes feed in the canopy, up to 30 or 40 m above the ground, and they occasionally take nectar from ground-flowering plants, at which time they hop around on the forest floor with the tail cocked. Otherwise, they are, as other frugivores, rather sedentary birds, not moving much when replete, and often perching inconspicuously on slim understorey branches. They may be seen in small groups, especially in the June-September cool season, when participation in mixed-species flocks is more frequent. These parties may be family groups.

Schlegel's Asities are similar in behaviour to their congener, but they are more mobile, and are rarely seen sitting quietly in the understorey. They probably range rather more widely, owing to the lower density of potential foodplants in western dry forest. They probably feed more on nectar, too, especially during the latter part of the long western dry season, when there is very little other food available. Schlegel's Asity seems to be more of a canopy-top species than the Velvet Asity, although this may be an artefact resulting from the greater visibility in the lower canopy of its preferred habitat. It also forms small groups in the non-breeding season, and in Manongarivo it is sometimes present in mixed-species flocks at that time of the year, in June-August; this behaviour has not been remarked on elsewhere. In the central part of the west, males have been seen defending flowering trees during August, and solitary sightings are the rule except in

November-December, when males are singing; at such times, four or five males can be encountered within a few hectares.

The two sunbird-asities, as befits largely nectarivorous species, are much more active than are the frugivorous Velvet and Schlegel's Asities. They appear to be in constant motion, often perching on a branch for less than a second before buzzing away. They are also much more overtly aggressive, and will compete with, though usually lose to, true sunbirds such as the Souimanga Sunbird (*Nectarinia souimanga*) at Bakerella clumps. When faced with a human intruder, the male Yellow-bellied Sunbird-asity, in particular, is especially self-assertive: it flits around the head of the unwelcome guest, all the while calling and simultaneously displaying the prominent eye wattles, the luminous yellow throat and the brilliant blue back plumage. Human observers positioned in treetops seem to be a particular attraction for hostile reactions of this sort. Males often lean well forward on a branch, fluffing out the throat feathers and turning the head from side to side, while mobbing humans. Occasionally, an individual will spend a minute or so in calling from a single perch.

Both the asities and the sunbird-asities flick their wings, and in the case of the latter the regularity of the habit sometimes makes the bird look especially nervy. When excited, sunbird-asities also jerk the head back and forwards in an almost convulsive manner.

The two *Neodrepanis* species join mixed-species flocks, especially during the cool season, from June to September, during which period they can be seen to supplement their diet with small invertebrates (see Food and Feeding). During the warmer months, when both species feed predominantly on nectar (see Food and Feeding), they visit particularly prolific flower clumps in large numbers; 16 different individuals of the Common Sunbird-asity were collected from a single clump of flowering trees.

### Voice

The asities have rather feeble, squeaky calls. The most powerful vocalization is the song of Schlegel's Asity, given by males. It is a quiet but penetrating whistled run up and down the scale, and has a rather "rubbery" quality. This song is often delivered from the top of a canopy tree or from within vegetation, and males can be difficult to spot when singing.

Velvet Asities have less powerful calls which, owing to their squeaky character, are rather like the sounds produced by a child's

The **Common Sunbird-*asity*** shows a considerable degree of sexual dimorphism in plumage. The male is bright yellow beneath with iridescent blues and greens in the upperparts and an extensive wattle around the eye, whereas the female is a rather drab olive with only a hint of a greenish eyering. A similar degree of sexual dimorphism is shown in all four species and may be linked to a complex breeding system. *Neodrepanis* is more specialized than *Philepitta* in nectar feeding, and the long decurved bill is used for probing flowers with deep, curved nectar spurs of a range of species, though the genera *Bakerella* and *Impatiens* are particularly favoured. The sunbird-*asities* have a further adaptation for nectar feeding in that their tongues are tubular. Nevertheless, they will also take invertebrates, by probing beneath flaking bark and in dead hanging vegetation, as well as by sally-gleaning. It is thought that invertebrates may be most important during the cool season and as food for the young during the rainy season.

[*Neodrepanis coruscans*,  
Perinet, Madagascar.  
Photos: Alan Greensmith/  
Ardea]

**Velvet Asities** feed mainly on berries of understorey shrubs, with a particular predilection for those of the genus *Oncostemum*, which contain more fruit in relation to seed. The birds either feed alone or join mixed-species flocks as they move through the lower and middle storeys of the forest. The Velvet Asity is thought to be one of the principal seed dispersers for some plant genera since intact seeds have been found in their stomachs, while few other species feed on understorey fruits.

toy teddy bear. This species seems not to have a clear song equivalent to that of Schlegel's Asity, but instead has two frequent calls. One of these is a more rhythmic, repeated "whee-doo", strongly emphasized on the first syllable, and the other a long series of simple "weet" notes, often produced by lekking males (see Breeding). In addition, similar noises may be heard from foraging birds or from adults tending young.

The vocalizations of the sunbird-asities are even squeakier. The Common Sunbird-asity produces a very rapidly repeated series of hisses, very characteristic and penetrating, containing about 10-15 notes, which may grade into a more widely spaced series of similar notes. Single quiet, squeaking notes are sometimes also given when near the nest. The calls of the Yellow-bellied Sunbird-asity are much weaker, and could be mistaken for the sounds made by a tree-frog. Often, they consist of a single note, or of one note repeated at intervals of one second or longer. At times they come out at a faster rate, then amounting to a weak imitation of the call of this species' congener.

Both of the sunbird-asities produce a trilled whistle, or buzzing, in flight which appears to be caused by the relatively long and emarginated first primary (see Morphological Aspects). This feather is longer and more emarginated on males than on females, and more so in the Yellow-bellied than in the Common Sunbird-asity. It is difficult to say whether the strength of the noise produced bears any relation to these differences, although one or two observations have suggested that this may be the case. Velvet Asity males have also been reported to produce a whirring noise in flight, and a mechanical noise heard during displays may also be made by the wings.

### Food and Feeding

The *Philepitta* asities are largely frugivorous. They have been recorded eating a range of fruits, mostly reddish or orange in colour, and around 5-10 mm in diameter, which are found growing on understorey shrubs. In the case of the Velvet Asity, the most important families in this respect are Rubiaceae, Euphorbiaceae, Piperaceae and Melastomataceae. The genera include *Psychotria*, *Jasminum*, *Macaranga*, *Pittosporum*, *Chassalia* and *Oncostemum*. For at least some of these taxa, Velvet Asities are probably the principal seed-dispersers; intact seeds have been found in the stomachs of specimens, and very few other bird species in Madagascar consume understorey fruits.

The asities pick the fruits directly, while perched, or they consume them after a brief hover during which the food is detached from the parent plant in a short lunge. The larger fruits may require considerable effort to swallow.

Schlegel's Asity is less well studied. One of the few fruits which it has been noted to consume is that of a species of *Cabucala*, a member of the shrub family Apocynaceae.

During periods when fruit is abundant, Velvet Asities concentrate on *Oncostemum*, which contains more fruit in relation to seed than do other genera. When fruits of this species are in short supply, however, both Velvet and Schlegel's Asities are frequently seen feeding on other fruits, as well as on insects and at nectar-bearing flowers. For the latter, the bird's long, bifid, feather-ended tongue (see Morphological Aspects) presumably aids the collection of nectar. Most flowers thus visited are red, reddish or whitish, and those exploited by Schlegel's Asities include *Combretum*, *Albizia* and exotic *Eucalyptus*. Both the Common Sunbird-asity and the Velvet Asity have been observed feeding on the nectar of *Bakerella*, and also on a strange subterranean root parasite, probably a species of the balanophoraceous genus *Ditepalanthus*, the flowers of which open at ground level.

Velvet Asities sometimes sally-glean and flycatch for insects and other small invertebrates. This foraging method is probably practised mostly in the cool season of June-September, when fruits and flowers are at their least abundant. Furthermore, at this time of year, individuals have been observed as they ate large web-building spiders, probably of the genus *Nephila*, which had legspans of about 8 cm.

The sunbird-asities are more specialized on nectar than are the two *Philepitta* species. In November-December, they are often easy to see as they feed on the flowers of mistletoes, especially of the genus *Bakerella*, which have long, recurved nectar-bearing spurs that appear to match well the bill shape of the two *Neodrepanis* species. As mentioned above (see Morphological Aspects), however, some observations suggest that the sunbird-asities do not, in fact, insert the bill very far into these flowers, preferring instead to use the long tongue.

Other plants utilized by the sunbird-asities include *Impatiens humblotiana* of the Balsaminaceae, which is sometimes visited by considerable numbers of these birds over the course of several days, as well as *Hedychium* and *Aframomum* of the Zingiberaceae, many species of Melastomataceae, such as *Gravesia* and *Medinilla*, and equally many of Rubiaceae, including *Psychotria*, *Mussaenda* and *Gaertnera*. Even some orchids

(*Liparis*) may be used. Many of these plants have red or pink flowers.

As with the *Philepitta* asities, both species of *Neodrepanis* take insects and other invertebrates at times, probably mainly during the June–September cool season, but also as food for their young in the warm rainy season. They seek insects and spiders under flaky bark or in hanging dead vegetation, when they probe crevices and lift off small pieces of vegetation with the bill. Adults also catch small aerial insects during the warm months, possibly to feed to their young. The Yellow-bellied Sunbird-asity has been seen catching tiny flies from low bruselaceous shrubs on mountain summits, and both it and the Common Sunbird-asity will sally-glean and sally for insects when members of mixed-species flocks.

## Breeding

The Malagasy rainy season commences in November–December and ends in about April–May. This coincides broadly with the period when young birds of many species are being fed by their parents, as insects tend to be most abundant at this time. The Philepittidae also follow this pattern, with some latitudinal variation. The three rainforest species start displaying and building nests from September to November. In the northern half of the eastern rainforest, male Velvet Asities lose the friable yellow tips of their body and wing feathers often by the beginning of August, almost all of them becoming completely black by the end of September. There are records of nests with eggs in the far north on 29th August, and a fledged juvenile has been recorded from as early as 27th September, although the more normal period for fledging seems to be early October to late November. In the southern part of the species' range, nest-construction generally starts in November and December, with fledging in January–February. The timing of changes in body plumage and the initiation of breeding may also be extremely variable according to climate; the processes can be delayed by abnormally dry weather in September and October.

Information on the breeding of Schlegel's Asity and the two sunbird-asities is much more scant. The former constructs its nests between October and December. Nest dates for sunbird-asities seem to be almost as widespread temporally as are those for the Velvet Asity, with sexually active male Common Sunbird-asities collected in August and nest-building recorded in the same month, but other nests under construction during the period from then until January. The only two known nests of the Yellow-bellied Sunbird-asity were found in October and November, while recently fledged juveniles of that species have been seen in mid-November and early December, which ties in with the observation of displays in September.

All four species in the family Philepittidae seem likely to have complex and interesting breeding systems, if the strong sexual dichromatism and breeding-plumage ornaments of the males are anything to go by. The only species which has been studied in detail is the Velvet Asity, which evidently has a polygynous breeding system. The males hold small territories close to one another, these territories appearing to be display areas, rather than having any useful resources, such as food or nesting sites, contained within them. Males compete among themselves in these dispersed leks, calling and displaying in a series of ritualized manoeuvres, in order to attract the attention of females. On their territories, male Velvet Asities perform six kinds of display element. The main ones are an erect posture, in which the bird leans forward slightly over its perch, extending its neck and inflating its green and blue caruncle; a wing-flap display, whereby the male holds its wings extended horizontally, displaying the bright yellow alular spot; the horizontal posture, associated with hearing the calling of another, adjacent male; the open-gape display, whereby the bright yellow gape is shown off; and the hanging-gape display, in which the male leans all the way forward over its perch and opens the bill. In some cases, when the male asity is extremely excited, he will perform a complete perch-somersault manoeuvre, completing a turn around the branch and ending up in a "normal" posture. It appears that the horizontal, open-gape and hanging-gape displays are used be-

The songs of the all asities are generally weak and squeaky. Those of **Schlegel's Asity** are the strongest of the family, being a series of whistles running up and down the scale. The song is commonly given from the top of a tall tree or from within undergrowth. Little is known of the courtship of this species, but during one observation the male produced a series of soft squeaks, while fluffing out his breast feathers, drooping his wings, and raising his tail almost till it touched his back.

[*Philepitta schlegeli*, Ampijoroa, Madagascar. Photo: Simon Harrap]

tween males, while the erect posture and the wing-flap display are directed at females.

Displays recorded for Schlegel's Asity, while poorly documented, are rather different. In one observation, a male displayed to a female by drooping his wings and fluffing up his breast feathers, and gradually raising his tail until it almost touched the back, this sequence being accompanied by a series of quiet squeaks. There seems to be no parallel to this display in the repertoire of the Velvet Asity.

The displays of the sunbird-asities are almost as poorly known as are those of Schlegel's Asity. Indeed, the breeding of the Common Sunbird-asity remains almost completely unknown, this possibly being due to the fact that the species' nest is often located high in the subcanopy and is thus difficult to observe. At least one display of the Yellow-bellied Sunbird-asity resembles the perch-somersault of the Velvet Asity, in which the bird flips right around the perch. In the case of the sunbird-asity, however, the male begins by leaning well forward on the perch, with its chin feathers fluffed, and the caruncles and blue upperparts displayed by head-turning. As with the Velvet Asity, this display is usually directed towards other males or at intruders, such as humans. During brief observations of reactions between individuals, this display was given by a full-plumaged male, while a nearby female-plumaged bird, possibly an immature male, flapped its wings vigorously while making a twittering call; these and other individuals were then seen to chase one another around. These displays seem to be intrasexual. The only intersexual display recorded for the sunbird-asities is one in which the male gave what is termed a hunch-display, pulling his head back and lowering the bill, so that it touched the breast, while erecting the crown feathers and depressing the tail. During this display the male called vigorously, and the female touched the male's back with her bill and fluttered her wings slightly. In addition, wing-flapping is given at times by fully male-plumaged Yellow-bellied Sunbird-asities.

Surprisingly, nothing appears yet to have been published about the displays of the Common Sunbird-asity, even though it is a more numerous species.

As mentioned above, various aspects of the breeding systems and breeding behaviour of the Philepittidae have been studied in any real detail only for the Velvet Asity, and the results from investigations of this species are still preliminary. It seems likely that the Velvet Asity exhibits polygyny, with the males mating with more than one female. The polygynous breeding strategy is often found among species which feed on fruit or nectar,

The philepittid nest is thought to be constructed entirely by the female.

It is a messily woven, spherical or pear-shaped structure consisting of bamboo and root fibres suspended by filaments of grasses, bamboo or moss from the low branches of shrubs; it is generally rather similar to that of the broadbills (Eurylaimidae), to which the asities are closely related. In the **Velvet Asity**, the nest has a high proportion of moss, or indeed it can be made entirely of moss. At least two of the species create the entrance hole by poking the bill through the wall of the structure, a trait apparently unique in birds.

The hole is neatly sheltered by an overhanging porch-like structure. Nest-building takes place during November or December, coinciding with the start of the rainy season and also with the greater abundance of invertebrates, on which the young are largely fed. Male Velvet Asities are polygynous, and the female is left to raise the young alone. However, even for such a relatively well-studied member of the family, much still remains to be learnt about the breeding system employed.

[*Philepitta castanea*,

Bios]

as there may be sufficient food available for the female to bring up young on her own, thereby releasing males from the task of caring for young. Other life-history characteristics that are often linked to polygyny include delayed plumage maturation in the male; strong sexual dichromatism, including conspicuous and expensive breeding ornaments acquired by the male; lekking behaviour; and a reduced male contribution to nest-building, brooding and the care of the young. All these traits are clearly shown by Velvet Asities, while the sexual dichromatism, at least, is well marked in the other philepittid species, too.

In the case of Velvet Asities, mate selection seems to take place through males displaying in small territories that are clumped together in dispersed leks. The males call, display and show off their breeding ornaments, as described above. Females move around the area of the dispersed lek, and presumably evaluate each male according to its performance. Nest-building and incubation seem to be the responsibility of the female alone. There have been observations of more than one female-plumaged individual at a nest under construction; these apparently relate to young, female-plumaged males which harass the adult females.

Evidence from the other members of the family is more sparse. The male Schlegel's Asity accompanies the female while she is collecting nest material, and he may contribute to nest-building. The fact that several male Schlegel's Asities will sing from within a restricted area could mean that this species, too, does have dispersed leks. In addition, it may show delayed plumage maturation in males. This is indicated by the fact that, during the breeding season, males can be seen in a variety of incomplete plumages, including female-plumaged individuals with large wattles, and male-plumaged birds with the wattles either small or even lacking.

The limited information available for the sunbird-asities suggests something similar. There are certainly many examples of males of both species, in the breeding season, being equipped with incomplete breeding plumage or small wattles, and, while the sunbird-asities have no clearly defined song, they appear to use variants of their calls in social situations that could be interpreted as leks. Furthermore, only females have been recorded as constructing nests and brooding young; males collected in the breeding season all lacked brood patches. Male sunbird-asities of both species have been seen near nests under construction, and also visiting nests to feed the chicks, and male Yellow-bellied Sunbird-asities have been watched as they fed recently fledged young. In addition, males of the latter species have been observed perched near nests when females visited to feed the young, sometimes also displaying as this happened.

The sum of these observations suggests that, for all species in the family, polygyny is at least a possibility. Nevertheless, it seems likely that breeding strategies are flexible, following resource availability.

All species in the family Philepittidae construct a fairly elaborate hanging spherical or pear-shaped nest, very much in the manner of the broadbills, with suspensory filaments made out of grass, bamboo or moss, and with an entrance hole surmounted by an overhanging "porch". At least two of the four species, the Velvet Asity and the Common Sunbird-asity, make the entrance hole by poking the bill through the wall of the nest. This is the only avian family known to create the entrance hole in such a manner, instead of weaving it into the fabric of the nest.

At Ranomafana National Park, Velvet Asity nests were almost always suspended from the lowest branches of *Tambourissa obovata* trees, between 2 m and 5 m from the ground, and often over small brooks or clearings. Many nests are built entirely of moss, or with bamboo leaves as lining; some have lichenous, palm or root fibres woven into the moss, these sometimes forming a dangling tail below the nest. Nests of Schlegel's Asity are rather similar, except that, since there is little moss in the west of Madagascar, the birds supplement this with strips of bark and dead leaves, held together with spiders' webs.

The nests of the sunbird-asities are less well known, but they appear not to be very different from those of *Philepitta*. The Common Sunbird-asity is recorded as using green, drying moss and bamboo leaves, along with a few twigs and leaflets, and the nest is built at about 5 m from the ground. Yellow-bellied Sunbird-asity nests are likewise constructed of moss with bamboo lining, and

are placed 2-3 m from the ground. One such nest lacked the "porch" feature noted on other nests, but this may have been incomplete.

Almost nothing is known of the breeding biology of the Philepittidae. Clutch size is poorly documented. The Velvet Asity is reported as laying three eggs, and two eggs were present in each nest of the Common and Yellow-bellied Sunbird-asities in which eggs were found. No details are available on the length of either the incubation period or the fledging period.

## Movements

None of the members of the Philepittidae is known to undertake movements of any significance. It is possible that the Yellow-bellied Sunbird-asity makes slight altitudinal movements, responding to a decrease in abundance of food at higher altitudes during the cold, wet season of May-July or a corresponding increase in resources at lower altitudes during the same season. There are, however, very few observations of this species during that period of the year.

A more intriguing possibility is that the Common Sunbird-asity performs quite long-distance seasonal movements. This is suggested by the presence of two males at Ambohitantely Special Reserve, about 150 km from the nearest block of primary eastern rainforest, during the wet season in February 1995. The species had never before been recorded at this site, despite the fact that Ambohitantely had been the subject of fairly extensive research on its bird community. On the other hand, it is also possible that these records relate to a relict population that had not previously been detected at the site.

## Relationship with Man

All philepittids are obligate forest-dwellers, aside from making short sorties to fruiting or flowering trees a few hundred metres from the forest. This makes them vulnerable to human activity, as they depend on the existence of forest that covers land that is also needed by local people for agriculture. Apart from their extreme attractiveness, behavioural quirks and taxonomic oddity, which make them a very popular target for visiting birdwatchers and researchers, this is about the extent of their interaction with humans.

People living around the forest know these species, and local names are fairly constant between regions, suggesting that there

Although fairly common, **Schlegel's Asity** has a highly fragmented range. It is found in lowland seasonally dryforest, where it appears to be restricted to the more humid valley bottoms, deciduous forest and lowland transitional forest. These forest habitats are fast disappearing in Madagascar as a result of shifting agriculture, increased burning, and exploitation for fuel and timber for construction. However, the species is found in its greatest numbers in inaccessible ravines in calcareous karst massifs, giving it a reasonable degree of security for the present.

[*Philepitta schlegeli*, Ampijoroa, Madagascar. Photo: Simon Harrap]

Listed as Endangered in 1994 because of its limited altitudinal range, strict habitat requirements, and low population, the **Yellow-bellied Sunbird-asy** has now been found to be more widespread and numerous. At some high-altitude sites it has even been found to be relatively common. However, these forests, although largely free from the pressures of agricultural encroachment due to their remote location and unproductive soils, are highly fragmented and fire-prone.

[*Neodrepanis hypoxantha*, Andohahela National Park, Madagascar.

Photo: Frank Hawkins]

is some common knowledge of the species. This is particularly so in the case of the Velvet Asity, which is referred to as the "Asity", pronounced as "ahseetee". Information about local knowledge of the sunbird-asities and Schlegel's Asity is more difficult to come by, as the species are often difficult to see, or occur in inaccessible habitats. The sunbird-asities are often confused with the sunbirds proper, the Nectariniidae, and go under the local name of "soy", which is pronounced as "sooe".

All four philepittid species probably play an important role in forest regeneration. In this respect, the *Philepitta* asities in particular are likely to be significant dispersers of seeds, especially those of understorey shrubs, while the sunbird-asities assist in pollination. It is quite probable that the latter are responsible for a very limited amount of pollination of commercially important plant species, for instance of *Grevillea* and *Albizia* or *Eucalyptus* species growing near the forest edge.

### Status and Conservation

The Velvet Asity and the Common Sunbird-asy are both fairly common and widespread over the length of the eastern rainforest block, and, while the latter habitat is under considerable human pressure, neither species should be considered threatened. They are both probably most common in the mid-altitude rainforest belt, between 800 m and 1200 m, which is also the zone with the greatest amount of forest remaining. The Velvet Asity was noted more frequently at 1220 m and 1550 m than at 875 m in Anjanaharibe-sud Special Reserve, but was netted in approximately equal numbers at 720 m, 810 m, 1210 m and 1625 m in Andringitra National Park, and at 810 m, 1200 m and 1500 m in Andohahela National Park. It was uncommon at 400 m altitude. Common Sunbird-asities are fairly numerous in most mid-altitude forests; in the 1990s, densities in Anjanaharibe-sud Special Reserve, at 1260 m, were estimated at between 852 and 1167 individuals per square kilometre, although these figures are probably considerable overestimates, resulting from the species' habit of approaching the observer closely.

Of the two remaining species in the family, one is currently considered to be threatened and the other is Near-threatened. In 1994, the Yellow-bellied Sunbird-asy was classed as Endangered by N. J. Collar and co-workers in the official BirdLife International list, this consideration being based on the species' limited altitudinal range, apparent low population density and restricted habitat requirements. Since then, it has been shown to be much more widespread than was previously believed, and even very common in some high-altitude sites above 1200-1400 m. At Andringitra National Park, contact frequency was around 0.63 individuals per point-count site, a figure which did not differ sig-

nificantly from those for the Common Sunbird-asy at lower elevations, while densities at Anjanaharibe-sud Special Reserve were estimated at between 1900 and 6500 individuals per square kilometre; these figures, however, as those for the Common Sunbird-asy, are almost certainly gross overestimates of the true numbers. Notwithstanding the fact that the Yellow-bellied Sunbird-asy does appear to be more numerous than was formerly supposed, its conservation status remains that of Endangered. This is because it has a very small range, and one in which its forest habitat is both highly fragmented and diminishing in quality. Its current global population has been estimated very approximately at perhaps 10,000 mature adults.

The major threat to the Yellow-bellied Sunbird-asy is habitat loss resulting from uncontrolled bush fires and from agricultural encroachment. These pressures are much less marked in montane forest than in the lowlands, as montane forest grows on very unproductive soils in a relatively harsh climate. These high-lying forests do, however, burn easily and are vulnerable to fire in particularly dry years, which seem to have been especially severe in recent periods. Nevertheless, there has been no clear recent instance of any Yellow-bellied Sunbird-asy habitat being destroyed by uncontrolled bush fires. Furthermore, the species' presence in at least ten protected areas should aid its future survival.

Schlegel's Asity is considered Near-threatened owing to its very fragmented distribution and its presence in highly threatened habitats such as western Malagasy deciduous forest and lowland transitional rainforest. These two habitats are being very rapidly reduced in surface area, mostly for the purposes of shifting cultivation, the consequences of which further diminish the size and quality of the habitats. In addition, not only are dry forests within this species' range subject to burning and cattle grazing, but their timber is also exploited by local people for fuel and for use as construction material. Conservation activities aimed at reducing these pressures are under way, but the social issues, particularly lack of land tenure, increased immigration, and the use of fire as a means of protest, are immense and very difficult to manage. Fortunately for Schlegel's Asity, it is found at its highest levels of abundance in naturally protected forests, in ravines in calcareous karst massifs.

PLATE 3

Family PHILEPITTIDAE (ASITIES)  
SPECIES ACCOUNTS

Genus *PHILEPITTA* I. Geoffroy Saint-Hilaire, 1838

1. Velvet Asity

*Philepitta castanea*

French: Philépitte veloutée German: Seidenjala Spanish: Filepita Aterciopelada

**Taxonomy.** *Turdus castaneus* Statius Müller, 1776, Madagascar. Monotypic.  
**Distribution.** Rainforest belt in E Madagascar, from Manongarivo and Tsaratanana S to Andohahela.

**Descriptive notes.** 14-16.5 cm. Plump, rounded, almost tailless, with short, slightly decurved bill, short legs. Adult male breeding plumage, acquired through loss of yellow tips of body and wing-covert feathers, is black except for a yellow patch on marginal underwing-coverts and on alula, sometimes a few yellow fringes on head; wing and tail feathers usually dark brown; a large, bright pale green supra-orbital wattle, extending into a horn over base of bill, wattle with a narrow blue line over eye; eyes dark brown; bill black, gape yellow or grey; legs and feet dull greenish-olive. Non-breeding adult male has most feathers (especially wing-coverts, breast and belly feathers) tipped yellow; vestigial wattle, dull flesh in colour. Adult female has dark olive-green upperparts, a few paler feathers over ear-coverts; ear-coverts darker olive-green, marked with a pale creamy stripe originating at base of bill; moustachial stripe similar to ear-coverts in coloration; tail and wings brown with olive tinge, wing feathers fringed yellow-green; below, pale yellow-green or off-white, streaked darker olive, belly and vent clearer yellowish-green with streaks less conspicuous; eyes dark brown, bare circumorbital skin dull olive; bill black, narrow yellowish or pink gape-line, dull yellow gape; legs and feet olive. Juvenile is very similar to adult female; subadult male shows varying amounts of black plumage, acquired during 2nd calendar-year. Voice: Weak squeaky calls; rhythmic, repeated "whee-doo", first syllable strongly stressed; also long series of "weeet" notes, often by lekking males.

**Habitat.** Primary rainforest, adjacent degraded and secondary rainforest, and forest edge; visits flowering or fruiting trees, e.g. stands of guava (*Psidium cattleianum*), close to forest edge or in adjacent second growth. Often in areas of open understorey in valley sides and bottoms. Recorded

at low and middle altitudes; probably most common between 600 m and 1400 m, scarce below 400 m and above 1600 m, and absent from montane sclerophyllous forest.

**Food and Feeding.** Mostly frugivorous; eats small (c. 5-10 mm diameter) red or orange fruits of understorey shrubs; most important families are Rubiaceae, Euphorbiaceae, Piperaceae and Melastomataceae, and plant genera include especially *Oncostemum*, also *Psychotria*, *Jasminum*, *Macaranga*, *Pittosporum*, *Chassalia*. Seasonally, also takes nectar from terrestrial and shrub-layer species, e.g. *Bakerella*. Arthropods taken occasionally. Forages in canopy and down to lower levels; hops on forest floor. Fruits picked directly from perch, or plucked during brief hover. Joins mixed-species flocks, mostly in Jun-Sept.

**Breeding.** Laying in Sept-Dec; from end Aug in N. Apparently polygynous. Dispersed leks in which each male has small, non-resource-based territory; erect posture and wing-flap display directed at females, with horizontal, open-gape and hanging-gape displays and flipping around perch used between males. Nest built by female, an elongated sphere made of moss and bamboo, entrance hole adorned with a "porch", suspended from lowermost branches of low tree (very often *Tambourissa*) at 2-5 m, often over a stream or path. Clutch 3 eggs; male takes little or no part in incubation or care of young.

**Movements.** None known.

**Status and Conservation.** Not globally threatened. Fairly common in most remaining E rainforest blocks, and not immediately threatened. Also capable of tolerating some habitat degradation. Probably a principal agent in dispersal of seeds of understorey shrubs. Occurs in all protected areas within its range, e.g. Ranomafana, Andringitra and Andohahela National Parks, Anjanaharibe-sud Special Reserve, and Perinet Special Reserve.

**Bibliography.** Albiguac (1970), Benson *et al.* (1976-1977), Dee (1986), Delacour (1932a, 1932b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Goodman & Andrianarimisa (1995), Goodman *et al.* (1997), Greiner *et al.* (1996), Hartlaub (1877), Langrand (1995), Milne-Edwards & Grandidier (1875, 1885), Milon (1951), Milon *et al.* (1973), Morris & Hawkins (1998), Pether (1969), Prum (1999), Prum & Razafindratsita (1997), Prum, Morrison & Ten Eyck (1994), Prum, Torres *et al.* (1999), Rakotomanana (1998), Rakotomanana & Hino (1998), Rakotonomenjanahary & Hawkins (2000), Rand (1936), Razafindratsita (1995), Safford & Duckworth (1990), Salvan (1972), Sinclair & Langrand (1998), Thorstrom & Watson (1997), Yamagishi *et al.* (1997).

2. Schlegel's Asity

*Philepitta schlegeli*

French: Philépitte de Schlegel German: Gelbbauchjala Spanish: Filepita de Schlegel

**Taxonomy.** *Philepitta schlegeli* Schlegel, 1867, Madagascar. Monotypic.

**Distribution.** N, NW & W Madagascar, from Andavakoera in N, S to c. 70 km N of Morondava in W.

**Descriptive notes.** 12.5-14 cm. Small, round, short-tailed, with short bill and legs. Adult male breeding has head mostly black, brilliant apple-green wattle extending in front, below and in two lobes

behind eye, wattle with cobalt-blue band passing through eye and on to lower lobe; upper mantle and underparts brilliant yellow, back olive-green; wings and tail duller, browner, with pale olive fringes; eyes dark brown; bill blackish, gape orange-yellow, sometimes also a narrow yellow gape-line; legs and feet slate-grey. Male non-breeding plumage olive-green above, variable amounts of creamy streaking on crown, nape and ear-coverts, and on collar, usually some black on lores, crown or ear-coverts; wings and tail brownish, variable olive-green fringes on outer webs, brighter yellow area on bend of wing; dull yellow on throat, mottled darker on breast and upper belly, brighter clear yellow on undertail-coverts and vent, bare parts as breeding, but with dull fleshy yellow orbital ring, no yellow gape-line. Female is very similar to non-breeding male, but lacks black on head. Subadult or moulting male often has intermediate plumage between female and breeding male; can have entirely female-like plumage and large, fully formed wattle, or have no wattle and yet be similar in plumage to breeding male. Voice. Male song a quiet but penetrating whistle of c. 7-9 notes, rising and then falling; quiet squeaks in display.

**Habitat.** Lowland seasonally dry rainforest, W deciduous forest and karst canyon forest; locally also in W dry forest, usually adjacent to more humid or sheltered areas. Sea-level to 800 m.

**Food and Feeding.** Largely frugivorous, especially in rainy season; fruits include those of *Cabucala* (Apocynaceae). Probably increasingly nectarivorous and insectivorous in late dry season, when fruits are scarce; visits mostly red, reddish or whitish flowers, including *Combretum*, *Albizia* and exotic *Eucalyptus*. Often forages in canopy, sometimes descending to understorey. Usually singly; also in small groups in non-breeding season, in Jun-Aug, when sometimes joins mixed-species flocks.

**Breeding.** Little known. Nest-building in Oct-Dec. Probably polygynous; breeding strategy possibly variable in response to resource availability. Possibly dispersed male leks; male display with drooping wings, fluffing of breast feathers and tail-cocking recorded. Globular nest with entrance "porch" built by female, possibly assisted by male, constructed of moss with bark or leaf strips, held together with spiders' webs, suspended from low branch of understorey tree. Clutch size not documented; no other information.

**Movements.** None known.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in West Malagasy Dry Forests EBA and East Malagasy Wet Forests EBA. Rather scarce in most areas. Commonest in moist and transitional forests of Sambirano region of NW, and especially in karst canyons in W, e.g. Namoroka and Bemaraha, where forest habitat is naturally protected; only local in W dry forests, mainly in limestone areas. In Sambirano, gold-mining has destroyed certain areas of moist forest and also resulted in increased immigration into region, leading to further clearance of forest for subsistence farming. Dry-forest habitats within species' range have suffered severe deterioration through burning and cattle grazing, as well as from utilization of wood for fuel and building materials. Very patchy distribution over much of its range, making any genetically significant contact between populations very unlikely.

**Bibliography.** Appert (1996), Benson *et al.* (1976-1977), Dee (1986), Delacour (1930a, 1932a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Goodman & Andrianarimisa (1995), Goodman *et al.* (1996), Hawkins (1994), Langrand (1995), Milne-Edwards & Grandidier (1875, 1885), Milton (1951), Milton *et al.* (1973), Morris & Hawkins (1998), Rakotonomenjanahary & Hawkins (2000), Rand (1936), Robertson (1995), Sinclair & Langrand (1998), Stattersfield & Capper (2000), Tingay & Gilbert (1999), Yamagishi *et al.* (1997), Young (1995).

## Genus *NEODREPANIS* Sharpe, 1875

### 3. Common Sunbird-asyity

#### *Neodrepanis coruscans*

**French:** Philépitte souimanga

**Spanish:** Filepita-suimanga Común

**German:** Langschnabel-Nektarjale

**Other common names:** Sunbird Asity, Wattled Sunbird-asyity, Wattled Asity/Sunbird, (Wattled) False Sunbird

**Taxonomy.** *Neodrepanis coruscans* Sharpe, 1875, Madagascar. Monotypic.

**Distribution.** E Madagascar, from at least Tsaratanana in N, S to Andohahela.

**Descriptive notes.** 9.5-10.5 cm. Tiny, short-tailed, with remarkably long and decurved bill, short legs. Adult male breeding has bright blue head with large, mostly sky-blue wattle around eye, orbital ring green, and a bright green line extending from the wattle along base of bill below nostrils, bright blue above nostrils; upperparts dark blue, iridescent blue fringes on feathers of back, inner wing-coverts and rump; primaries narrowly fringed yellow; underparts dull yellow with olive wash or streaking; eyes brown; bill blackish; legs and feet dark brown. Non-breeding male is olive-green on head and back (often some iridescent blue

feathers on rump), often with vestigial bright blue eye wattle; darker tertiaries and wing feathers edged paler green; underparts dull yellow, streaked olive, somewhat brighter yellow on flanks; bare parts as breeding male. Female similar to non-breeding male, but lacks vestigial wattle and blue rump feathering, and even duller below, brightest on flanks, suffused with olive on breast. Juvenile has slight pale fringes on wing-coverts, initially has pale pink base of bill. Voice. Single quiet, squeaking notes; also very rapidly repeated series of hisses, c. 10-15 notes, sometimes grading into more widely spaced series.

**Habitat.** Canopy and subcanopy of primary mid-elevation and lower montane rainforest. Sea-level to c. 1500 m, locally to 1800 m; scarce or often absent below 400 m.

**Food and Feeding.** Mostly nectar, from a wide range of pink, red and white flowers, including *Bakerella*, *Impatiens humboldtiana*, *Hedychium* and *Aframomum*, many species of Melastomataceae (e.g. *Gravesia*, *Medinilla*) and many of Rubiaceae (e.g. *Psychotria*, *Mussaenda*, *Gaertnera*); some orchids (*Liparis*) may be exploited. Also insects, either caught in aerial sallies or removed from dead leaf clumps or from crevices. Joins mixed-species flocks, especially during Jun-Sept.

**Breeding.** Little known. Nest-building recorded in Aug-Jan. Possibly polygynous. Displays not documented. Female builds suspended ovoid nest with entrance "porch", made of moss, leaf strips and few twigs, c. 5 m from ground in subcanopy. Clutch 2 eggs; chicks fed by both sexes.

**Movements.** Unclear; some evidence of seasonal presence in high-plateau forests at Ambositantely. Otherwise, seems present at most sites throughout year, although short movements in relation to nectar abundance could be expected.

**Status and Conservation.** Not globally threatened. Fairly common and widespread. Although restricted to primary forest at middle and lower montane levels, this habitat is the most abundant natural formation in Madagascar. Occurs in several protected areas, e.g. Ranomafana National Park, Anjanaharibe-sud Special Reserve, and Marojejy Strict Nature Reserve.

**Bibliography.** Andrianarimisa (1995), Benson *et al.* (1976-1977), Dee (1986), Delacour (1932a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Goodman *et al.* (1997), Hartlaub (1877), Hawkins *et al.* (1997), Langrand (1995), Milne-Edwards & Grandidier (1875, 1885), Milton *et al.* (1973), Morris & Hawkins (1998), Rakotonomenjanahary & Hawkins (2000), Safford & Duckworth (1990), Salomonsen (1934, 1965), Salvan (1972), Sinclair & Langrand (1998), Thorstrom & Watson (1997), Yamagishi *et al.* (1997).

### 4. Yellow-bellied Sunbird-asyity

#### *Neodrepanis hypoxantha*

**French:** Philépitte de Salomonsen

**Spanish:** Filepita-suimanga Ventrigualda

**German:** Kurzschnabel-Nektarjale

**Other common names:** Yellow-bellied Asity, Small-billed Asity/False Sunbird

**Taxonomy.** *Neodrepanis hypoxantha* Salomonsen, 1933, east of Antananarivo, eastern Madagascar. Monotypic.

**Distribution.** Patchily along rainforest belt of E Madagascar.

**Descriptive notes.** 9-10 cm. Tiny, short-tailed, with long, decurved bill, short legs. Breeding male has black crown, neck, mantle, scapulars, wing-coverts, tertiaries and rump, all widely edged iridescent royal blue; black wing feathers and tail; bright yellow underparts; very large, carunculated wattle around eye, lime-green towards centre, mid-blue around edge; wattle extends forward nearly to bill, and a mid-green line extends along base of bill to nostril, blue above nostril; eyes brown; bill blackish; legs and feet dark brown. Non-breeding male has olive-green from crown to rump, a few iridescent blue feathers, especially on rump, narrow paler olive

tertiary fringes; wing feathers and tail darker olive-brown; vivid deep yellow underparts, brightest on throat and breast, slightly washed olive on flanks and towards vent; a vestigial blue eye wattle, often just a blue spot behind or over eye. Female similar to non-breeding male, but lacks iridescent feathering and vestigial wattle. Juvenile resembles female; after post-juvenile moult, has paler fringes on greater and median wing-coverts, and duller yellow breast and belly. Voice. Single squeaky note, sometimes repeated at intervals of 1 second or more, occasionally faster.

**Habitat.** Canopy and subcanopy of montane rainforest; areas with shrubby vegetation preferred. Occurs from c. 1100 m, mostly from 1400 m, to upper limit of arborescent vegetation, locally to 2650 m. Becomes more common at transition from mid-altitude forest to moss forest.

**Food and Feeding.** Mostly nectar, taken from wide variety of plant genera; feeds chiefly from pink, white and red flowers, especially parasitic ones, including *Bakerella*, also *Impatiens humboldtiana*, *Hedychium*, *Aframomum*, Melastomataceae (e.g. *Gravesia*, *Medinilla*), Rubiaceae (e.g. *Psychotria*, *Mussaenda*, *Gaertnera*). Also some insects, caught by sallies from tops of low shrubs, or taken from dead leaf clumps or under loose bark. Moves very actively in canopy and subcanopy. Sometimes joins mixed-species flocks, especially during Jun-Sept.

**Breeding.** Nesting observed in Nov-Jan. Probably polygynous. Displays by male include hunch-display with head retracted, bill lowered to touch breast, crown feathers erected and tail depressed, also wing-flapping, also flipping around perch. Female builds suspended ovoid nest with entrance "porch", largely of moss and leaf strips, 2-3 m from ground in the mid-storey. Clutch 2 eggs; chicks fed by both sexes.

**Movements.** Possibly some altitudinal movement downslope in May-Jul cold season; otherwise, none known.

**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in East Malagasy Wet Forests EBA. Has very small and severely fragmented range, within which extent of rainforest habitat appears to be diminishing. Its habitat, however, is not so threatened as are many in Madagascar. Recent observations indicate that this species is less rare than was previously believed, and even common in some places; probably occurs in all intact forest above c. 1200 m. Present in at least 10 protected areas, e.g. Ranomafana, Andringitra, Andohahela and Mantadia National Parks, Anjanaharibe-sud Special Reserve, and Perinet Special Reserve. Total population size not known, but thought possibly to number 10,000 or more adults. Main threat is habitat loss from uncontrolled bush fires and agricultural encroachment. Although higher-altitude forests in E Madagascar are more remote than other forest types, and therefore the last to be cleared for agriculture, they are nevertheless extremely fragmented, and also vulnerable to fire; in dry years, some of this species' habitats suffer burning.

**Bibliography.** Anon. Class AVES  
Order PASSERIFORMES  
Suborder EURYLAIMI  
**Family PITTIDAE (PITTAS)**

- Small to medium-sized birds with strong bill, short to medium-short tail and long legs, many with colourful plumage.
- 15-29 cm.

- Afrotropical, Oriental and Australasian Regions.
- Forest.
- 1 genus, 30 species, 91 taxa.
- 9 species threatened; none extinct since 1600.

### Systematics

The DNA-DNA hybridization experiments carried out by C. G. Sibley and J. E. Ahlquist led those authors to conclude that the pittas formed a monophyletic group, with a single common ancestor. Although there appears to be no reason why this should not be so, the identity of the family's closest relatives has been a matter of debate. In 1975, J. J. Morony and colleagues placed the pittas between the plantcutters (Phytotomidae) of South America and the New Zealand wrens (Acanthisittidae). Four years later, E. Mayr placed the Pittidae between the plantcutters and the asities (Philepittidae) of Madagascar, an approach adopted also by H. E. Wolters, but with the asities coming before the pittas and the plantcutters after them. Sibley and Ahlquist's work, however, suggests that the pittas, while not too far removed from the New Zealand wrens, are most closely related to the broadbills (Eurylaimidae) and the asities, of which they are a sister-group. This finding has gained general acceptance, and it is worth pointing out, incidentally, that more recent authors have also combined the asities with the broadbills in a single family.

There are no fossil records of pittas, but the dusky to blackish stripes which are present on the feathers of most members of this family (see Morphological Aspects) may suggest that they derive from more streaked ancestors. It is possible, therefore, that the pittas, like most bird species with striped plumage, may once have lived in more open habitats. The greatest diversity of species is found in South-east Asia, suggesting that the Pittidae originated in that area and from there radiated westwards into India and Africa, and southwards and eastwards to Sumatra, Borneo, the Philippines, New Guinea and Australia. The Afrotropical species may have colonized that region at an early stage, as the structure and pigmentation of the green feathers have retained several primitive characters not found in any other pitta species. In addition, the African Pitta (*Pitta angolensis*) has what appears to be a unique display (see Breeding).

In his *Systema Naturae* of 1766, Linnaeus placed the Indian Pitta (*Pitta brachyura*) in the crow family (Corvidae), naming it *Corvus brachyurus*. Ten years later, Statius Muller, following Brisson and Buffon, placed it in the thrush family (Turdidae), a group with which the pittas do, indeed, have much more in common, including, for instance, long legs and certain aspects of the moulting strategy and feeding behaviour. This superficial resemblance to the thrushes is alluded to in the pittas' colloquial names of "jewel-thrushes" and "ant-thrushes" (see Relationship with Man).

The pittas became more widely known from 1863, when D. G. Elliot published his magnificent work entitled *A Monograph of the Pittidae*. The book has 32 colour plates, most of them painted by the author himself. Elliot restricted the generic name *Pitta* to those species having a comparatively long, graduated tail, and used *Brachyurus* for the remaining, very short-tailed species.

Less than two decades later, in 1880/81, J. Gould, in his unfinished monograph of the family, moved the Indian Pitta from the genus *Brachyurus* to *Pitta*, in addition to which he adopted the generic name *Cyanopitta* (a subgenus in Elliot's 1870 revised edition) for the Azure-breasted Pitta (*Pitta steerii*) and also followed other authors in recognizing seven further genera. Thus, he placed the three longer-tailed species, the Banded (*Pitta guajana*), Bar-bellied (*Pitta ellioti*) and Gurney's Pittas (*Pitta gurneyi*), in the genus *Eucichla*; the Ivory-breasted Pitta (*Pitta maxima*) in *Leucopitta*; the Blue-banded Pitta (*Pitta*

The **Garnet Pitta** forms a superspecies with the **Graceful Pitta** (*Pitta venusta*), the two differing in plumage, voice, altitudinal preferences and the tail length. The taxonomy of the form *ussheri* of northern Borneo is somewhat contentious: some authors believe that differences in plumage features and voice, combined with a lack of interbreeding where the ranges overlap, suggest it merits separation as a distinct species. However, *ussheri* is not so very distinctive, and some cases of hybridization have been recorded, so on present knowledge it seems best to retain this form as a race of the Garnet Pitta.

[*Pitta granatina ussheri*, Sabah, Borneo. Photo: Frank Lambert]

The **Red-bellied Pitta** is the most widely diversified species in the family, with a total of 24 subspecies recognized, 13 in the Philippines and Wallacea and 11 in New Guinea, Australia and the South Pacific islands. Some authors believe the subspecies *dohertyi* of the Banggai and Sula Islands to be a full species, on the basis of plumage differences, a narrower bill and an apparently distinctive call. Close examination of a large sample of all 24 subspecies, however, showed that *dohertyi* was no more convincing a candidate for splitting than several of the numerous island races of the Red-bellied Pitta. Further investigations, including molecular-genetic analysis, may show that not only *dohertyi*, but perhaps also other distinctive forms such as *novaeahibernicae*, should be given full species status, but meantime it probably makes more sense to continue to regard all as races of the Red-bellied Pitta.

[*Pitta erythrogaster novaeahibernicae*, New Ireland.

Photo: William S. Peckover]

*arquata*) and the Garnet Pitta (*Pitta granatina*) in *Phoenicichla*; the Hooded Pitta (*Pitta sordida*) in *Melanopitta*; the Red-bellied Pitta (*Pitta erythrogaster*) in *Erythropitta*; the Blue-headed Pitta (*Pitta baudii*) in *Iridipitta*; and the Giant Pitta (*Pitta caerulea*) in *Gigantipitta*. Moreover, Gould followed current trends in including within Pittidae the Lesser Melampitta (*Melampitta lugubris*) from New Guinea, although that species has long been considered to be unrelated to the pittas, instead now being treated as a close relative of the birds-of-paradise (Paradisaeidae). Just seven or eight years after Gould's work appeared, however, P. L. Sclater recognized only three genera of pittas when he produced the 14th volume of the *Catalogue of the Birds in the British Museum*: *Anthocincla* for the short-legged Eared Pitta (*Pitta phayrei*); *Eucichla* for the three species with a relatively long, graduated tail; and *Pitta* for all of the remaining members of the family. In his second monograph of the pittas, which appeared during 1893-1895, Elliot followed Sclater's treatment.

As long ago as 1816, L. J. P. Vieillot had been the first person to use the generic name *Pitta* for the whole family, though at that stage the vast majority of the more distinctive species had yet to be discovered. Wolters, in his 1975-1980 checklist, preferred the polygeneric approach, recognizing the six genera *Hydrornis*, *Iridipitta*, *Eucichla*, *Leucopitta*, *Anthocincla* and *Pitta*, together with some subgenera. The DNA-DNA hybridization experiments carried out by Sibley and Ahlquist suggested that further subdivision of the family might indeed be justified, although only four species were included in the analysis undertaken by those scientists. A thorough molecular-genetic study of pittas remains to be done. The other major recent investigation of the relationships of the Pittidae was conducted in 1987, by R. J. Raikow, who examined the hind-limb musculature of two pitta species to infer the phylogenetic relationships of the family among the Old World suboscines.

The pittas do appear to form a homogeneous group. It has been suggested that the splitting of the family into different genera would detract from nomenclatural stability, leading to a certain amount of confusion. It may indeed be best to postpone any such generic splits until sufficient information becomes available for them to be made with a reasonable degree of confidence. Even so, the treatment of the Eared Pitta remains controversial. This poorly known species differs from all other members of the family in having short legs, a slightly decurved and slender bill, and a very long hind claw, and it is strongly argued that it merits separation in the monotypic genus *Anthocincla*. The little information that exists about its displays and its feeding habits also reveals some apparently unusual features.

Historically, the number of pitta species recognized by different authors has varied from 24 to as many as twice that figure. In the late nineteenth century, Sclater mentioned 48 species in his catalogue, one more than did Elliot in the second edition of his monograph. Checklists published during the last three decades of the twentieth century, on the other hand, gave much lower totals, of fewer than 30, with Morony and colleagues recognizing only 24 species of pitta. Needless to say, all these figures should be taken in the context of their times: before the advent of the formal recognition of subspecies in trinomials, it was natural that the species concept be somewhat narrower.

In the second half of the 1990s, two major works on the Pittidae were published. The first of these, by F. Lambert and M. Woodcock, listed 32 species of Pittidae, whereas J. Erritzoe and H. B. Erritzoe, two years later, recognized 30 species. The discrepancy is due to differing opinions on the treatment of the taxon *dohertyi*, found in the Banggai Archipelago and the Sula Islands, to the east of Sulawesi, and of the form *ussheri*, living in north Borneo. Sibley and B. L. Monroe, in their world checklist, treated *dohertyi* as a full species, distinct from the Red-bellied Pitta. Lambert and Woodcock referred to apparent plumage differences

Most members of the family Pittidae have spectacularly beautiful plumage colours and in some aspects of their behaviour they recall thrushes (Turdidae), this giving rise to their early name of "jewel thrushes". Their colourful plumage has endeared them to aviculturists, while birdwatchers too are attracted by the birds' beauty and also relish the challenge of seeking these often shy and secretive species in dark and dense forest habitats. Pittas are fairly unusual among birds of the forest understorey in not showing generally dull plumage. Their bright, contrasting colours, most commonly green, blue, red, red-brown and buff, tend to be in sharply outlined patches. Several species have shining azure-blue on the wing-coverts and rump. As these two males of different **Banded Pitta** subspecies demonstrate, the head-pattern can be very striking, here through the combination of dark crown and mask set against yellow and whitish, with orange on the supercilium of the lower bird, of the race *irena*, which Gould called "one of Nature's living jewels". Other eye-catching features are the white on the wing-coverts and the barred underparts. The latter markings are also shared by the Banded Pitta with two other pittas, all three species also having a relatively long, graduated blue tail. Pittas tend to have the brightest colours on their underparts, while the upperparts are usually rather duller.

The **Blue Pitta** may form a group with the poorly known and apparently rare *Schneider's Pitta* (*Pitta schneideri*) and the **Giant Pitta** (*P. caerulea*), all three having blue upperparts, including rump and tail. The Blue Pitta also shows disjointed barring mainly on the underparts, and has a bold dark mask, while there is an area of bright orange on the hindcrown and nape. Standing by its well-concealed domed nest, this male Blue Pitta shows the fairly heavy, slightly downcurved bill typical of pittas, and also particularly noticeable are the long, rather robust legs with long powerful toes, well adapted to the birds' terrestrial habits. Interestingly, leg colour varies considerably between individual pittas.

exhibited by the the "Sula Pitta", in particular the head pattern and darker feather centres on the upperparts, as well as possible vocal differences. In an examination of long series of specimens of all subspecies of the Red-bellied Pitta, however, *dohertyi* was found to be no more distinctive than any of the numerous other island races of this highly variable species, which also displays great geographical variation in vocalizations. Future research may indicate that *dohertyi* and perhaps other distinctive forms of the species, such as *splendida*, *rubrimucha* and *novaehibernicae* may merit species rank, but for the time being it is thought wiser to include all of them as subspecies of the Red-bellied Pitta.

The main reasons put forward for treating *ussheri* as a separate species from the Garnet Pitta are differences in appearance and vocalizations, and the fact that the two appear not to interbreed in areas where their ranges meet each other. Although they do, admittedly, exhibit a certain dissimilarity in several plumage features and calls, the differences are considered to be too small to be utilized for species recognition. Moreover, hybrids between *ussheri* and the nominate subspecies of the Garnet Pitta are well documented, even though some authors have queried the identification of some of these specimens. Whether hybridization can be considered as adequate evidence for conspecificity is another matter, and opinions on this vary widely. Again, until more information becomes available, it seems better to continue to treat the form *ussheri* as a subspecies of the Garnet Pitta. Some authors have regarded it as a race of the closely related Graceful Pitta (*Pitta venusta*), but that differs considerably in the colours of the body and upperwing-coverts and in the length of the tail. In this connection, it is perhaps relevant to mention that the supposedly all-yellow chick of *ussheri*, mentioned by some recent authors, does not belong to this taxon at all (see Morphological Aspects).

Owing to the fact that relevant studies of the pittas are both very few in number and incomplete in coverage, the taxonomy within the family is currently based primarily on external morphology, especially colour patterns. Although this provides a somewhat superficial parameter, it enables the 30 members of the family to be divided into seven groups. The first of these contains just one species, the highly distinctive Eared Pitta, which, in addition to its slender, decurved bill and its short legs with a very long hind claw, is largely rufous in colour. Its head pattern,

with a black crown and nape, and with very long, black-edged whitish feathers on each side of the crown, resembling horns or ears, is also very distinctive. In addition, a series of behavioural features argue strongly in favour of returning this species to its former position in the monospecific genus *Anthocincla*.

The second group comprises the Blue-naped Pitta (*Pitta nipalensis*), the Blue-rumped Pitta (*Pitta soror*) and the Rusty-naped Pitta (*Pitta oatesi*), all of which have rather dull plum-

**Blue-rumped Pittas** are typically shy and secretive and it is not surprising that the species has been rarely photographed in the wild. It forms a well-marked group with the **Blue-naped Pitta** (*Pitta nipalensis*) and the **Rusty-naped Pitta** (*P. oatesi*). These three species share rather drab brownish plumage, a rather faint broken breastband and similar vocalizations. The Blue-rumped has the crown, nape and mantle variably tinged bluish-green, in line with its generally dull colours, but the rump and uppertail-coverts are bright blue and strikingly conspicuous in flight.

[*Pitta soror tonkinensis*.  
Photo: Roland Seitre]

An Indonesian endemic and one of the smaller members of the family, the **Elegant Pitta** is found in five different subspecies on many islands in the southern part of the archipelago. The bird portrayed shows the classic large eye, strong bill, and large feet on long strong tarsi characteristic of most Pittidae. The pale lateral crownstripe contrasts strongly with the otherwise velvety black colour of the head. Neither the large black central belly patch typical of race *concinna*, nor the green distal half of the tail and blue rump, can be seen in this photo, but some scarlet shows on the lower belly and undertail-coverts. The white band across the primaries, conspicuous in flight, is completely concealed.

[*Pitta elegans concinna*, Poco Ndeki, near Kisol, west Flores, Lesser Sundas. Photo: Frank G. Rozendaal]

age, with a broken breastband, and utter very similar vocalizations. They are considered to form a close-knit group. The next three, Schneider's Pitta (*Pitta schneideri*), the Giant Pitta and the Blue Pitta (*Pitta cyanea*), form a group of species having blue upperparts, the first two also possessing a broken breastband, while the Blue Pitta is intermediate between those two and the next group, the barred pittas. This next group, which includes the Banded, Bar-bellied and Gurney's Pittas, is characterized by the possession of comparatively longer tail feathers, which are graduated in length. The fifth group contains a single species, the Blue-headed Pitta, with dark purplish-blue underparts. One of two members of the family restricted to Borneo, it appears to have no close relatives, but its blue crown and its red-brown back indicate some affinity with Gurney's Pitta. All of the species in these last four groups, as well as the very different Eared Pitta, exhibit sexual dimorphism, and their juveniles, so far as these are known, have cryptic plumage colours and patterns.

The five species which make up the sixth group differ markedly from one another in general appearance, but all have some red on the underparts. The relationship between the almost black Superb Pitta (*Pitta superba*) of Manus, the largest of the Admiralty Islands, and the Ivory-breasted Pitta of the north Moluccas, is still unclear; both of these restricted-range species are rather large to very large and have a black head and upperparts, while the ivory-coloured breast and flanks of the second species are unique among the Pittidae. They show no sexual dimorphism, and the young differ in plumage from the adults only in being duller. The three other species in this group are the Blue-banded Pitta, the Garnet Pitta and the Graceful Pitta, the last two of which form a superspecies. In contrast to the Superb and the Ivory-breasted Pittas, they are very small and have weak, rounded and notably curved wings, suggesting the shared acquisition of a sedentary lifestyle. There are no external differences between the sexes, and the young are cryptically coloured.

All of the family's remaining 14 species have green or greenish upperparts, and all but one of them have red on the underparts. Together, they form the final and largest group. This contains the only migratory pittas, and includes what are generally the most common members of the family. All of these species are sexually monomorphic, and in all except two the

juveniles look like duller versions of the adults. The group also includes the only Afrotropical representatives of the Pittidae, the superspecies formed by the African Pitta and the Green-breasted Pitta (*Pitta reichenowi*); both have prominent "horns" created by elongated feathers at the side of the nape. Two others, the Azure-breasted Pitta and the Whiskered Pitta (*Pitta kochi*), are confined to the Philippines, where the more widespread Hooded and Red-bellied Pittas also occur. The Azure-breasted is the only member of the family to have pale azure underparts, but its black head reveals a certain affinity with the

Most pittas are sedentary, but **African Pittas** of the large race *longipennis*, with pointed wingtips, regularly migrate as much as 2000 km. Apart from the size difference, *longipennis* has less red on the underparts than *pulih*, and usually a more uniformly coloured supercilium, as well as violet on the rump and wing-coverts; it lacks the greenish sheen on the underparts of *pulih*. Displaying African Pittas stand erect, with the cinnamon-buff breast feathers ruffled and the elongated supercilia raised at the rear, giving the impression of "horns", as also occurs in the closely related Green-breasted Pitta (*Pitta reichenowi*).

[*Pitta angolensis longipennis*, Haroni-Rusito confluence area, east Zimbabwe. Photo: P. J. Ginn]

Lacking the bold, bright colours of many other pittas, being largely a rather cryptic rufous-brown, the **Eared Pitta** is likely to be confused only with immatures of other pitta species. It is also notable for the rather short legs, long and slender bill and very long hind claw. The proposal to place it in a separate monotypic genus, *Anthocincla*, is gaining considerable support, and is backed up by some features of its behaviour, though other authors assert that in aspects such as voice and breeding biology it is fairly typical of *Pitta*. Male head patterns vary considerably among individuals.

The most striking feature is the elongated and pointed feathers, usually white with black scaling, which protrude to the rear as "ears" or "horns".

[*Pitta phayrei*,

Park, Thailand.  
Photo: Bernard van Elegem]

Hooded Pitta. Some of the Hooded's twelve subspecies have the top of the head and the nape red-brown, a feature shared by the Whiskered Pitta, the only species with olive-brown upperparts, and also by the Red-bellied Pitta. The Whiskered and the Red-bellied are closely related, and their juveniles have cryptic plumage coloration.

The next seven of the "greenbacks" have a variably black side of the head and a buffish breast. The Indian Pitta and the Fairy Pitta (*Pitta nympha*) are so similar in appearance that they were until a few years ago considered by many authors to be

conspecific, despite the fact that they have geographically discrete distributions and, in addition, a number of distinctive features that are easily visible in the field. The Blue-winged Pitta (*Pitta moluccensis*) and the Mangrove Pitta (*Pitta megarhyncha*), on the other hand, have partly overlapping ranges, but they differ more markedly in ecology and behaviour and are separated from each other by habitat. Despite this slight overlap, all four may be considered to form a superspecies. Three of the five subspecies of the Elegant Pitta (*Pitta elegans*), which is distributed over many small islands in Wallacea, have a blue or bluish tinge on the pos-

Among the sexually dimorphic pittas are the three blue-backed species, including the large and robust **Giant Pitta**. In this species, the most obvious difference between the sexes is in the upperparts, blue in the male but rufous-brown in the cryptically coloured female, though her tail is blue like the male's. The male also shows a black hindcrown, nape and necklace, which in the female are reduced to a black-scaled greyish crown.

terior part of the buff supercilium, and all five have a black crown, whereas the crown of the Noisy Pitta (*Pitta versicolor*) of coastal east and north-east Australia is red-brown. The Black-faced Pitta (*Pitta anerythra*) of the Solomon Islands is the sole member of this large group that has no red on the belly, but it does have red-brown on the crown or hindcrown; a further characteristic is its very short and curved wings, suggesting a poor capacity for flight. The last of the 14 "greenbacks", the beautiful little Rainbow Pitta (*Pitta iris*) of north Australia, has a scarlet belly and a chestnut lateral crownstripe, but most of the head and underparts are black and the green of the back has a glistering olive-green sheen. The relationships of the Elegant, Noisy, Black-faced and Rainbow

Pittas are uncertain, but the four are probably best considered as forming a superspecies.

While the above groupings should be regarded as somewhat tentative, they do offer a practical working hypothesis when examining the systematics of this family. Different arrangements have been preferred by some authors. For example, Sibley and Monroe considered the Superb, Ivory-breasted and Hooded Pittas to form a superspecies, and this treatment was followed by Lambert and Woodcock. The morphological differences that exist between those three pittas, however, seem too great for such a close relationship to be regarded as acceptable.

Their solitary and sedentary habits render most pittas poor colonizers of remote islands. Some island forms do exist, however, and these often represent borderline cases between what could be considered subspecies and what could be treated as species. Island subspecies, geographically isolated from the main area of a species' distribution, exhibit more rapid and discontinuous differentiation than do mainland forms, in which clines extending over great distances are common. It seems inevitable that new molecular-genetic studies, and investigations using other new forms of technology, will lead to changes in both the sequence and the taxonomic relationships of the Pittidae, and to the upgrading of some of the taxa of polytypic pitta species. The best examples of the latter involve the Red-bellied Pitta, with 24 subspecies, and the Hooded Pitta, with twelve subspecies; as alluded to above, many of the races inhabiting various islands lying between continental Asia and New Guinea are so distinctive that they may well represent several separate species. The case of the Red-bellied has been discussed above. In the Hooded, the races *goodfellowi*, *novaeguineae*, *meffoorana* and *rosenbergii*, encompassing the region of New Guinea, would possibly be better treated as forming a separate species. To date, however, the lack of specimen material and of field studies makes it advisable to await the results of future research before jumping to conclusions.

Finally, it may be of some interest to note that, as with a great many avian taxa, two species of Pittidae bear scientific names that are clearly the result of misunderstandings. The Banded Pitta was given the specific name *guajanus* because the species was erroneously thought to come from the Guianas, in South America. Similarly, the Blue-winged Pitta carries the species name *moluccensis*, despite the fact that it has never been recorded in the Moluccas.

Even brightly coloured adult pittas can be difficult to see in the darkness of the rainforest and, as might perhaps be expected, the inexperienced juveniles gain protection from cryptically coloured, streaked and spotted, brownish plumage. While adults of all the 24 subspecies of the **Red-bellied Pitta** have blue on the breast and a red belly, juveniles are dull brown above, with a whitish throat and buffish-white underparts; there is darker brown or black mottling on the breast and the only blue is on the rump and tail.

[*Pitta erythrogaster inspeculata*, Talaud, off north-east Sulawesi. Photo: Frank Lambert]

The **Indian Pitta** is one of a group of 14 species in the family with cryptically coloured green or greenish upperparts. It inhabits scrub jungle, sometimes with bamboo, semi-cultivation, and deciduous and evergreen forest, mostly in lowlands and foothills, where the deep leaf litter provides optimal foraging habitat. During migration, if forced to seek shelter in poor weather or just after arrival, especially in misty conditions, birds are attracted by lights and often come into gardens, sometimes even entering buildings.

[*Pitta brachyura*, Borivali National Park, Maharashtra, India. Photo: I. Kehimkar/DPA]

Characteristic pitta habitat comprises a rich forest understorey, leaf litter and the proximity of flowing water. Throughout most of its considerable range, the **Red-bellied Pitta** inhabits rainforest or monsoon forest with secondary growth, usually below 1000 m. In Sulawesi, it occurs in the lowlands and up to at least 120 m, being particularly common on volcanic soils in forest with dense rattan palm. In places, this species co-exists successfully with the Hooded Pitta (*Pitta sordida*), the Red-bellied Pitta being more often found in hills.

### Morphological Aspects

Diagnostic characters of the Pittidae include a strong, slightly curved bill, a stout body, a short tail, and a strong and long tarsus with a long anterior and posterior plate, similar to that of the typical thrushes. The feet are moderately long to long, with the first digit generally the longest or of the same length as the third; the second and fourth digits are much shorter and are similar in length. The claw of the hind toe is always the longest, and the claw of the fourth toe is most often smaller than that of the second. The short or shortish wing has ten primaries, the outermost of which is long and reaches almost to the tip of the wing, and the tail has twelve short feathers. Pittas vary in size, from 15 cm to 29 cm, and also in weight. The smallest females of the Hooded and Red-bellied Pittas weigh as little as 42 g, whereas males of the largest species, the Giant and Ivory-breasted Pittas, can have a weight of almost 210 g.

Those pitta species having distributions which cover a broad range of latitudes conform with "Bergmann's Rule", which states that selection favours a large body at higher, cooler latitudes or altitudes. This is especially noticeable in the case of the Noisy Pitta of Australia, where the small subspecies *simillima* of the northern Cape York Peninsula has an average wing length of 122 mm, compared with 130 mm for the nominate race living in the cooler areas farther south. More surprisingly, there is also a difference in clutch size (see Breeding).

In the majority of species, the plumage of both sexes is variegated and colourful. Green, blue, red, red-brown and buff dominate, but many other shades are often present. Most of the colours are bright and occur in sharply demarcated patches, which are relatively uniform and unmarked. The juvenile plumage is brownish, with streaking and spotting.

It is worth drawing attention to an apparently erroneous account which has appeared in print before. This relates to a "recently hatched chick" which was "entirely yellow", and which was said to have been collected from a nest of the Garnet Pitta of the race *ussheri* in north Borneo. If this were the case, then this taxon would be unique among the Pittidae in having a chick plumage that was totally different from that of the adult. Furthermore, the museum label attached to the adult Garnet Pitta accompanying the chick states that the two were shot together, but makes no mention of a nest; in addition, the chick's flight-feathers are fully grown, so that it cannot have been newly hatched. The picture becomes even more clouded when it is realized that the staff at

the Natural History Museum, Tring, UK, where the specimens are held, have been unable to determine the species of bird to which the yellow chick belongs, so the two have simply been placed together for the sake of convenience.

Pittas are ground-dwelling birds inhabiting forest or semi-forest, where they feed on insects, worms, snails, small vertebrates and even vegetable matter and fruits (see Food and Feeding). Most birds of the forest understorey have dull-coloured plumage, which provides them with camouflage in this habitat, whereas bright colours are often associated with life in the sunlit tree-tops. The pittas are, therefore, a somewhat surprising exception to this general rule. Despite the fact that they inhabit dark

When disturbed, in contrast to many other pitta species which prefer to hop away into dense cover, the **Ivory-breasted Pitta** tends to take flight quite easily, often whirring away for some distance.

Calling birds also perch regularly in trees, often on bare branches in the lower canopy, up to 20 m above the ground. Territorial disputes involving much calling, sometimes in long bouts from adjacent trees, also take place in the lower canopy, and this is presumably analogous to the song-duels of other passerines.

thickets of the forest floor, many members of this family are highly colourful, which perhaps explains why they are so popular among ornithologists. The brightest colours are usually on the underparts, but with glittering and lustrous blue and blue-green on the wings, rump and uppertail-coverts. These so-called "badges", however, can be concealed, those on the wings being covered by the long scapular feathers and that on the rump being hidden by the wings, which, together with the back, are mostly of a green or brown shade. Because most predators approach from above, this is a good strategy. Surprisingly, most fieldworkers report how difficult it is to find pittas in the darkness of the rainforest, where only here and there do the rays of dazzling sunlight filter through the dense vegetation.

Only four species have conspicuous colours on the head and upperparts, visible to potential predators. These are Schneider's, Giant, Blue and Blue-headed Pittas. Although most members of the family are countershaded, four species have darker underparts. Gurney's Pitta has a broad black band across the middle of the breast and belly, while the Blue-headed Pitta has the middle of the breast shining black, with the breast sides, belly and flanks dark blue-violet, a colour which in most lights appears black. The Superb Pitta is glossy black on the underparts, with the central lower breast, belly and undertail-coverts bright red. The Rainbow Pitta of Australia is even more extensively dark below, having the underparts almost entirely black, except for a scarlet lower belly and undertail-coverts.

Cryptic coloration in both sexes is found only in the Eared Pitta, but is also present to some degree in the females of the ten other sexually dimorphic species, examples of which include the Blue-naped and Rusty-naped Pittas, the Giant and Blue Pittas and the Banded and Blue-headed Pittas. As would be expected, all juvenile pittas exhibit cryptic coloration to varying degrees.

It is possible that the colour badges are also selected for through female choice, as being indicative of male fitness, or better condition. Sexual selection and natural selection often pull in opposite directions, the first increasing the attractiveness of the males, and the second favouring aspects of security such as manoeuvrability and cryptic coloration. The way in which these behavioural and ecological trade-offs are linked with plumage coloration among the pittas could provide an interesting subject for study.

A great majority of pittas, 24 of the 30 species, have a white wing patch of variable size, visible on most species only when the wings are spread. In the darkness of a jungle, where white will flash like a bright light, this is perhaps a mechanism designed to startle potential predators for the fraction of a second which can make the difference between life and death. It is notable that the three weak fliers with particularly short, rounded and curved wings, the Blue-banded, Garnet and Graceful Pittas, do not have any white in the wings.

Most pittas have short and rather rounded wings, but the four migrants in the family, the African, Indian, Fairy and Blue-winged Pittas (see Movements), all show more pointed wingtips. It is significant that the most successful pittas are the migratory species or subspecies, found over large geographical areas, and com-

*Endemic to Borneo, the Blue-banded Pitta is found in a wide altitudinal range, but most frequently at higher elevations. It generally favours mixed dipterocarp forests, and in Sabah it can be found in forest where bamboo is dominant. It is often encountered in areas with fallen tree trunks, and the birds often call from fallen trunks or flee to them when disturbed. Pittas tend to be inactive during the hottest part of the day, often standing on one leg on a root or fallen branch, and they can be difficult to spot at such times in dark areas of the forest.*

Demeulemeester]

*The Mangrove Pitta is indeed a mangrove specialist, occurring along coasts, at deltas and in tidal parts of rivers. Its posture and massive bill, well shown in this photo, strongly suggest a very small perched heron (Ardeidae). Birds will leap from root to root to escape, but also frequently fly when disturbed and may then be mistaken for a kingfisher (Pelargopsis). Feeding largely on crabs, the Mangrove Pitta will forage on the seaward side of mangroves, even perching on moored boats; it will cross open mud between vegetation patches and also use drier areas nearby.*

Pittas are active during the day, but will usually rest during the hottest period. For nocturnal roosting, birds normally use a perch in a bush or tree, low down or as much as 3-5 m up. Looking like some exotic flower or fruit, this colourful **Garnet Pitta** has adopted a remarkable ball-like posture with the plumage markedly ruffled and the head tucked into the back feathers. A similar roosting posture has been described for other pitta species.

[*Pitta granatina ussheri*,

Area, Sabah, Borneo.  
Photo: Michael & Patricia  
Fogden]

mon over most parts of their distribution. The Fairy Pitta is the only exception to this; as it makes long ocean crossings, it may be vulnerable to the vagaries of the weather (see Movements, Status and Conservation).

Like most monogamous birds, pittas do not exhibit any special male morphological ornaments or other features for display purposes. Fourteen species are sexually monomorphic, and seven others show only minor differences between the sexes. Only nine species are strongly dimorphic, these being the Eared Pitta, and the Blue-naped, Schneider's, Giant, Blue, Banded, Bar-bellied, Gurney's and Blue-headed Pittas. Judging from what is known for other bird families, the glittering blue areas on the wings and rump are presumably used for threatening opponents during territorial defence and to impress the female during courtship. Should a site be occupied, an unsettled male probably conceals most of his epaulets without challenging the owner.

There is striking variation in the colours of the legs and feet of pittas. In the Blue-headed Pitta, for example, they range from grey-blue to horn-coloured or to flesh-coloured, in the Garnet Pitta from plumbeous to purplish-brown or blue, in the Whiskered Pitta from brownish to slate-blue, in the Elegant Pitta from pale flesh to reddish-brown, and in the Rainbow Pitta from flesh-coloured to silvery grey or reddish-grey. Since most of these descriptions are taken from expedition skins, for which the bare-part colours are recorded soon after the death of the bird, it would seem reasonable to assume that most of them are accurate. In 1982, N. Burley and co-workers pointed out that the tarsi and toes of many birds are often brightly coloured, and that colourful tarsi could well be important in the mate-choice component of sexual selection because they might reflect individual differences in levels of circulating testosterone and/or carotenoid pigments. Varying iris colour, as seen in the Blue-winged Pitta, may also provide information about the male's physical condition. Interpretation of this is somewhat speculative, although it appears that sexual selection is causally related to the divergence of populations. This is a profitable field for future research.

An extremely interesting plumage feature, and one which is unique to the Pittidae, is the dusky to black stripes exhibited by many individuals of nearly all members of the family. This feature was first described in full in 1998, by Erritzoe and Erritzoe. The dusky markings take the form of arrow-shaped streaks in the middle of the feathers, and appear most often on the upperparts; they are normally visible only on the upper surface of the feather. The pointed end is anteriorly oriented, but non-pointed streaks also occur. Typically, the dark stripes are present on the blue or

blue-green wing patches and rump, those on the rump always being glossy blackish and, unlike the dusky stripes, also visible on the underside of the feather. It would therefore be more correct to speak of dusky and glossy black streaks. These markings are never found on the head, chin, throat, thighs, undertail-coverts or tail; nor are they present on the flight-feathers, although streaks are sometimes seen on the tertials. They can be found on green, olive-green, blue to blue-green and azure feathers. Four species, the Green-breasted, Azure-breasted, Hooded and Red-bellied Pittas, also have similar streaks on the underpart feathers. The smallest dusky stripes recorded are for the Red-bellied Pitta, on which they measured  $2.3 \times 0.8$  mm, while the largest, on an Elegant Pitta, had dimensions of  $18.4 \times 3.4$  mm.

Pittas commonly assume an upright posture when alert, as demonstrated by this **Blue-winged Pitta**.

Some species are also known to adopt a similar pose during certain displays, and this is probably more widespread than currently known. Ivory-breasted Pittas (*Pitta maxima*) calling on the ground adopted almost penguin-like erect postures and, following a courtship chase, a pair of Hooded Pittas (*P. sordida*) similarly stretched up to their maximum height, before relaxing into the normal posture, bobbing their tails up and down and calling. In display on territory boundaries, the well-studied Rainbow Pitta (*P. iris*) moves from an initial upright posture to perform slow bowing movements in which the breast nearly touches the ground.

[*Pitta moluccensis*.  
Photo: Roland Seitre]

The number of individuals of a species exhibiting this feature varies hugely, from 4% in the Mangrove Pitta to 68% in the Noisy Pitta. Similarly, the number of stripes varies considerably from one individual to another. Within the species, it seems that the most colourful forms have the most stripes. Furthermore, dusky streaks are slightly more frequent on males than on females, and are rarely found on juveniles.

Significant differences exist between populations in the prevalence of dusky streaking. For example, of a collection of Blue-winged Pittas taken in Myanmar: from Amherst, there were 26 specimens with streaking but only one without; from Bankasoon, 18 streaked, seven unstreaked; and from Tenasserim, 13 streaked, eleven unstreaked. Again, for the Rainbow Pitta, about 60% of 23 skins taken at different sites exhibited dusky streaks, yet around Darwin, Australia, not one with streaking was found amongst 89 ringed birds, all of which were carefully examined.

Rainbow Pittas undergo a post-nuptial moult, and it seems likely that this applies to all members of the family. In the case of the Ivory-breasted Pitta and the Suberb Pitta, the flight-feathers are moulted descendantly, starting with the innermost primary and gradually proceeding outwards. In connection with moult, an unusual and rather mysterious phenomenon occurs among the pittas. Some individuals, having completed the moult into adult plumage, reveal a complete absence of feathers on the head and neck, or have these areas nearly bare, with only the feather pins showing. Nineteen such examples, involving nine species of pitta, have been found in museum collections, and one instance has been described in the literature. There is no explanation for this most curious phenomenon, which has otherwise been reported only by D. W. Snow for a population of Eurasian Blackbirds (*Turdus merula*) at Oxford, England, in the 1950s.

## Habitat

Most pittas inhabit tropical forest, semi-forest and scrub, and many species have a penchant for living near watercourses. The typical habitat is forest with a rich, moist understorey and a ground cover of leaf litter, frequently on limestone and in areas with steep-sided ravines. The Noisy Pitta is often found in moist forest with moss-covered rocks, and the Rainbow Pitta frequently occurs in monsoon forest with vine thickets and in eucalypt (*Eucalyptus*) forest. Many species, among them the Eared, Blue-naped, Blue-banded, Indian and Blue-winged Pittas, frequent bamboo thickets, and some, including the Giant and Garnet Pittas, can be found in swamp-forest and other marshy habitats. The Mangrove Pitta is, as its name suggests, a mangrove specialist.

Ten species of pitta occupy lowland rainforest, one of the world's most threatened habitats. Lowland-forest specialists include Gurney's Pitta, with an altitudinal limit of 160 m, the Rainbow Pitta, recorded at up to 400 m, and the Garnet Pitta, which ascends to 500 m. The Blue-headed and Ivory-breasted Pittas can be found at slightly higher elevations, occurring at up to 600 m, and the Bar-bellied Pitta and the Black-faced Pitta to 800 m. Although the Superb Pitta has not yet been recorded above 100 m, it probably does also occur at higher elevations. In common with a number of other lowland-rainforest specialists, Gurney's Pitta is believed to be on the brink of extinction as a result of serious loss of its habitat (see Status and Conservation). Two other pittas, the Blue-winged and Mangrove Pittas, are also lowland species, but the former can be found at higher altitudes outside the breeding season. The Fairy Pitta has been recorded at up to 1300 m in Taiwan, but it generally lives at lower levels in Japan.

The remaining members of the family inhabit forest from the foothills up to about 1800 m, and a few reach even higher altitudes. The Blue-naped Pitta and the Red-bellied Pitta have been found at 2100 m, the Whiskered Pitta at 2300 m, Schneider's Pitta at 2400 m, and the Rusty-naped Pitta at 2600 m.

The highest elevation at which a pitta has been recorded is 2980 m. The species involved was a Blue-winged Pitta, found in the province of Gansu, in central China, and presumed to have been a vagrant.

Spreading and flicking of the wings and similar movements of the tail are typical of an active pitta in a variety of contexts. The effect of such movements, demonstrated here by a **Rainbow Pitta** and a **Garnet Pitta**, is enhanced by their revealing the scintillating blue on wings and rump and the normally concealed white primary-patches. In antagonistic encounters, some species combine wing-spreading with crouching, and wing-flicking with a leaping display. Flicking and raising the wings to vertical, combined with alarm-calls, serves to distract predators.

## General Habits

Pittas are mainly diurnal birds, requiring daylight in order to locate their often hidden prey. They are generally shy birds and are, therefore, very difficult to observe, but an imitation of their calls will usually bring them into view. When disturbed, many species prefer to hop into thickets rather than taking flight. Outside the breeding season most of them are solitary, and even young pittas seem rarely to have much close contact with their parents except when they are hungry. This strategy not only seems to offer them better protection against enemies, but also makes the transmission of parasites and pathogens less likely. There are, nonetheless, some records of migratory species occurring in loose flocks.

A close-up view of a pitta undisturbed in its natural surroundings is a memorable experience. If the bird is active, it can make

**The Mangrove Pitta**, a highly vocal but shy species, gives a loud, fluty double call, which has been rendered as "hhwa-hwa", "tu-will" or "tae-laew", and resembles the call of the closely related

Blue-winged Pitta (*Pitta moluccensis*).

The Mangrove Pitta generally calls from a treetop or from the canopy of mangroves, but there is a surprising report of a bird calling from its nest, which is not known for any other pitta. Like many other species, the Mangrove Pitta is especially vocal in the morning and evening, but it will also call during the day and at night, particularly by moonlight.

[*Pitta megarhyncha*,

Photo: Morten Strange]

itself very conspicuous through the flicking of its wings and tail, displaying the glittering blue colours on the wings and rump, and revealing the flashing white wing patch (see Morphological Aspects) as it moves sturdily in long hops and turns over dead leaves for the insects beneath them. Such a view makes an unforgettable impression on the observer, and it is no surprise that pittas are among the most popular and sought-after bird groups among birdwatchers. During the hottest part of the day, however, they frequently remain inactive, often standing on one leg on a root or a fallen branch, and at such times they can be very difficult to detect in dark areas of the forest.

Although the pittas are, in the minds of most people, associated with a terrestrial lifestyle, they roost most often in trees.

Pittas are strongly territorial. The African Pitta maintains a territory of 3000-3600 m<sup>2</sup>, while that of the smaller Rainbow Pitta can extend to over 10,000 m<sup>2</sup>. They also exhibit marked site-fidelity. E. C. Stuart Baker, for example, reported that a pair of Blue-naped Pittas returned in ten successive years to breed at the same spot under some small bamboo clumps close to his house in India. Even migratory species such as the Hooded and African Pittas are reported to hold stable territories in their non-breeding quarters.

In an observation of territorial defence involving two Elegant Pittas, the birds were described as standing less than a metre apart, each one with the neck outstretched and swaying from side to side very slowly and deliberately. The Rainbow Pitta has a bowing display, given when two territory-holding birds meet along a boundary. From an initial upright posture, the pitta bows stiffly and slowly downwards until its breast nearly touches the ground, the whole display taking five to 20 seconds and being accompanied by a sound resembling the purring of a cat. It then hops a short distance before repeating the show. It has been suggested that this ritual helps in the establishing and maintaining of territories. The same behaviour has also been recorded for the Red-bellied, Hooded and Garnet Pittas. If threatened, the Rainbow Pitta spreads its wings while in an upright posture and gives its alarm call. In similar circumstances, the African Pitta stands "on tiptoe", with the breast puffed out, and with the projecting buff feathers of the rear supercilia erected to resemble "horns".

A real fight has, however, been reported only once in the wild. Two male Giant Pittas in a primary forest in north Borneo

were heard calling for a period, the observer judging that they were probably at least 100 m from one another. Not long after, however, one of the males was seen chasing the other down a slope in the forest, the pursuit being briefly interrupted as the two scuffled on the forest floor, where they were locked together; the chase then continued as the two males flew at low level farther down the mountain.

Pittas appear to bathe regularly, and observations of captive individuals reveal that many members of the family indulge frequently in this activity. After each bath, they spend much time in preening the feathers. The African Pitta has been reported as using soil on its bill when preening. Sun-bathing has been observed

**Indian Pittas** call mostly at dawn and dusk from a bush or tree, sometimes on the ground. A clear double whistling "wheet-tieu" or similar is given, sometimes mixed with harsh, high-pitched sounds. As can be seen here, the calling bird adopts an upright posture with the head thrown back; after a short bout of calls it may move to another vantage point.

The Indian Pitta is migratory and also calls on its wintering grounds, initially using a harsh "jazz" or "hizz" call, presumably to establish a territory there. Its habit of calling early and late in the day in winter quarters earned it the Tamil name which translates as "six o'clock bird".

[*Pitta brachyura*,  
Royal Chitwan National  
Park, Nepal.  
Photo: Otto Pfister]

for the Hooded Pitta, the Noisy Pitta and the Rainbow Pitta, and the last of those has also been seen anting, for which purpose it exploited green ants.

Despite a frequent reluctance to fly, the majority of the pittas are capable fliers. The African Pitta, for example, flies low, fast and straight, and the flight of the Fairy Pitta has even been compared with that of a kingfisher (Alcedinidae).

## Voice

The vocalizations of pittas have often been described as "song". It may, however, be better to refer to them as calls, following the definitions of the two terms by B. Campbell and E. Lack. Those authors stated that songs are long and complex, and produced by males in the breeding season, whereas calls are short and simple vocalizations produced by both sexes at all times of the year.

All pitta vocalizations are easy to imitate. This is because they are short, monosyllabic or disyllabic, fluty or whirring notes,

and a few of them even sound like human-language words. In the case of the Rainbow Pitta, at least, both sexes call, although the male does so more often than the female.

That calling is an important component in competition between males is demonstrated by the fact that it is easy to attract and capture territory-holding male pittas by using playback of their recorded calls. In the breeding season, pittas can be highly vocal, especially in the period before egg-laying. Apart from the Mangrove Pitta, which often calls loudly while brooding, they are silent when on the nest. During the rest of the year, most species call in the early morning and the late evening. In cloudy weather, however, the Indian Pitta often calls throughout the day, and the Blue-winged and Mangrove Pittas call at night when the moonlight is bright and clear.

A rather characteristic aspect of the behaviour of the Pittidae is that the call of one individual will frequently stimulate others to respond, and the forest may resound with pitta calls during vocal periods. This is particularly noticeable in the case of the Ivory-breasted Pitta of the north Moluccas, which combines calling with a kind of grouping behaviour. Three to six of these birds will call and then slowly make their way towards one another, moving either on the ground or from branch to branch. When vocalizing from the ground, the birds often move after each call, but they can remain still for extended periods when calling from the trees. During bouts of calling, pittas on the ground assume an erect posture almost like that of a penguin (Spheniscidae).

Territorial calls uttered by pittas exhibit a wide interspecific variation. Gurney's Pitta, for example, gives an explosive "lilip", whereas the Superb Pitta utters a "coo-coo", the Mangrove Pitta "tu-will" and the Elegant Pitta "wea-tea hea". The territorial call of the Eared Pitta sounds like a yelping dog, while that of the Ivory-breasted Pitta is very like a human wolf-whistle. An observer on Borneo who hears cries like those of a baby may well be witnessing the vocalizations of the beautiful Blue-headed Pitta, and in Australia both the Noisy Pitta and the Rainbow Pitta can produce a cat-like purring sound. The most famous verbal rendition of a pitta call, however, must surely be the "walk to work" or "want a watch" of the Noisy Pitta.

The alarm call is the most uniform vocalization among the Pittidae. It is variously described as "keew", "keow", "kriaih", "skyeew" or "eeyow", although the Rainbow Pitta also gives a

*Usually calling from a perch at 2-7 m above the ground, the **Superb Pitta** most commonly gives a clear, rather deep and melodious whistle rendered "hwouw whouw" or "coo-coo". Calling duets occur with, for example, a double whistle every 4-5 seconds. Pittas are known sometimes to call with open wings, as this **Superb Pitta** demonstrates, and there are also reports of wing-flicking in this situation.*

[*Pitta superb*, Manus, Admiralty Islands, off northern New Guinea. Photo: Guy Dutton]

*Pittas forage mainly on the ground, frequently in leaf litter, where they will sweep or flick the dead leaves aside with sideways motions of the bill, or sometimes scratch among leaves with the feet. While most foraging is carried out in the undergrowth, both the **Rainbow Pitta** and the **Indian Pitta** (*Pitta brachyura*) have been recorded on lawns, presumably in search of worms. There are further records of pittas foraging where wild pigs had churned up the soil, and in the nest mounds of a scrubfowl (*Megapodius*). A captive Hooded Pitta (*P. sordida*) was recorded digging in soft soil for earthworms, and it seems likely that wild pittas also do this.*

[*Pitta iris*, Howard Springs, Darwin, Australia. Photo: Martin Hale]

"yeeaaach" call, the Banded Pitta emits a "krrr", and the Rusty-naped Pitta utters a "tchick" note.

### Food and Feeding

Earthworms (Annelida), when available, are probably the food items taken most frequently by pittas, although, in the dry season, the worms move deeper into the soil and thus become inaccessible. Snails are also a common food of the members of the family. Otherwise, the diet is composed predominantly of a variety of invertebrates, such as termites (Isoptera), ants, Orthoptera, beetles, bugs (Hemiptera), lepidopterans, centipedes (Chilopoda) and spiders, which the pittas come across in the leaf litter, but small skinks (Scincidae), snakes, lizards and frogs have also been reported. A number of species, including Schneider's Pitta, the Indian Pitta, the Garnet Pitta and the Noisy Pitta, are known to consume vegetable food on occasion. Further, the Rainbow Pitta takes fruit from *Carpentaria* palms, and a Red-bellied Pitta is reported to have taken newly planted seeds of maize (*Zea mays*).

Pittas feed in a thrush-like manner in the darkness of the forest floor, brushing or sweeping aside dead leaves with sideways motions of the bill. Typically, the two sexes of a pair feed in loose association with each other, separated by distances of 5-30 m; it seems probable that the act of keeping somewhat apart helps to avoid the risk that one individual's potential prey will be disturbed by its partner. Two species, the Indian Pitta and the Rainbow Pitta, have been observed feeding quite openly on lawns in town parks, where they were probably taking earthworms.

As long ago as 1934, J. Delacour described the way in which a captive Hooded Pitta sought worms by digging with its bill into the soft earth. Since that time, numerous observers have reported seeing pittas with an earth-soiled bill. The suggestion that these birds may be able to locate prey by smell is supported by a study of the olfactory system undertaken by B. G. Bang and S. Cobb, who found that an Indian Pitta had the largest olfactory ratio among 25 different species of Passeriformes which they examined.

Besides having a keen sense of smell, the pittas are notable for their use of inanimate objects in the environment. Eight members of this family have been recorded as utilizing a stone as an "anvil" on which to smash snail shells, and it is likely that this behaviour, which is very like that of the widespread Song Thrush

(*Turdus philomelos*) in the Palearctic, is practised by more pitta species. The Rainbow Pitta employs a branch or root for the same purpose.

Several authors have cited a published report in which it is stated that a captive Hooded Pitta ate approximately its own weight in food every day. This claim does, however, seem very unlikely and is not supported by other studies. Observations of a captive Fairy Pitta, for example, revealed that, during a period of 51 days, it consumed only about 10% of its body weight per day. Moreover, a study in Borneo found that wild-living Garnet Pittas consumed about 30% of their own weight every day. Bearing in mind the more sedate lifestyle of captive birds, it is probable that the daily amount of food consumed by most species of pitta is in the region of 15% to 30% of the body weight.

### Breeding

Pittas are monogamous, with both parents caring for the young, a breeding system shared with about 90% of all avian species. They are solitary breeders, and defend their territories against intruders. Extra-pair copulation has never been reported for this family, despite two decades of DNA analysis in which it has been shown to be common among many monogamous birds. Several of the rarer species exist at such low densities that extra-pair copulation is not likely to take place, although it would not be surprising if future research revealed this behaviour to occur in areas where pitta populations are dense.

Information on breeding biology, some of this derived mainly from captive birds, exists for 27 of the 30 members of the family. The nest and eggs of Schneider's, Azure-breasted and Whiskered Pittas have never been found. In the case of the last of those three, however, the local inhabitants of the Philippine island of Luzon, to which this pitta is confined, report that the species lays its eggs in February in a nest which is situated either on the ground or low down in a bush.

The breeding season is typically synchronized with the onset of the rainy season. The Superb Pitta, confined to Manus, in the Admiralty Islands, is presumably an exception, because rainfall on the island is distributed evenly throughout the year; as a result, other bird species living on Manus breed in all months of the year, except during the period when they are moulting. There

The **African Pitta** tends to forage in shade, standing motionless in the leaf litter, especially near ant and termite mounds, and watching for prey, sometimes after sweeping leaves aside; it may then move to a new site 1-2 m away. If prey is spotted, the bird lunges forward to seize the item in its bill.

Pittas have been observed to leap up to snatch flying termites or to take a spider from its web in similar fashion.

Examination of the olfactory system indicated that pittas are able to locate prey by smell. Snails are regularly eaten by many species, the shells being smashed on a stone "anvil" or on a root or branch.

[*Pitta angolensis pulih*,  
15 km from Oban,  
east Nigeria.  
Photo: A. P. Leventis]

Pittas take a wide range of invertebrate prey, mainly adult and larval insects, earthworms, snails and slugs, but also other molluscs, crustaceans, spiders, centipedes and millipedes. Insects consumed include crickets, bugs, cockroaches, termites, butterflies and moths, flies, ants and beetles. Small numbers of vertebrates are also eaten, including lizards, snakes, frogs and "field mice". The Indian Pitta (*Pitta brachyura*) commonly takes beetle larvae from manure and fly maggots from human faeces when foraging near villages. Vegetable matter has been recorded in the diet of certain pitta species, for instance green plants, seeds, berries and fruit. It has, however, been suggested that any fruit taken from the ground is ingested primarily because it is infested with adult or larval insects. Little is known of the diet of wild **Fairy Pittas**, but a captive bird took ground beetles (Carabidae) up to 25 mm in length, while persistently ignoring one 40 mm long.

[*Pitta nympha*,  
Shi-Men Dam,  
Tao-Yuan, Taiwan.  
Photo: Huang Win-shing]

are several reasons why the vast majority of pitta species time their breeding activities to coincide with the wet season. Arthropod abundance usually increases a week or two after the stimulus provided by a fall of rain, and earthworms, which are the most important food items for pitta chicks, are easier to find after rain. In addition, the vegetation becomes denser during the wet season, thereby offering more protection and camouflage for the nest and young.

Relatively little is known about the breeding displays of the pittas. What is perhaps the most interesting behaviour in this respect has been recorded in Africa. At the beginning of the breeding season, the African Pitta perches on a more or less horizontal branch, some 5 m or so above the ground, from where it jumps about 25-40 cm into the air, fluffing out the red belly feathers as it does so, before parachuting down to the branch again. During this display, in which the bird performs two or three jumps per minute, or sometimes more, it produces a curious, partly mechanical sound which could be transcribed as "prrrouut". Between bouts of displaying, the pitta will fluff out the feathers of its underparts and swing sideways. No similar breeding displays have been recorded for any other members of the family.

Courtship behaviour remains very poorly known, although some displays related to this stage of the breeding cycle have been described for Hooded Pittas in captivity. After the male had chased the female around for some length of time, both of the adults, while standing on the ground, stretched up to their maximum height and then relaxed back into the normal posture, whereupon they bobbed the tail up and down while uttering a growling call. In addition, the male often crouched low while growling, and at times one of the pittas would perform wing-flicking movements while standing in front of its mate.

According to the available information, special pre-copulatory behaviour is virtually non-existent. An exception is provided by the Noisy Pitta, the female of which has been watched as she picked up some debris from the forest floor and hopped around while holding it in her bill; when the male appeared and chased her, she then stopped, and copulation followed.

Pittas are not accomplished nest-builders. In fact, they usually put together only a skimpy structure, which is very difficult to remove without causing it damage. Nest structure is one of the most uniform features within the pitta family. All those species for which the relevant information exists construct a nest resembling a flattened dome, with a side entrance. In most

cases, the nest is the size of a rugby football, and it is built very loosely, such that it is very difficult to recognize as it looks very like an agglomeration of plant remnants blown together by the wind. Several fieldworkers have reported the finding of old-looking nests parts of which have fallen off, or with the entrance hole doubled in size, yet still containing a sitting pitta. Some species, such as the Noisy Pitta, add a platform or "door-mat" of sticks, often decorated with mammal dung, at the base of the entrance hole.

The nest is often well camouflaged among vines or other vegetation, and is frequently made from the same materials as those of the surroundings, although the Blue Pitta will fly long distances in order to obtain bamboo leaves for the nest. It is usually composed of dead and skeletonized leaves, sticks, mosses and grasses, the whole structure being held together with plant fibres and fine roots. The interior cavity is lined with finer material, such as root and plant fibres, forming a neater nest cup.

Some of the Pittidae place the nest on the ground, among tree roots or fallen branches or on a dead stump, while others choose to locate it at a higher level, in the cleft or the forked branches of a tree. Many species, however, demonstrate wide individual variation in nest placement. The two African species always build in bushes or trees, suggesting that terrestrial predators are a greater problem in the Afrotropics than elsewhere. Nests situated on the ground tend to suffer greater predation than do those placed in trees or bushes, and the sitting bird, as well as the eggs and chicks, is at risk of being taken. The flexibility in nest placement shown by many pittas may mean that they are able facultatively to switch their nesting habits to adapt to the presence of an introduced terrestrial predator.

Both sexes participate in the building of the nest, but the male is often the principal labourer. Typically, the work requires two to eight days, the total time perhaps depending on the age and experience of the individual birds concerned. A new nest is probably built for each brood-rearing attempt.

Clutch size varies considerably among the members of the family. Increased predation may select for smaller brood size, as a greater concentration of helpless or inexperienced young may attract predators through their vocalizations, as also would the more frequent provisioning visits by the parents. In terms of energy expenditure, a small clutch is also less costly to replace af-

ter predation than is a bigger one. The most common clutch size is three to five eggs, but the number varies from two, as in the case of the Garnet Pitta, to up to six, as in the Blue-winged and Indian Pittas.

A female Rainbow Pitta collected by a scientist was subsequently found to have two eggs in her oviduct. This is a remarkable event, and one which must be extremely rare among birds. Clearly, it involves the not insignificant risk that the eggs, squashed together into a small space, will break, which would have fatal consequences for the female.

Pitta eggs are broadly ovoid, with one end slightly pointed. The surface is generally smooth, the only exception being the deeply pitted eggs of the Superb Pitta. The eggs are often faintly glossy, although this varies within and between clutches. The ground colour is creamy white to whitish, this being marked with spots, dots, hieroglyphic-like markings, scrolls and streaks of dark brown, red-brown, pale brown and black and with diagnostic greyish-lilac to greyish underlying markings. Eggs vary in size according to the size of the species. Those of the little Garnet Pitta are  $28 \times 20$  mm, whereas the two largest species, the Ivory-breasted and Giant Pittas, lay eggs which measure, respectively,  $33 \times 27$  mm and  $32 \times 26$  mm.

Interestingly, the eggs of the Noisy Pitta in Australia are smaller in the north of the range than in the south, averaging  $30 \times 24$  mm in size in Queensland and  $33 \times 25$  mm in New South Wales. In addition, populations north of the Connors Range, in Queensland, most commonly lay three eggs, while those to the south of there normally lay clutches of four eggs. This regional difference in clutch size may be associated with the scarcity of food resources in humid tropical rainforest and the shorter feeding hours available there.

Shared incubation is the rule among the Pittidae. The incubation period is typically 14-16 days, but a period of 15-18 days is recorded for Noisy Pittas. Hatching is usually asynchronous, over a couple of days, but both the Hooded Pitta and Gurney's Pitta have been reported as hatching a whole clutch in a single day. At one closely watched nest of the very rare Gurney's Pitta, the observer noted that all four eggs hatched within a period of less than eight hours; the adults then swallowed the eggshells in their entirety, thereby assimilating the calcium which they contain. It is not known whether the eating of the shells of hatched eggs

Typically, both sexes of a pitta pair collect material and help to build the nest, which takes 2-8 days for completion. Sticks gathered by this lovely blue-backed male **Giant Pitta** will be used to build a platform base for the nest and combined with dead leaves to construct the outer covering. Pitta nests are rather simple structures, loosely held together and lined with plant fibres and fine roots.

Nests are often well concealed through having a roof of moss, larger leaves and other material from the immediate vicinity. A platform of twigs by the entrance hole has been reported for several pitta species.

[*Pitta caerulea*.  
Photo: I. R. Beames/  
Ardea]

The characteristic globular nest of pittas, with a side entrance, is often hidden among vines, roots or fallen branches, by a dead stump, or higher up in a cleft or fork. That of the **Banded Pitta** is usually placed 2-3 m above the ground. The entrance may be, as here, at an angle, so there is no obvious roof, though some also collapse while still occupied. Pittas lay 3-5 (occasionally 2-6) creamy white eggs with a variety of dark markings. The eggs are incubated by both sexes for 14-16 days, the young hatching asynchronously over a couple of days. The adult sits tightly on its nest, seldom leaving at the approach of a human until almost trodden on!

occurs among other members of the family, but the behaviour is certainly a well-known phenomenon in the avian world in general. The eggs of a Giant Pitta which was kept in captivity hatched 12 hours after the first signs of pipping.

The nestlings are born naked and blind, and are entirely dependent on their parents for food, warmth and general care. Newly hatched Banded Pitta chicks are reported to have a grey down, which is lost after only three days. Biparental care continues after hatching, but rather little detailed information is available for this stage of the breeding cycle. In the case of Gurney's Pitta, the female broods the chicks at night and the male assists with duties during the daytime. After three days, brooding by day becomes less continuous, and the adults appear to cease brooding alto-

gether once the young reach eight or nine days of age. On the other hand, a female Giant Pitta continued to sit with her offspring at night until two days before they fledged, perhaps because of frequent visits by snakes. A captive female Banded Pitta spent most of her time in the nest during the nestlings' first five days. During the early stages of the chicks' development their droppings are enclosed in a gelatinous faecal sac, which the parents, after having fed the brood, remove and carry some distance away from the nest.

At a nest of Hooded Pittas studied in New Guinea, provisioning visits were made, on average, every 14.6 minutes by the male parent and every 18 minutes by the female. During the brood-feeding stage, one pair of Gurney's Pittas made some 2399 visits to the nest, travelling an estimated total distance of 460 km over a period of 15 days. Observations of Gurney's and Giant Pittas have revealed that even moderate rainfall does not disrupt the parents' regular feeding rhythm.

As breeding often coincides with the beginning of the wet season, earthworms are the most frequent food items brought to the nestlings. For example, worms were delivered in 46 of 63 feeding visits by a pair of Gurney's Pitta. In a recent study investigating the importance of feeding ecology to the breeding success of Eurasian Blackbirds, D. E. Chamberlain and others demonstrated that both provisioning rates and nestling weights were marginally higher when the chicks were fed on a diet consisting predominantly of earthworms. This affords support for the presumption that worms also have a high nutritive value for pittas. When the chicks are small, the parents chop the earthworms into small pieces before feeding them to the brood.

Although earthworms can appear to form up to almost 80% of the nestlings' diet, this could be merely a reflection of the fact that such worms are more easily identifiable than are most other food items, especially small ones. Adult pittas do, in fact, feed their young with a variety of foods, including various insects, grubs, snails, centipedes and spiders. Leeches are among the items reported to have been fed to young Noisy Pittas, and small frogs were brought to chicks of Gurney's Pitta.

The young develop and grow rapidly, with fledging occurring at an age of 15-17 days. Earlier fledging has been reported, but this is probably the result of the young leaving the nest in order to avoid predators or intrusive observers. Such youngsters,

The breeding biology of the **Bar-bellied Pitta** has not been well studied, but both sexes are known to build the nest, and both also share in incubation, as can be seen here with the female about to take over from her mate. No changeover ceremony has been described for this species. During observations of a pair of Noisy Pittas (*Pitta versicolor*), the incoming bird, usually bringing soft material to add to the nest, would call from some distance, causing its mate to leave.

often only two-thirds the size of an adult, can fly short distances, but they are not able to gain height and must, therefore, rely on their well-developed legs if they need to escape from potential predators. Very little is known about the period of post-fledging dependency, but it seems likely in most cases, at least, to be no more than about ten days and, in some cases perhaps, shorter. The fledglings of the Banded Pitta, for example, are independent at an age of 22-24 days, but a brood of young in captivity began to take food for themselves when only 19 days old, just four days after leaving the nest.

Nest failure is frequently reported. Of a total of 14 eggs in four Gurney's Pitta nests, two were infertile and four were preyed upon; from the eight eggs which hatched, three chicks were taken by predators and only five survived to the fledging stage. Unfortunately, it was not possible to monitor the fortunes of the five fledglings during the first vulnerable weeks of independence. Although there are no complete breeding-success statistics for any members of the Pittidae, the small clutch size of most species suggests that, as with most tropical birds, nesting success is low, in this case due to heavy predation. The most serious predators during the breeding season are snakes, which probably take a heavy toll of, especially, eggs and nestlings. For example, the Superb Pitta on the island of Manus suffers heavy predation by the ground boa (*Candoica aspera*) and the brown tree snake (*Boiga irregularis*). Birds which are confined to small islands are frequently subject to serious predation by introduced animals. The rarity of the Black-faced Pitta, another threatened species with a limited range, which consists of Bougainville and two islands in the adjacent Solomons, is said to be due largely to the presence of introduced mammals such as cats (but see Status and Conservation).

It is well established that birds living in rainforest lay fewer eggs in each clutch than do their relatives which inhabit cooler regions, although this is compensated for by greater longevity. The oldest pitta recorded in the wild was a Blue-winged Pitta, which was recaptured 67 months after it had first been trapped. Two Hooded Pittas were recaptured 30 and 38 months, respectively, after they had been ringed. Otherwise, a pair of Giant Pittas which was kept in captivity in San Antonio Zoo lived for more than 12 years.

## Movements

Most pittas are sedentary, even at high altitudes, although some post-breeding dispersal does take place. Because many species are normally silent outside the breeding season, some, such as

Gurney's Pitta, were formerly thought to be migrants. As they were not heard during the period when they were not breeding, it was assumed that they had left the area.

Only four species are true migrants. These are the African Pitta, the Indian Pitta, the Fairy Pitta and the Blue-winged Pitta. Most of the populations of these four undertake regular annual migrations in which they cover moderate to long distances. In South-east Asia, the northern populations of the subspecies *cucullata* of the Hooded Pitta is also a true migrant, while populations of the Blue Pitta in north-east India and Bangladesh appear to make local seasonal movements. In Australia, some Noisy Pittas from north Queensland, after nesting, move northwards to spend the non-breeding season on islands in the Torres Strait and in southern New Guinea. The only other pitta which is known to undertake migratory movements on a noteworthy scale and with some regularity is the Red-bellied Pitta in the Philippines, New Guinea and Australia's Cape York Peninsula; these movements, however, are little understood and are perhaps best described as nomadic.

In addition, the subspecies *elegans* and *vigorsii* of the Elegant Pitta probably make some inter-island movements, a supposition based on their apparent absence from the known breeding islands for some months and their pointed wingtips. Any such migrations, however, remain undocumented.

Understanding of pitta migrations is generally poor. As with most other tropical passerines, frustratingly few recoveries of ringed birds exist. For example, of 2000 Red-bellied Pittas caught and ringed at Dalton Pass, in Luzon, the northernmost island of the Philippines, only ten produced recoveries: nine individuals were retrapped at the same site up to two months later, and one was captured 36 months later, when it had moved 48 km to the south-east.

Migration appears to be always nocturnal, making direct study of the movements of these birds still more difficult. Nevertheless, the migrant pitta species are, with the exception of the Fairy Pitta, very abundant, and many reports of large "falls" of Hooded Pittas, Blue-winged Pittas and African Pittas exist. From these documented accounts, it seems likely that pittas migrate in loose flocks and use the same resting and foraging places year after year, with little variation in the annual timing of movements.

There are a few long-distance migrants in the family. In the Afrotropics, the subspecies *longipennis* of the African Pitta travels as much as 2000 km between breeding and non-breeding areas, and there are numerous reports of this species fluttering at or striking window panes at night. The Indian Pitta migrates from the sub-Himalayas to southern India and Sri Lanka, while the northern

Pitta nestlings hatch naked, blind and helpless, but they rapidly acquire a sparse covering of down. These **Blue Pitta** nestlings show their striking yellow and orange gapes as they beg for food from the male parent. The young are cared for and fed by both sexes. Nestlings of Gurney's Pitta (*Pitta gurneyi*) are brooded for 8-9 days, by the female at night, but with the male doing some during the day. Young pittas develop rapidly, fledging at 15-17 days, and post-fledging care probably lasts about ten days.

[*Pitta cyanea cyanea*,

The beautifully coloured **Noisy Pitta**, the commonest pitta in Australia, is found in the country's eastern rainforests.

This individual, its bill packed with earthworms, shows conspicuous white wing patches as it flies to its nest, probably concealed among tree roots. Both parents share in the feeding of the young, and one male was recorded feeding his female on the nest after the second egg had hatched; each adult used its own route and lookout perch when approaching the nest; towards the end of the fledging period, the young were especially vocal upon the arrival of a parent. These birds foraged close to the nest-site initially, but further away and independently, when collecting food for their offspring.

[*Pitta versicolor versicolor*, Lamington National Park, Queensland, Australia. Photo: Glen Threlfo/ Auscape]

populations of the Blue-winged Pitta in southern Myanmar and Thailand "leap-frog" more southerly ones and migrate all the way to Sumatra and Borneo. The latter species is prone to vagrancy, with, for example, two records from north-west Australia, one from Christmas Island, south of Java, and two from the Philippines, although those from Australia have been disputed.

One of the least understood long-distance migrants is the Fairy Pitta, the breeding range of which extends from southern Korea and Japan in the north to eastern China and Taiwan in the south. The supposed main wintering range lies in northern Borneo, but the route taken by migrants remains a mystery. There are two main possibilities. Fairy Pittas breeding in the south-western part of the range, in China, may fly through Vietnam and then make the 1000-km sea crossing direct to Borneo. Those from Korea and Japan may cross the East China Sea to Taiwan, a distance of about 1100 km, and from there continue on over the 350 km or so of water to Luzon, and then across the Philippines to Borneo. Evidence that the first route is used, at least on the return migration in spring, derives from a few birds observed in north and central Annam, east Tonkin and Hong Kong, mostly in April. In favour of the latter route are data from the 1980s, when hundreds of these pittas were caught each spring on Taiwan. Fifteen males collected on the island in May ranged in weight from 67.5 g to 155 g, and the fact that some were thus more than twice as heavy as others suggests fat deposition for a transoceanic flight. On the other hand, the Fairy Pitta has never been recorded in the Philippines. To confuse matters even further, the biometrics of individuals collected near Shanghai, on the Chinese east coast, suggested that these birds originated from Korea and Japan, while eight specimens in Borneo appeared to be from southern China. It may be that this species follows two distinct flyways, or perhaps that it makes an autumn migration across the continental mainland and on to Borneo, and takes a more direct return route in spring, when migrating birds are known to make fewer stops and are therefore more difficult to trace. This is an interesting subject for study, and one in which the radio-tracking of even a small number of individuals could provide very useful data.

Most pitta species have no well-defined pattern of migration, but will make local movements, perhaps in response to

food shortage or habitat change, and undertake short-distance post-breeding dispersal. The southern population of the Noisy Pitta performs some east-west and altitudinal movements, and it is likely that similar shifts occur among several other members of the family.

Differential migration has been reported for two species. The 15 Fairy Pittas on Taiwan, mentioned above, were, as stated, all males, and, of eleven Hooded Pittas of the subspecies *cucullata* caught in November-December in the Strait of Malacca, ten were females. Interestingly, separation of the sexes outside the breeding season has been recorded for a non-migratory species, the Banded Pitta, in Java and Borneo.

### *Relationship with Man*

The brilliant colours of the members of the family Pittidae have, in the past, made these beautiful birds highly desired subjects for aviculture. Delacour, in 1934, was the first to breed pittas in captivity, and his success was a great sensation at the time. Pittas are very difficult to breed; they require large aviaries with high humidity and good vegetation, conditions which in normal circumstances, because of the costs involved, only large zoos are able to provide. In addition, pittas are by nature very pugnacious, and it is therefore difficult to find other bird species with which they can live peacefully. This is probably the main reason why pittas are so rarely kept in private collections today.

A well-known colloquial name for the Pittidae is "jewel-thrushes", and this term aptly sums up the spectacularly beautiful appearance of these birds. In much of the family's range, the keeping of birds as pets is a common practice. Naturally, such striking birds as the pittas are very popular, but, since they are primarily insectivores or worm-eaters, they are not easy to keep as pets. Nevertheless, their natural beauty has sometimes made them irresistible. In Borneo, for example, children were once quite happy to retain a pitta, or even just a part of it, once the bird had died; the dead bird would become a favourite toy. Various other colloquial names have been applied to these handsome birds. In Australia, for example, the Noisy Pitta is some-

Virtually all pitta species time their breeding to coincide with the start of the rainy season, the latter encouraging the growth of denser vegetation which, in turn, will better camouflage and protect the nest and young.

The moisture also stimulates the activity of various prey items, notably earthworms, and makes them easier to obtain. For several species, including the **Noisy Pitta**, earthworms are the commonest item fed to the young. In a pair of closely observed Gurney's Pittas (*Pitta gurneyi*), of 63 feeding visits 46 were with worms!

In the early stages of feeding, one pair of Noisy Pittas smashed the worms into small segments on a rock before feeding them to the young; at a later stage, worms were chopped into short pieces.

Its bill crammed with looped worms, this bird recalls a thrush, such as the Eurasian Blackbird (*Turdus merula*), bringing a similar bundle to its nestlings. The typical domed nest seen here, looking like a spherical accumulation of forest debris, is more compactly built than some, appearing to be quite tightly bound together with thin roots.

[*Pitta versicolor*,  
Queensland, Australia.  
Photos: R. Brown/  
Oxford Scientific Films]

The only Australian pitta with black underparts, the brilliant **Rainbow Pitta** has two different and disjunct populations in the north of the country's Northern Territory.

This species inhabits mainly monsoon rainforest, but also mixed forest with the tree *Lophostemon lactifluus* dominant. As seen here, some nests of the Rainbow Pitta are more open, lacking the hood characteristic of other species' nests.

The importance of sticks for the construction and the lining of fine rootlets is obvious. Nests of the Noisy Pitta (*Pitta versicolor*) also have a small twig platform or ramp ("doormat") below the entrance, and the birds sometimes spread this and the inside of the nest with animal dung or mud; similar behaviour has been recorded for the Rainbow Pitta. While one chick is being fed, its siblings continue to gape, and in the end all do so, seemingly insatiable, while the parent lingers. The young will grow rapidly over a nestling period of 14-15 days, being fed by the parents on a diet of worms, snails, insects, and the like. At one nest of the Hooded Pitta (*P. sordida*) in New Guinea, provisioning visits by the male took place every 14-6 minutes, and those by the female every 18 minutes. As an anti-predator strategy, young Hooded Pittas are known to face the inside of the nest, their spiny quills bristling out towards the entrance in defence, while nestlings of other species will crouch and freeze in the nest if threatened.

[Pitta iris iris,  
Darwin,  
Northern Territory,  
Australia.  
Photos: Stanley Breeden/  
DRK]

Both sexes of the widely distributed **Hooded Pitta** share nesting duties, though the female may do most of the incubating and brooding. After a feed, the adults will carry away the faecal sacs of the nestlings and discard them at some distance from the nest. A captive male Banded Pitta (*Pitta guajana*) fed the young alone during the first six days, and collected such faecal sacs from the female. There are also two observations of a male Gurney's Pitta (*P. gurneyi*) swallowing part of a faecal sac. Maintaining nest hygiene in this way is clearly essential if the birds are to avoid parasite infestations.

times referred to as the "painted thrush", "anvil-bird", "bob-tail" and "dragoonbird".

Some species are still caught for the pet and for the cagebird trade. Every year, throughout India, thousands of Indian Pittas are captured while on migration. By placing snares in openings of bushes through which the birds fly, a single experienced hunter is said to be able to catch up to 50 birds within a few hours, using only five to eight nooses. At Dalton Pass, an important flyway in the mountains of Luzon, in the Philippines, migrating Red-bellied Pittas are trapped annually at night by local people using lights, mist-nets and decoys; the exact numbers of pittas involved are not known, but in 1989 and 1990 67 bird-catchers, when asked how many birds they took in a single season, gave an estimated figure of 336,000 individuals of 97 different species. As in India, most were used as food, and some were sold alive to pet shops and markets.

Since pittas, because of their elusive behaviour, are not easy to collect, scientific expeditions have often procured them from local people, who use snares or take the sitting birds on the nest. In the presence of humans, all members of the family are as a rule shy and skulking, but it is nevertheless possible to observe a pitta from only a few metres if the observer remains quiet and still.

A good number of pitta species have been named after the discoverer or in honour of a person. This is reflected in the scientific specific names of as many as nine of the 30 members of the family. The Eared Pitta, whose scientific name is *phayrei*, was named after Lieutenant General Sir Arthur Purves Phayre, who was Commander of the British forces in Burma, now known as Myanmar, between 1862 and 1867. Eugene Oates, a civil servant in India who wrote two volumes of the famous *Fauna of British India* in 1889, had the Rusty-naped Pitta named after him. Schneider's Pitta immortalizes the Swiss taxidermist Gustav Schneider, who collected the first specimens of this species in Sumatra, in the late 1890s; the taxon was subsequently described by E. Hartert, in 1909. Elliot, who wrote the first monograph of the Pittidae, in 1863, was honoured eleven years later when a new species of pitta was named after him, subsequent to which he produced a revised and enlarged second edition of his book. J. H. Gurney, a nineteenth-century English ornithologist, collector and banker, is remembered through the attractive but greatly

threatened species which bears his name, while J. C. Baud, an official of the Dutch East India Company whose life spanned the eighteenth and nineteenth centuries, had the Blue-headed Pitta named after him. The German ornithologist A. Reichenow, who wrote *Die Vögel Afrikas* in the first five years of the 1900s, has given his name to numerous species and subspecies, one of these being the Green-breasted Pitta. The Azure-breasted Pitta commemorates J. B. Steere, who collected the first specimens of this pitta on his two expeditions to the Philippines in the second half of the nineteenth century. The last of the nine eponymous pittas is the Whiskered Pitta, named after Gottlieb von Koch, who was director and taxidermist of the Natural History Museum in Darmstadt, Germany, during the latter part of the nineteenth and the early twentieth centuries.

## Status and Conservation

Rainforest, which formerly occurred in extensive tracts in tropical regions, has been relegated by human activity to a point where it now covers only 7% of the earth's surface, yet it still contains more than half of all plant and animal species known to man. Logging and forest-burning are common in most areas where pittas occur, but few data are available on the effects which these activities have upon pitta communities.

One example is Schneider's Pitta, first discovered in Sumatra between 1897 and 1899, as mentioned above. Up to 1924 it was seen, and specimens were collected, by several expeditions at altitudes of between 900 m and 2200 m, the majority below 1400 m. The species was reported to be common. After one was shot in 1936, however, nobody succeeded in seeing a Schneider's Pitta during the following 52 years, and most authors considered this pitta to be possibly extinct. Then, in 1988, P. Hurrell located a male, and on the following morning a pair, near the summit of Mount Kerinci, at an altitude of 2375 m. A few individuals have since been reported, all at high elevations. It seems likely that illegal slash-and-burn agriculture has destroyed much of this species' habitat at lower altitude, forcing it to retreat to higher levels. Schneider's Pitta has now been found in the Kerinci-Seblat National Park, a large area covering 15,000 km<sup>2</sup>, as well as in the Bukit Dingin/Gunung Dempo

Although no pitta species has become extinct in historical times, nine are currently listed as globally threatened. Probably the world's most threatened habitat and that with the greatest biodiversity, is lowland rainforest, which continues to vanish at an extremely alarming rate. Rainforest is the haunt of many pitta species, and there is no doubt that habitat loss resulting from a huge human population increase and associated changes to the environment has been the main cause of catastrophic declines in many pitta populations. Also of great concern is the lack of basic biological knowledge for a number of species, which could mean that they might be wiped out before they have even been studied. This includes the need for more taxonomic investigations, which may well lead to the recognition as full species of taxa currently held to be "only" subspecies, and this in turn probably means a better chance of encouraging conservation interest and activity in the taxa in question. The general threats of pesticides and introduced mammalian predators have yet to be positively identified as serious problems for pittas, while their trapping for food is likely to be of greater significance than that for the trade in live birds. The best solution to counteract declines seems to be the establishment of more national parks and reserves, as long as these are correctly located and managed, the involvement of local people being crucial to that end. The exquisite **Garnet Pitta** inhabits tall lowland rainforest, including the older stages of regeneration. It thus tolerates some habitat interference and is still locally common in some parts, but the alarming plight facing most of the forest within its range justifies its current listing as Near-threatened.

[*Pitta granatina granatina*,  
Lanjak-Entimau  
Wildlife Sanctuary,  
Sarawak, Borneo.  
Photo: Doug Wechsler/  
VIREO]

Classified as Vulnerable, the **Blue-headed Pitta** is restricted to Borneo, where it favours dense cover in primary and regenerating, selectively logged, lowland evergreen forest, particularly near rivers. Such forest is still relatively extensive in Borneo, but large areas of the species's habitat have disappeared owing to commercial logging, uncontrolled fires and drought, and it is likely that this pitta is suffering a rapid and continuing decline. It occurs in several protected areas, but these need to be effectively and properly controlled if all their wildlife riches are to be preserved and the Blue-headed Pitta is not to slump to the category of Endangered.

[*Pitta baidii*,

VIREO]

Protection Forest, and it has been heard at Berestagi. It is likely that habitat at such altitudes is suboptimal for the species, and there is little doubt that it remains a very rare species, surviving only because of its apparent ability to adapt sufficiently well to conditions at higher altitudes.

Another species on the brink of extinction is Gurney's Pitta. Unlike Schneider's Pitta, this species seems dependent on lowland rainforest below 160 m in elevation, which limits its range in south Thailand to one of the last significant fragments of lowland forest, at Khao Nor Chuchi, in the province of Krabi. As in the case of Schneider's Pitta in Sumatra, the explosion of the human population is the most serious threat for the future of this attractive species. In Thailand, the human population increased by nearly 300% between 1945 and 1980, which has naturally raised the need for more agricultural areas. Gurney's Pitta was rediscovered in 1986, following a hint from a bird-dealer, after it had not been seen in the wild for 34 years and had only rarely been found in the cagebird markets. It was two ornithologists, P. D. Round and U. Treesucon, who located the first breeding pair. They have since studied the species intensively and, after having acquired the basic knowledge of its biology, began to stress the urgent need for conservation of the pitta's habitat.

Because several thousand human families live in and around the range of Gurney's Pitta and obtain their livelihood from the forest, it was necessary to think in new ways. A non-hunting area was already established a year after the species' rediscovery, and its status was upgraded to that of a wildlife sanctuary in 1993. Unfortunately, most of the known pairs of Gurney's Pittas were breeding outside the protected area, where the majority of the rural human population lived, and the government therefore made it a National Reserve Forest. With the support of many conservation organizations, the Khao Nor Chuchi Lowland Forest Project, co-ordinated by the Centre for Wildlife Research in Mahidol University, was started. The first target was to obtain support from local people through offering them direct participation and an interest in the future protection of the forest. This was effected by providing financial incentives for conservation, and by demonstrating to the human inhabitants ways in which they could exploit the forest in a more sympathetic manner while at the same time trying to increase their sparse income.

A Gurney's Pitta School Fund was set up, which provided educational materials for the schoolchildren, and arranged courses and conservation camps. In addition, a silvicultural programme was carried out, involving the reforestation of previously cleared areas with native trees. By 1990, more than 60,000 trees and palms had been propagated and planted, some in rubber plantations, where a rich undergrowth is not an economic problem but does benefit Gurney's Pittas, which have now been recorded breeding there several times, especially in the spiny palms. To facilitate dispersal of the pittas, trees were also planted in such places as along watercourses, thereby creating "corridors" between scattered forest patches. Fish ponds were built, and the artificial breeding of chickens, ducks, pigs and frogs was established, in order to remove the people's need to hunt animals in the forest. Further, the growing of vegetables and fruit was initiated. To finance all this costly work, a bank was opened where the farmers could borrow money on favourable terms.

Moreover, as a means of protecting the area from the activities of poachers, personnel from the Royal Forest Department were provided with vehicles, special headquarters, guard posts and an information centre. The increasing international interest in Gurney's Pitta and in the project itself finally resulted in the building of accommodation for tourists in the village of Ban Bang Tieo, which is situated in the centre of the pitta's range, and even a village meeting hall was established. Additional revenue was made available through various local handicrafts, using local materials, which were organized so as to offer souvenirs for the tourists.

One of the latest efforts has been the production of a detailed and comprehensive land-use and forest-cover map for the area. All homesteads and clearings are mapped, with the owners' names, so that new, illegal, clearings can be detected, and the protected forest has been demarcated with signs at 100-m intervals. Since 1998, the local radio station has broadcast twice-monthly features on the project, and a one-hour film shot in Khao Nor Chuchi has been shown in both the Thai and the English languages on the national Thai Television.

The entire project has been financed by a grant of US\$1,500,000 made on behalf of DANCED by the Danish Ornithological Society and BirdLife Denmark.

Despite the fact that a part of the forest was designated as a wildlife sanctuary, and the rest protected at a lower level, new clearings have nevertheless continued to be established every year. The response from the Thai government has been rather disappointing, and this is especially the case with the Royal Forest Department, which has a responsibility to protect forest inside wildlife sanctuaries. Many officials, however, appear to be engaged more in building their own power base, and from a political point of view there are, sadly, very few votes to be gained in protecting a little bird. To add to these difficulties, there has been a growing shift in agricultural practice from rubber plantations to the more profitable oil palm (*Elaeis guineensis*), in which all undergrowth is bulldozed or blasted from the soil surface. Moreover, the ecotourism programme has not been a success. Income for villagers owning accommodation for the tourists has been very meagre, because most visitors have preferred to sleep elsewhere.

Since over a decade has passed since the project was first set up, it has to be asked how much this huge expenditure of manpower and money has influenced the survival of Gurney's Pitta. Following estimates of about 45 pairs in 1986 and 40 pairs in 1988, a survey in May 2000 resulted in ten pairs being located and two nests being found. There is little argument that the primary cause of this decline continues to be loss of habitat. Furthermore, disturbance by visiting birdwatchers eager to have the species on their lists, and who fail to observe the basic guidelines for proper behaviour within the forest environment, has become a potentially serious problem in more recent years.

Perhaps rather surprisingly, no programme of captive-breeding of the species has yet been planned or organized. All efforts have, maybe understandably, been concentrated on saving the habitat, since this pitta is now confined to a single area of lowland rainforest no more than about 50 km<sup>2</sup> in extent. The breeding of pittas in captivity has generally been found to be a rather difficult task, but in a recent paper published in *Avicultural Magazine* D. Rinke, the director of Vogelpark Walsrode, in Germany, and his colleague B. Marcordes record the successful breeding of one of Gurney's Pitta's closest relatives, the Banded Pitta. In this case, at least, it seems that the problems can be overcome by hand-rearing the young pittas, and the offspring can therefore be fostered in relatively large numbers. Although imprinting on humans has been found to be a significant risk with many other

species bred in captivity, their tameness making subsequent release into the wild problematic, hand-reared pittas appear to show hardly any signs of such imprinting.

There may be a small chance that some individuals still inhabit lowland moist forest and secondary growth in the southern part of Tenasserim, in south Myanmar, from where bird-catchers are said from time to time still to sell live Gurney's Pittas at the border with Thailand. BirdLife International has applied to the military government in Myanmar for a permit to undertake an expedition into the area, but such requests have not been successful. It is believed, however, that forest in Tenasserim is also being cleared at a rapid rate. A few confiscated Gurney's Pittas are kept in various Thai zoos.

Notwithstanding the high level of conservation effort involving the local people, including, for example, the adoption of sustainable agriculture in the Khao Nor Chuchi project area, the clearance of forest still persists, and some hunting and trapping still take place in the sanctuary. A survey in 2001 confirmed that protection and law enforcement at Khao Nor Chuchi are effectively non-existent. The most recent conservation initiatives include special training for the Thai Royal Forestry Department rangers to enable them to achieve more effective patrolling at Khao Nor Chuchi, and a proposal to utilize a plot of about 16 ha in extent for a pilot attempt at replanting, with local villagers being paid to do the work and to protect the plot. A programme of environmental awareness has been established, this being aimed at schoolchildren in the immediate area of the Khao Nor Chuchi site.

The conservation strategy aimed at protecting Gurney's Pitta has reached a bottleneck. The issue now is whether this pitta will be the first bird species to become extinct in the new millennium. Even though the species' current situation may seem desperate, there may nevertheless be a glimmer of hope that it can survive, as it appears to prefer some stages of advanced, well-watered secondary regrowth. One can only hope that the massive resources in terms of finance and manpower which have been devoted to efforts to save this beautiful bird will not have been in vain.

No pitta species has become extinct within historical times. Nine species, however, are currently listed by BirdLife International as globally threatened. The conservation status of Gurney's Pitta, discussed above, is listed as Critical, while that of eight others is listed as Vulnerable. One of these is Schneider's Pitta, also discussed above. The other seven are the Blue-headed Pitta, the Graceful Pitta, the Superb Pitta, the Fairy Pitta, the Azure-breasted Pitta, the Whiskered Pitta and the Black-faced Pitta. The Convention on International Trade in Endangered Species of Wild Flora and Fauna, CITES, includes Gurney's and the Whiskered Pittas in Appendix I and the Fairy Pitta in Appendix II. At the tenth conference of the parties, in 1997 at Harare, in Zimbabwe,

The **Graceful Pitta** is a Sumatran endemic, occurring in the highlands and probably less widespread than the other Sumatran endemic, Schneider's Pitta (*Pitta schneideri*). It is difficult to observe and thus not well known, but must probably be considered rare or very local. Rapid growth of Sumatra's human population, in large part due to the government-backed transmigrations, and replacement of the forest by agriculture are the most serious threats to this pitta's long-term survival, but far more information is needed to form the basis of the necessary conservation strategy. Though Graceful Pittas are known to be present in some protected areas, this is far from a guarantee of security.

[*Pitta venusta*.

The **Rajah Sikatuna National Park**, on Bohol, appears to be a stronghold for the **Azure-breasted Pitta**, endemic to the Philippines, but this park is still under pressure from illegal incursions. There are also recent records from two locations on Mindanao, but no birds have been seen on Samar and Leyte since the 1960s. The small, fragmented population is now probably in rapid decline and is threatened primarily because its rainforest habitat is still being destroyed or heavily degraded.

[*Pitta steerii coelestis*,  
Rajah Sikatuna National Park, Bohol, Philippines.  
Photo: Pete Morris]

The aptly named **Superb Pitta** is richly adorned in glossy black, sky-blue and scarlet. Its entire population, estimated, perhaps rather optimistically, at 1000 calling birds, is confined to Manus Island, and its conservation status is Vulnerable. There is certainly a large area of forest unexplored and a more accurate population estimate is clearly essential in order to develop a conservation strategy. The species is shy and apparently not highly vocal, and it remains poorly known. Further study is needed to clarify habitat preferences, which may involve bamboo thickets or open hilltop forest near a river with stones for breaking snail shells; it may also be able to exist in selectively logged forests and agricultural-forest mosaics. Snakes may represent a serious threat to the Superb Pitta.

[*Pitta superba*, Manus, Admiralty Islands, off northern New Guinea. Photo: William S. Peckover]

it was decided to establish an additional category, Appendix IV (D), in which the Blue-naped, Rusty-naped, African, Azure-breasted, Hooded, Indian and Blue-winged Pittas were placed, while the Banded Pitta has been moved from Appendix II to Appendix IV.

Restricted to lowland forest of Borneo, the Blue-headed Pitta has almost certainly suffered a very rapid decline in numbers as large areas of its habitat have been removed by commercial logging operations. Uncontrolled fires simply add to the problems which it faces. Although the pitta is present in several protected areas, including two national parks, logging in those areas continues on a large scale. It seems likely that, unless the rate of removal of lowland forest is reduced, or, better, halted, and unless protected areas are properly and effectively managed for the benefit of their wildlife, this pitta will soon reach the stage at which its conservation status may have to be raised to Endangered.

The Graceful Pitta, restricted to a few localities in Sumatra, has suffered similar large-scale loss of habitat. A poorly known species which is difficult to observe, it appears to be rare and very local. As with the Blue-headed Pitta, it is present in at least two national parks, but protection of such areas is at best scant. Indeed, the Kerinci-Seblat National Park, one of the places where this pitta occurs, has been stated to be one of the most threatened protected areas within the entire Oriental Region.

Farther east, in the Admiralty Islands, the Superb Pitta is found on Manus, which represents its entire global range. It lives in lowland forest and fragmented forest, but also occurs in secondary growth. This species is very poorly known, and there are very few recent observations of it. Although it has been suggested that it may have a particular liking for bamboo thickets, its habitat preferences remain to be clarified. As elsewhere, fairly extensive logging has already taken place on Manus, but a more serious threat is possibly the presence on the island of two species of snake, the ground boa and the brown tree snake; the latter has

been introduced into Guam, where it has almost eliminated many forest birds. Nevertheless, only a very small part of Manus has been explored so far, and there is still over 1500 km<sup>2</sup> of forest remaining, which may house a larger pitta population than supposed. The species seems not to be very vocal, and could perhaps, therefore, be easily overlooked.

If the Superb Pitta may be more common than has been believed, the same cannot be said about the Fairy Pitta. Despite its large breeding range, which extends from Korea and Japan south to south-east China and Taiwan, the latter species has undergone a rapid decline during recent decades. Until the beginning of the 1980s it was caught by the hundreds every year on Taiwan, but it has now been declared to be uncommon there. In fact, its total world population is now thought to number only a few thousand individuals. Although it has been described by one author as being common in its non-breeding range in the north of Borneo, this may have been the result of confusion with the very similar and far commoner Blue-winged Pitta. Owing to the fact that the Fairy Pitta's population has diminished so rapidly and so markedly, this lovely species is now legally protected in all countries in which it breeds. The vast forest-clearance programme in China, aimed at generating more farmland in this densely populated country, may have played a great part in the pitta's decline, and the trapping of hundreds of individuals annually for the cagebird trade on Taiwan may also have taken its toll, but it is difficult to believe that these are the only explanations. The small size of the population makes it particularly vulnerable to catastrophic events. As the Fairy Pitta is the only true ocean-crossing migrant within the family, the possibility that great numbers have been caught in typhoons and drowned cannot be excluded. Whatever were the main causes of the species' massive reduction, it would seem essential effective protection be afforded to those forests in which it is known still to breed. Furthermore, the problem of hunting in China, where most animals are considered to be exploitable, pittas being no exception, needs to be addressed.

The **Whiskered Pitta** is classified as **Vulnerable**. It is confined to the island of Luzon, in the Philippines, where it is found mainly in montane forests. It is still locally common, but habitat loss is undoubtedly a serious threat in the longer term, even though the species is apparently able to survive in selectively logged forests. The Sierra Madre mountains are a very important stronghold for this pitta, known locally as the "Kong Kong", and this same range supports 27 other threatened bird species, including the Great Philippine Eagle (*Pithecophaga jefferyi*), but even here the Whiskered Pitta is threatened by illegal logging and the islanders' tradition of hunting with snares.

[*Pitta kochi*,  
Luzon, Philippines.  
Photo: Bill Simpson]

Two of the Vulnerable species are confined to the Philippines. The Azure-breasted Pitta occurs on the islands of Samar, Leyte, Bohol and Mindanao. It occurs in only one protected area, the Rajah Sikatuna National Park on Bohol, where it appears to be still locally common. Otherwise, there are recent records of the species from only two other localities, in east and west Mindanao. It has not been recorded from Samar or Leyte since the 1960s. The other species, the larger Whiskered Pitta, lives only in mountainous habitats on Luzon, where it is present in four protected areas. It has been found at a reasonable number of localities since 1990, and subsequent surveys on Luzon indicate that it is com-

mon locally. Both of these pittas, however, are believed to have declined rapidly as a result of the severe loss and degradation of forest habitat that has occurred in the Philippines. Lowland deforestation has been extensive, and in some areas total, and even at the somewhat higher elevations occupied by the Whiskered Pitta logging has destroyed much of the forest. Protected status does not guarantee that an area is safe from exploitation, either. The Whiskered Pitta is additionally threatened by the activities of local hunters, who use snares to catch the birds.

The last of the Vulnerable species is the Black-faced Pitta, which is found on Bougainville and on two of the Solomon Islands, in three subspecies. It is believed to have been rare throughout much of the last century. Recent research on Choiseul yielded no positive result, and the local people were unaware of the pitta's existence. There are no recent records from Bougainville, either, and it may be extinct on both islands. The nominate subspecies had not been seen on Santa Isabel since 1936, but in 1994 the happy news came that it was common in the south-east of the island, at Tirotonga. The pittas there were found in primary forest and small forest remnants, but also in secondary growth in an area with gardens, where they appeared, in fact, to be more common than they were in the larger unbroken forest tracts. The species continued existence elsewhere on Santa Isabel, however, has not been established. It is difficult to determine what may have caused the decline and possible extinction of this beautiful pitta species on the other two islands. Habitat loss could have been a significant factor; in the early decades of the twentieth century, the Black-faced Pitta was known to occur in parts of its range in forested mountain valleys and coastal and alluvial plains, and these areas have been logged since then. It has also been suggested that this ground-nesting species would be susceptible to the many introduced cats and other mammals on the islands. Although this possibility cannot be excluded, the pittas at Tirotonga were found to be living beside settlements where cats, dogs, and rats (*Rattus*) were common. Without further studies, of course, it is impossible to be certain of what adverse effects, if any, these mammals may have been having on the breeding success of the Black-faced Pittas.

Three species are considered Near-threatened. These are the Giant and Garnet Pittas of southern South-east Asia, Sumatra and Borneo, and the Mangrove Pitta, which occurs at scattered localities from Bangladesh south to Sumatra. The first two are

The Vulnerable **Black-faced Pitta**, apparently always rare, is an endemic of Bougainville, Choiseul and Santa Isabel in the Solomon Islands group. Sadly, it may be extinct on the first two of these, but in 1994 it was discovered to be common at Tirotonga on Santa Isabel. Found there in both primary forest and a patchwork of forest, secondary thickets and gardens, it is actually commonest in the garden thickets. Introduced mammals appear not to constitute a major threat, and a planned ecotourism facility at Tirotonga should help to boost conservation of Santa Isabel's rare and outstandingly beautiful pitta.

Formerly relatively numerous, the Critically Endangered **Gurney's Pitta** was rediscovered in Thailand in 1986, some 34 years after it had apparently disappeared. In-depth studies soon led to its becoming better known than any other pitta species. The prime focus has been on habitat conservation, comprising a host of initiatives involving local people. Sadly, despite all the huge expense and effort, lowland rainforest is still being destroyed, and a single small area of forest now holds just ten pairs. However, the bird does seem to prefer some stages of secondary growth and there is a slight hope that it may survive in Myanmar.

forest species, the Giant Pitta inhabiting lowlands and hills, occasionally up to about 1200 m, and the Garnet Pitta preferring lowland evergreen forest below 600 m. Both have suffered greatly from the massive destruction of forest which has taken place throughout their ranges during the twentieth century. Fortunately, each species seems able to adapt to heavily disturbed habitats and secondary growth, while the Giant Pitta's use of submontane slopes, which have not, so far, been so heavily deforested, has assisted its survival. The Mangrove Pitta, being confined to coastal mangroves, probably has a rather small population size. As with the previous two species, the greatest threat to this pitta is habitat loss; mangroves are heavily exploited for their timber, which is used as a source of fuel and building materials, as well as for the production of charcoal. While all three species are not currently believed to be at risk, the destruction and degradation of their habitats continue inexorably in all parts of their ranges, and could well lead to a change in their conservation status.

A fourth taxon is also considered Near-threatened. The subspecies *dohertyi* of the Red-bellied Pitta is found only on the Banggai and Sula Islands, to the east of Sulawesi, where it inhabits lowland evergreen forest below 200 m. Although this habitat is subject to increased clearance and disturbance, the pitta appears able to survive well in secondary forest and heavily degraded forest, and is perhaps not at any immediate risk. Often treated as a separate species, the "Sula Pitta" (see Systematics), it is local and generally uncommon.

Many of the numerous subspecies of the Red-bellied and Hooded Pittas, the combined ranges of which cover a vast area extending from the Himalayan foothills and the Philippines in the north to the Sunda Islands and New Guinea in the south, have not yet been monitored. Judging from the few old museum skins, some of them are so distinctive that future workers will probably regard them as valid species (see Systematics), provided that they are not exterminated before taxonomic studies can be carried out. Besides the Near-threatened taxon *dohertyi*, mentioned in the preceding paragraph, this applies to the Red-bellied Pitta subspecies *rubrinucha* from Buru, in the Moluccas, *novaehibernicae* from New Ireland, in the Bismarck Archipelago, and *splendida* from Tabar Island, east of New Ireland. The last of those is still reportedly common. Similarly, the taxon *novaeguineae* is widespread in New Guinea, and may be a distinct species, separate from the Hooded Pitta.

The Blue-naped Pitta was once a common bird, but is now considered scarce in most of its range, where extensive forest clearance has taken place. The same applies to both the Blue-rumped and the Rusty-naped Pittas. All three of these closely related species are dull-coloured and skulking and are therefore difficult to monitor. The Blue-naped and Blue-rumped Pittas were formerly listed as Near-threatened, as also was the Bar-bellied Pitta, but it now seems that they survive in sufficiently large numbers to sustain their populations.

Although the majority of the members of this family are to a rather large degree sensitive to human disturbance of the environment in which they live, some appear to be more adaptable. Several species demonstrate a high tolerance of habitat degradation, one example being the Blue-winged Pitta of South-east Asia, which is found in a variety of primary and secondary habitats, as well as in plantations and gardens. In Thailand, for example, where few tracts of lowland forest still persist, even the Near-threatened Giant Pitta has been located in small patches of forest or in scrub, and a pair was found breeding in a 2-ha grove of secondary growth, approximately 2 km from the nearest forest.

Gould, one of the foremost nineteenth-century ornithologists, referred to the subspecies *irena* of the Banded Pitta as "one of Nature's living jewels". It is clear that the greatest threat to pittas, and to many other tropical bird species, is habitat degradation and destruction. Unfortunately, the majority of the Pittidae live in countries with hard-pressed economies, and where the human struggle for daily food is deemed to be more important than the conservation of nature and natural resources. The Gurney's Pitta project at Khao Nor Chuchi sets an example of what may perhaps be the only way for the richer nations of the world to help to save the last living jewels of the rainforest.

# Genus *PITTA* Vieillot, 1816

## 1. Eared Pitta

### *Pitta phayrei*

**French:** Brève ornée **German:** Ohrenpitta **Spanish:** Pita Orejuda  
**Other common names:** Phayre's Pitta

**Taxonomy.** *Anthocincla Phayrei* Blyth, 1862, Tounghoo, Myanmar.

Sometimes placed in a separate, monotypic genus *Anthocincla*, and such treatment may indeed be more appropriate; differs from other pittas by shorter legs, slightly decurved and slender bill, and longer hind claw; shows distinctive horn-like "ears"; performs an acoustic display, apparently unparallelled in the family, with wings producing knocking sounds; foraging technique is more static, involving less constant movement about territory. Allegedly darker birds from NE Tonkin sometimes separated as race *obscura*, but individual variation considerable. Monotypic.

**Distribution.** NE Bangladesh, and C & SE Myanmar and W, NW & E Thailand E to S China (S Yunnan) and S to Indochina (S Cambodia, C Annam).

**Descriptive notes.** 22 cm. Male is plain red-brown above, sides of forecrown yellow-ochre scaled black, central crown and nape black; face dark brown, long black-edged whitish feathers resembling horns on side of crown; wings and tail dark red-brown, outer flight-feathers with pale band, wing-coverts edged yellow-ochre; chin and upper throat white, rest of underparts rufous-buff with variable amount of black spots; iris brown; bill blackish; feet flesh-brown to pale brown. Female is duller, ear-tufts shorter, underparts more spotted. Juvenile is duller than female, with few spots below; tip of bill and base of lower mandible

yellow. **Voice.** A drawn-out whistling "whee-ow-whit", similar to that of *P. cyanea* but more drawn out; also, a short, dog-like yelp or whine as alarm and contact call.

**Habitat.** Lowland rainforest, second growth and mixed deciduous forest and bamboo. Prefers drier areas than those occupied by *P. cyanea*. Commonest below 900 m, but occurs to 1830 m in Myanmar, Thailand and China.

**Food and Feeding.** Snails. Feeds on ground among leaf litter and rotten wood of fallen tree trunks, suggesting that many different invertebrates are also taken. Commonly employs a more static foraging technique than other members of family.

**Breeding.** Recorded in Apr-Aug in Myanmar; juvenile seen in late Oct in Thailand. Nest globular, with side entrance, loosely built of roots, leaves and grass, on ground with small "path" of sticks up to entrance. Clutch 4 eggs, creamy white with dark brown spots and underlying grey-lilac spots, 27 × 21 mm; no further information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Widespread but rare throughout most of range. Reportedly rare also in 19th century, but described as locally common in SW Cambodia in 1938 and at Nam Khueng (NC Laos) in 1940. In Thailand, most easily found nowadays at Khao Yai and Khao Soi Dao National Parks, and also present in Huai Kha Khaeng Wildlife Sanctuary. Common in S Laos (Houay Bangliang) in 1995/96. Uncommon in Myanmar, Tonkin and C Annam. Very rare in China (Yunnan); possible record in 1990 on Hainan, but status there unknown. Seems to be tolerant of some habitat alteration. No hunting or commercial trading of this species has been reported. Although it is not currently considered threatened, this may perhaps be due to the fact that it has been very little studied; survey work is therefore recommended.

**Bibliography.** Bangs & Van Tyne (1931), Bingham (1903), Campey (1996), Cheng Tsohsin (1987), Collar *et al.* (1994), Deignan (1945), Delacour (1927), Delacour & Greenway (1940), Delacour & Jabouille (1931, 1940), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Duckworth *et al.* (1999), Engelbach (1938), Etchécopar & Hüb (1983), Evans & Timmins (1998), Inskipp *et al.* (1996), Kazmierczak (2000), King *et al.* (1975), Lekagul & Round (1991), MacKinnon & Philipps (2000), Riley (1938), Robson (2000c, 2000d), Round (1988, 2002), Smythies (1986), Stattersfield & Capper (2000), Strange (2000), Stuart Baker (1922-1935, 1934), Vestergaard (1998), Wang Sung (1998), Whitehouse (1988), Yang Lan (1983).

## 2. Blue-naped Pitta

### *Pitta nivalensis*

**French:** Brève à nuque bleue **German:** Orangestirnpitta **Spanish:** Pita Nuquiazul  
**Other common names:** Nepal Pitta

**Taxonomy.** *Paludicola Nivalensis* Hodgson, 1837, Nepal.

Has on occasion been placed in a separate genus, *Hydrornis*, along with *P. soror* and *P. oatesi*; these three are closely related. Form *nuchalis*, from Darjeeling, now considered synonymous with nominate *nivalensis*. Two subspecies recognized.

**Subspecies and Distribution.**

*P. n. nivalensis* (Hodgson, 1837) - Himalayas from C Nepal and SE Tibet E to S Arunachal Pradesh and E & S Assam, S to N West Bengal, Bangladesh (Chittagong Hills) and N, W & S Myanmar (Chin Hills, N Arakan Hills and upper Chindwin).

*P. n. hendeei* Bangs & Van Tyne, 1931 - S China (S Yunnan, SW Guangxi) S to N & C Laos and N Vietnam (Tonkin, extreme N Annam).

**Descriptive notes.** 22-25 cm; 110-132 g. Male has uniformly dull olive-green upperparts, tail with faint blue tinge; head rufous to buffish with black postocular stripe, hindcrown, nape and a variable part of upper mantle bright turquoise-blue; wings brown, edged buffish-brown; underparts cinnamon-buff, often with pinkish wash on chin and upper throat, latter with broken black band(s); iris brown; bill brown; feet brownish-flesh. Female differs in having hindcrown and nape green, upperparts more brown. Dusky stripes found on upperparts of 34% of 122 adults examined (both sexes, both races). Juvenile is dark brown, mixed with pale buffish streaks on crown, buffish and

white spots on body except for white belly. Race *hendeei* is smaller, typically with smaller blue patch on nape, although this feature appears to be somewhat variable. **Voice.** Call a sharp and powerful "chow-whit", "uk-wuip" or "ip-wuip"; soft chuckle exchanged by partners when feeding.

**Habitat.** Tropical and subtropical secondary forest, bamboo growth and clearings with dense vegetation, usually near water; on limestone rock in N Annam and in riparian woodland and swamp-forest in India. Occurs in lowlands but more often at higher elevation; mostly to c. 1500 m, but reported to 2150 m.

**Food and Feeding.** Diet includes ants, beetles and other insects, grubs, worms, snails, also lizards, and even field mice reported. Feeds on the forest floor, in swamps and brooks, where large bill is used to overturn dead leaves and dig into soil.

**Breeding.** Laying Apr-Aug, mostly May-Jun; double-brooding reported. Domed nest with side entrance, rather loosely built from bamboo leaves, grass and roots, and placed on ground, or more tidily constructed and placed low down in bush or tree. Clutch 3-5 eggs, creamy white with some red-brown spots and underlying grey-lilac markings, mean size in India 29.5 × 22.4 mm; both sexes incubate and both care for young.

**Movements.** Local migrant in India; otherwise largely sedentary, with some altitudinal and dispersive movements.

**Status and Conservation.** Not globally threatened. Very little information available. Fairly common in Bhutan, but scarce in Nepal and Sikkim. Few recent records in India, though locally quite common in Namdapha National Park, Arunachal Pradesh; rare non-breeding visitor in Kaziranga National Park, in Assam. Scarce to uncommon in Myanmar and Tonkin; locally common at Nam Theun drainage basin in C Laos, but scarce in N Laos. Status of S Chinese population uncertain, probably rare at best. Because of its skulking and secretive behaviour, this species' status is not easy to assess. Judging from the literature and the large number of birds collected in earlier times, it was more common in first half of 20th century. No reports of hunting or of trapping for the cagebird trade. Monitoring of populations considered desirable.

## 3. Blue-rumped Pitta

### *Pitta soror*

**French:** Brève à dos bleu **German:** Blaubürzelpitta **Spanish:** Pita Lomiazul  
**Other common names:** Blue-headed(!)/Blue-backed Pitta

**Taxonomy.** *Pitta (Hydrornis) soror* R. G. W. Ramsay, 1881, Saigon, Vietnam.

Has on occasion been placed in a separate genus, *Hydrornis*, along with *P. nivalensis* and *P. oatesi*; these three are closely related. Populations of SE Laos and C Annam often separated as race *annamensis* on basis of geographically discrete range coupled with more extensive lilac colour on face and crown; owing to great variation in, especially, amount of lilac, however, and insufficient museum material and field studies, considered better treated as synonymous with nominate. Five subspecies recognized.

**Subspecies and Distribution.**

*P. s. tonkinensis* Delacour, 1927 - S China (Guangxi) and N Vietnam (C Tonkin).

*P. s. petersi* Delacour, 1934 - SE Tonkin, N Annam and C Laos.

*P. s. douglasi* Ogilvie-Grant, 1910 - Hainan.

*P. s. soror* R. G. W. Ramsay, 1881 - SE Laos and Vietnam (C & S Annam, Cochinchina).

*P. s. flynnstonei* Rozendaal, 1993 - SE Thailand and SW Cambodia.

**Descriptive notes.** 22-24 cm; 102-120 g. Male has rufous-lilac on forehead and forecrown, becoming bright blue on hindcrown and nape; side of head rufous-lilac, narrow orange-rufous posterior superciliary stripe, black postocular stripe; upperparts bright green, rump bright blue, tail green; wings dusky brown, edged green; underparts orange-rufous, often narrow, broken black upper breastband; iris dark brown to sepia; bill pale pinkish-horn; legs and feet flesh-coloured to orange-cinnamon. Female is duller all over, with less blue on nape. Dusky stripes found on upperparts of 44% of 54 adults examined (both sexes, all races). Juvenile is

dark brown above, crown with buffish streaks and upperparts spotted buffish, plain dirty cinnamon below, paler buffish-pink on throat, often some black spots on upper breast, tip of bill paler. Races differ in size and colour tones: *tonkinensis* is largest, with blue-tinged green crown and nape, tending to paler, pinker colour below, female with only faint blue and green tones on crown and nape; *petersi* is somewhat smaller than previous, very similar to nominate, crown and nape pale blue with faint greenish tinge; *douglasi* is smaller than previous, more purple face and forecrown, green crown, breast washed with pink, female with only faint blue and green tones on crown and nape; *flynnstonei* resembles nominate, but larger. **Voice.** Possibly some geographical variation: a full "weaeo" or "weeya", repeated at 7-second intervals or longer, described from Tonkin; most frequently heard call in Vietnam a frog-like "ppew" or "eau", this and "cho" possibly an alarm note; a single sharp "hwip" or "whit" when disturbed at nest; in Thailand a sharp, breathless "tew" and longer, descending "tiu".

**Habitat.** Wide range of habitat types occupied, from moist riverine primary evergreen forest to secondary or logged forest, mixed forest with bamboo, forest dominated by fan palms (*Licuala*) on

dry steep slopes, or on craggy limestone ground. Rarely in bamboo-dominated forest, and not found in deciduous areas. Lowlands from 50 m to 1700 m in Vietnam, 90-850 m in Laos, and 900-1650 m in Thailand.

**Food and Feeding.** Only snails reported as being consumed; probably insects and earthworms also taken. Uses rocks and stones as “anvils” for smashing snail shells.

**Breeding.** Only three breeding records documented, all in Jun from Vietnam, where also fledglings observed in Jun-Aug. Domed nest constructed of dead leaves, dry rattan leaves, long strips of palm leaves, and black rootlets, with platform of twigs in front of side entrance, placed 1.3-2.4 m above ground in tree or palm c. 4-5 m tall. Clutch 3 eggs, white with pinkish tinge and spotted chocolate-brown, 29 × 22 mm; no other definite information.

**Movements.** No information available; probably sedentary.

**Status and Conservation.** Not globally threatened. Generally fairly common to scarce. In Vietnam, common in Ha Tinh and Quang Binh provinces, Cuc Phuong National Park and Son Tong, and also recorded from Tu Phuc, N Annam; in Laos, common at Xe Piau and observed at Dong Hua Sao, Pha Som/Naliang and Nam Theun; fairly common but local in SE Thailand. Endemic race *douglasi* very rare on Hainan. No abundance data available from other parts of range. General status difficult to judge owing to its reclusive behaviour, but seems to be fairly tolerant of habitat interference. Not known to be hunted by local people for food or regularly caught for cagebird trade. Present in several protected areas, e.g. Nam Bai Cat Tien and Bach Ma National Parks (Vietnam), Xe Pian National Biodiversity Conservation Area (Laos) and Jian Jenling Nature Reserve (China).

**Bibliography.** Bangs & Van Tyne (1931), Campey (1996), Cheng Tsohsin (1987, 2002), Collar *et al.* (1994), Delacour (1927), Delacour & Jabouille (1929, 1940), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Duckworth *et al.* (1999), Dymond (1988), Eames & Ericson (1996), Eames & Robson (1992), Eames, Eve & Tordoff (2001), Eames, Lambert & Cu (1994), Eames, Robson *et al.* (1991), Ellis (2002), Échécopar & Hùe (1983), Evans & Timmins (1998), Hall (1952), Lambert *et al.* (1995), Le Trong Trai (1999), Le Trong Trai & Richardson (1999a), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Robson (1991, 1994, 2000d), Robson, Eames, Nguyen Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Round (1988), Rozendaal (1988, 1993), Stattersfield & Capper (2000), Stepanyan (1993), Thewlis *et al.* (1996), Yang Lan (1983).

4. Rusty-naped Pitta

Pitta oatesi

**French:** Brève à nuque fauve      **German:** Rostbauchpitta      **Spanish:** Pita Rojiza  
**Other common names:** Fulvous Pitta

**Taxonomy.** *Hydroornis Oatesi* Hume, 1873, Toungoo district, Upper Pegu, Myanmar. Has on occasion been placed in a separate genus, *Hydroornis*, along with *P. nipalensis* and *P. soror*; these three are closely related. Racial identity of birds in S Vietnam (S Annam) uncertain; tentatively placed with *bolovenensis*. Four subspecies recognized.

**Subspecies and Distribution.**

- P. o. oatesi* (Hume, 1873) - N, E & SE Myanmar E to NE Laos and S to W, S and NE Thailand.
- P. o. castaneiceps* Delacour & Jabouille, 1930 - S China (S Yunnan), NW Vietnam (W Tonkin, N Annam) and C Laos.
- P. o. bolovenensis* Delacour, 1932 - S Laos and S Annam.
- P. o. deborah* B. F. King, 1978 - C Peninsular Malaysia.

**Descriptive notes.** 23-25 cm; 117-124 g. Male has crown and nape rufous, side of head paler rufous to buffish with a blackish postocular stripe; upperparts and tail dull dark green, often with blue wash, especially on rump; wings dark olive-brown, edged buffish; underparts rufous, chin, upper throat and belly paler, often broken blackish breastband; iris brown; bill pale brown to dark vinous brown; feet flesh-pink to light orange. Female has crown often finely edged black, and upperparts less green, with rufous wash. Dusky stripes found on green upperparts of 55% of 95 adults examined (both sexes, all races). Juvenile is dark brown, crown

and nape with whitish streaks, upperparts and breast with large whitish spots, chin, throat and belly off-white with brown and buffish mottling; iris brown with grey outer ring. Race *castaneiceps* is slightly larger, crown and nape more reddish; *bolovenensis* has top of head more rufous, back more green, rump intense blue; *deborah* resembles last, but slightly smaller and darker. **Voice.** Most common call a sharp “chow-whit” with upward inflection on second note, given every 4-5 seconds and often up to 25 times when breeding; explosive, falling “poouw”, possibly a female call; alarm call “tchick” or “chek”, becoming “chur-r-r-rt” or “wer-r-r-rt” when intruder near nest.

**Habitat.** Prefers dense primary and secondary montane forest, often with ravines and broken ground; often seen near gulleys. Also reported from limestone hills in Tonkin. Ranges from 380 m up to 2600 m; found at higher altitudes than *P. nipalensis* and *P. soror*.

**Food and Feeding.** Insects, grubs, slugs, small snails and worms; also seen foraging among kitchen waste. Forages among leaf litter, turning over dead leaves with the bill.

**Breeding.** Main season Feb-May, but breeding also reported in Sept in Thailand. Domed nest built of dead and skeletonized leaves, twigs, stems of ferns and rootlets, with side entrance, and situated up to 3 m above ground in palm; possibly sometimes on ground and with stick platform leading to entrance. Clutch 2-5 eggs, occasionally 6, creamy white with dark brown and red-brown spots and blotches and lilac-brown underlying markings, mean size in Myanmar 28.5 × 24.3 mm; nestling period at least 19-20 days.

**Movements.** Resident in Peninsular Malaysia and probably also elsewhere in range.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. In Thailand, rare at Doi Pui and uncommon elsewhere; no recent information from Myanmar. In Peninsular Malaysia, c. 5 pairs/km² at Fraser’s Hill; uncommon at Larut Hills (Perak), and from Genting Highlands (Pahang) to Gunung Telapa Buruk (Negeri Sembilan). Very rare in China (S Yunnan). A very shy and secretive pitta, easily overlooked. Not known ever to have been hunted for human consumption or trapped for the cagebird trade, and no other threats at present. Any destruction of the species’ forest habitats could, however, lead to serious declines or local extinction.

**Bibliography.** Anon. (1989b, 1989c), Bangs & Van Tyne (1931), Cheng Tsohsin (1987, 2002), Collar *et al.* (1994), Deignan (1945, 1963), Delacour & Jabouille (1940), Dickinson & Chaiyaphun (1973), Dickinson *et al.* (2000), Duckworth *et al.* (1999), Eames & Ericson (1996), Eames *et al.* (2001), Échécopar & Hùe (1983), Evans & Timmins (1998), Hill *et al.* (2001), Jeyarajasingam & Pearson (1999), King, B.F. PLATE 5

## PLATE 5

## Family PITTIDAE (PITTAS) SPECIES ACCOUNTS

### 5. Schneider's Pitta

*Pitta schneideri*

French: Brève de Schneider

German: Rostkappentitta

Spanish: Pita de Schneider

**Taxonomy.** *Pitta schneideri* Hartert, 1909, Batak Mountains, upper Deli, north-west Sumatra. Closely related to *P. caerulea*, and also to *P. cyanea*; may also share some affinities with *Hydrornis* group. Monotypic.

**Distribution.** Highlands of Sumatra.

**Descriptive notes.** 21-23 cm. Male has top of head and nape bright chestnut-orange, black eyestripe, buffish side of head with many feathers edged black, giving spotted appearance; upperparts and tail shining ultramarine-blue; wings brown; chin and throat white, broken black breastband, rest of underparts orangey-buff; iris red-brown to brown; bill dark brown, tip and base paler; feet light brown with purplish tinge. Female has brown upperparts with blue rump and tail, and is otherwise generally duller than male. A few dusky stripes on blue upperparts of only two of 17 adult males and females examined. Juvenile has dark brown crown and nape spotted pale buffish, warm brown upperparts, dark grey-blue tail, whitish throat, rest of underparts mottled orange-brown mixed with brown; female duller than male. **Voice.** A soft, protracted, double whistle, first note rising, second falling, repeated up to 11 times at intervals of 5-6 seconds; calls just after dawn.

**Habitat.** Mountain primary forest, most often with dense undergrowth and treefall clearings or near forest edge. Most older records are at 900-1400 m, but now found from 1700 m up to 2400 m. **Food and Feeding.** Feeds on large cockroaches (Blattodea) and large snails, and also seen with a prey item which looked like a large grey millipede (Diplopoda); vegetable food also reported. A pair observed foraging by vigorously turning over dead leaves on the forest floor.

**Breeding.** Possibly breeds in Feb-Jun, as juveniles found in Mar-Jul. Nest and eggs not described.

**Movements.** Presumably sedentary, but possibly some altitudinal movement.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Sumatra and Peninsular Malaysia EBA. Has been found so far at fewer than ten localities. In 1914, it was found to be common in Kerinci Valley and on Mt Kerinci, in Kerinci-Seblat National Park, at up to 2200 m

but mostly below 1400 m; following the collection of a specimen in 1936, however, there were no reported sightings for over 50 years and the species was feared extinct. Then, in 1988, a male and a pair were discovered on Mt Kerinci, at 2375 m, with subsequent reports from Mt Tuijuh (1900 m) and Mt Dempo (c. 1750 m) in the Bukit Dingin/Gunung Dempo Protection Forest, and it has been heard at Berestagi in the Batak Highlands. Recent reports from Dolok Sibual Bual Nature Reserve remain unconfirmed. Greatest threats are slash-and-burn agriculture, timber concessions and a growing human population, which have habitat likely to be suboptimal. The species' presence within the Kerinci-Seblat National Park is, sadly, no guarantee for its survival; hunting with air-guns and ground snares is commonly observed in the park. More data are required in order for an accurate assessment of its present conservation status to be made and, moreover, for any comprehensive conservation programme to be formulated. Not known to be kept in captivity. **Bibliography.** Andrew (1992), Anon. (1988b, 1988c, 1989a), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Dickinson *et al.* (2000), Holmes (1996), Holmes & Nash (1991), Hurrell (1989), MacKinnon & Philipps (1993), van Marle & Voous (1988), Robinson & Kloss (1918b), Robson (1989b, 1997b), Rozendaal (1990), Stattersfield & Capper (2000), Sujatnika *et al.* (1995), Tobias (1995), Wells (1985b).

### 6. Giant Pitta

*Pitta caerulea*

French: Brève géante

German: Riesenpitta

Spanish: Pita Gigante

Other common names: Great Blue Pitta

**Taxonomy.** *Myiothera caerulea* Raffles, 1822, Sumatra.

In the past was sometimes placed in a separate genus, *Gigantipitta*, on account of very large size; closely related to *P. schneideri*, and also to *P. cyanea*; may also share some affinities with *Hydrornis* group. Two subspecies recognized.

**Subspecies and Distribution.**

*P. c. caerulea* (Raffles, 1822) - S Myanmar (S Tenasserim), S Thailand, Peninsular Malaysia and Sumatra.

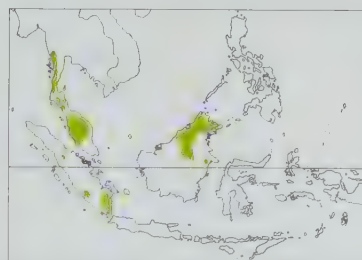

*P. c. hosei* Baker, 1918 - N, SW, C & E Borneo.

**Descriptive notes.** 25-29 cm; male 202 g. Male has head pale to rather dark grey-brown with black scaling, especially on crown; black eyestripe, black stripe from crown to nape, blackish hindcollar; upperparts and tail blue; innerwing and scapulars blue, outerwing dark brown, secondaries edged grey-blue; underparts golden buffish-grey, black collar broken in centre of upper breast; iris hazel to dark brown; strong bill black; feet pinkish-grey. Female is browner, barred on forehead to nape, upperparts and wings plain red-brown. Dusky stripes found on upperparts of 17% of 36 adults examined (both sexes, both races). Juvenile is mottled golden ochre and dark brown, paler below, tail dull blue; bill orange-flesh, tipped yellow. Race *hosei* male is similar to nominate but generally darker on head, though both races are variable; female more rufous on head, with black edgings reduced, and almost lacking on nape. **Voice.** Slow and mournful "hwoo-er" and soft "wheer" often repeated many times, the latter possibly as contact or alarm; "phooooooooou", dying towards end, also reported.

**Habitat.** Lowland and hill primary and secondary forest, often in dense, swampy forest. Commonest at low altitudes, but recorded to 1200 m.

**Food and Feeding.** Primarily snails and earthworms; larger insects and their larvae, as well as frogs and small snakes, also reported taken. Feeds in leaf litter in manner of a thrush (Turdidae), using sideways movements of the bill to overturn leaves. Rocks used as "anvil" for smashing snail shells.

**Breeding.** Season about Mar-Nov. Domed nest loosely constructed from broad dead leaves, bamboo leaves and sticks, with platform leading to lateral entrance, 80 cm to 3 m above ground in fork of small palm. Clutch 2-3 eggs, off-white with brown spots, most numerous and finest at broad end, 32 × 26 mm; both sexes incubate, period c. 16 days, and both also care for nestlings; female broods chicks during night, even 2 days before fledging, presumably to protect them from predation by snakes; fledging period c. 16 days. Longevity in captivity over 12 years.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Fairly widespread but scarce to rare, and very shy. Rare in Tenasserim and Thailand; present in Khao Nor Chuchi Wildlife Sanctuary, Thailand. In Peninsular Malaysia was moderately common in NW (Perlis and N Kedah) in 1939, but now scarce throughout range there; present in Taman Negara National Park. Generally rare in Borneo, but reported as locally common in N (Sabah); recently reported also from SW, in Gunung Palung National Park, well outside previous known range; present in Sepilok Re-

serve. Not definitely recorded in Sumatra since end of 19th century, though there is an unconfirmed recent sight record at Mt Leuser, in Aceh; remaining lowland forest E of species' main area of distribution in Bukit Barisan has, however, been little explored ornithologically. The species' voice has only recently been recorded, making it likely that this pitta has previously been overlooked. A nest found in a forest fragment, only 50 m from where a house was being constructed, and sightings in overgrown rubber estates, scrub and thickets suggest some adaptation to human-induced habitat changes. Nevertheless, the rapid destruction of all lowland forest represents a potentially serious threat to this species. One pair has been bred successfully in captivity.

**Bibliography.** Allen (1953, 1959), Andrew (1992), Bransbury *et al.* (1994), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Dickinson *et al.* (2000), Duckworth & Kelsh (1988), Fogden (1976), Holmes (1996), Jeyarajasingam & Pearson (1999), Lambert (1990, 1992a), Lekagul & Round (1991), Lewis *et al.* (1989b), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Martyr (1997), McKelvey & Miller (1979), McLoughlin (1988), Medway (1972), Medway & Wells (1976), Medway *et al.* (1968), Porter (1933b), Riley (1938), Robson (1997b, 2000d), Robson & Komolpalin (1988), Round (1988, 2000), Round & Treesucon (1986b), Round *et al.* (1989a, 1989b), Rozendaal (1990, 1994), Showler (1992), Smythies (1986, 1999), Stattersfield & Capper (2000), Wells (1983, 1985b), Whitehouse (1988).

7. Blue Pitta

Pitta cyanea

**French:** Brève bleue      **German:** Fleckenbrustpitta      **Spanish:** Pita Azul  
**Other common names:** Lesser Blue Pitta

**Taxonomy.** *Pitta cyanea* Blyth, 1843, Arakan, west Myanmar. In past, on occasion placed in separate genus *Leucopitta*; alternatively, sometimes placed with the *Eucichla* group; however, appears to be most closely related to *P. schneideri* and *P. caerulea*. Three subspecies recognized.  
**Subspecies and Distribution.**  
*P. c. cyanea* Blyth, 1843 - E Bangladesh, NE India (Arunachal Pradesh, Assam) and Myanmar (except N) E to S China (S Yunnan) and S to Tenasserim and S Thailand, also NE Laos and Vietnam (S Tonkin S to C Annam).  
*P. c. aurantiaca* Delacour & Jabouille, 1928 - SE Thailand and SW Cambodia.  
*P. c. willoughbyi* Delacour, 1926 - C Laos to S Annam.

**Descriptive notes.** 22-24 cm; 99-120 g. Male has conspicuous flame-orange hindcrown and nape, black central crownstripe, black stripe through eye; upperparts and tail blue; innerwing and scapulars blue, outerwing black with small white spot in primaries; underparts pale grey-blue with black spots and bars; iris dark brown; bill black; feet plumbeous with flesh-coloured tinge. Female is duller, upperparts dark olive with a little blue on mantle, tail blue like male's. Dusky stripes found on upperparts of 53% of 116 adults examined (both sexes, all races). Juvenile is dark brown, mantle with pale rufous-buff streaks, breast spotted dark

brown and rufous-buff, tail dull blue, red base of bill. Race *aurantiaca* has nape more yellowish-orange; *willoughbyi* is brighter in both sexes, often some red on breast. **Voice.** Liquid "pleow-whit" or "choocoo-whip", drawn out and with sharp ending, c. 1 second long, probably by both sexes, most vocal in Apr-Oct; alarm a rasping "skeew" or "eeyow".

**Habitat.** Evergreen forest and bamboo, often with steep ravines, both in moist forest adjacent to streams and thick ground vegetation and in dry and less dense forest; also in limestone forest in Vietnam. From 60 m to 2000 m, but most often at lower altitudes.

**Food and Feeding.** Diet includes insects, insect larvae, worms, grubs and snails; stomach of a traffic casualty contained only beetles. Forages by digging in soil with its bill, like a thrush (Turdidae).

**Breeding.** Breeds May-Jun, rarely also Jul, in India and Myanmar, and in Jun-Oct in Thailand. Domed nest with side entrance loosely built from bamboo leaves, roots and debris, with platform of wet bamboo leaves, placed on rock, tree stump or ground, sometimes partly or wholly unconcealed; sometimes constructed of sticks, leaves, moss and grass and placed up to 4 m above ground in understorey or young tree. Clutch 4-5 eggs, occasionally up to 7, glossy white with dense purplish-brown and black spots and lines, 28 x 21 mm; both parents incubate, period not documented; fledging period not recorded.

**Movements.** Largely sedentary, but some local altitudinal movement likely in India and Myanmar; probably only a breeding visitor in Bangladesh.

**Status and Conservation.** Not globally threatened. Appears to be rare in India, with only a few recent records from Arunachal Pradesh, Assam, Manipur, Mizoram and Tripura. Only recent record from Bangladesh was in NE in May and Jun 1988, when some individuals seen in West Bhanugach Reserve Forest were suspected to be breeding. Status in Myanmar unknown, but fairly common in W & SE Thailand, and common in Khao Yai National Park. Very rare in S China (Yunnan). In Vietnam, located at five sites in 1991. Although generally considered rare to locally frequent, its highly secretive habits mean that it can easily be overlooked; may be more numerous than observations indicate. Not known to be hunted for food or trapped for the cagebird trade.

**Bibliography.** Ali & Ripley (1983), Ali *et al.* (1996), Cheng Isohsin (1987), Deignan (1945), Delacour & Jabouille (1940), Dickinson *et al.* (2000), Duckworth *et al.* (1999), Eames & Lambert (1994), Eames & Robson (1992), Eames, Eve & Tordoff (2001), Eames, Steinheimer & Bansok (2002), Evans & Timmins (1998), Grimmett *et al.* (1998), Harvey (1990), Hill *et al.* (2001), Kazmierczak (2000), Lekagul & Round (1991), Lewis *et al.* (1989b), MacKinnon & Philipps (2000), McClure (1974), Meyer de Schauensee (1984), Rashid (1967), Riley (1938), Ripley (1982), Robson (1994, 2000d), Robson *et al.* (1993b), Round (1984, 1988), Round & Treescuon (1983), Rozendaal (1988), Singh (1994), Smythies (1986), Stattersfield & Capper (2000), Stuart Baker (1934), Thewlis *et al.* (1996), Thompson *et al.* (1993), Wang Sung (1998), Whitehouse (1988), Wiles (1979), Yang Lan (1983).

8. Banded Pitta

Pitta guajana

**French:** Brève azurine      **German:** Bindenpitta      **Spanish:** Pita Barrada  
**Other common names:** Blue-tailed Pitta; Irene/Van den Bosch's Pitta (*irena*)

**Taxonomy.** *Turdus Guajanus* Statius Muller, 1776, Banjuwangi, eastern Java. On basis mainly of longer, graduated tail, sometimes placed in separate genus *Eucichla*, along with *P. elliotii* and *P. gurneyi*, and on occasion *P. cyanea*. Significant geographical differences in coloration and voice; race *schwaneri* possibly a separate species; the two W races may together form another species, in which *ripleyi* perhaps represents only a clinal extreme of *irena*; further study needed. Birds from W Java often recognized as race *affinis*, but considered generally inseparable from nominate. In addition, described race *bangkae*, supposedly from Bangka I, is thought to have been named from a mislabelled specimen originating probably from W Java. Four subspecies currently recognized.

**Subspecies and Distribution.**  
*P. g. ripleyi* Deignan, 1946 - S peninsular Thailand.  
*P. g. irena* Temminck, 1836 - Peninsular Malaysia (Perlis S to Johor) and Sumatra.  
*P. g. schwaneri* Bonaparte, 1850 - Borneo.  
*P. g. guajana* (Statius Muller, 1776) - Java and Bali.

**Descriptive notes.** 20-23 cm; 93-106 g (Java), 60-80 g (Borneo). Male has top and side of head black, with broad bright yellow supercilium; upperparts plain chestnut-brown, rump and tail deep blue; wings blackish-brown with white spot in primaries, some white in outer secondaries, and median and greater coverts broadly tipped white; chin and throat white, gradually becoming yellow on lower throat, dark blue band on upper breast, rest of underparts yellow with blackish barring; iris dark brown; bill black; feet purplish-pink. Female is duller, top of head brown, supercilium buffish, narrow black upper breastband, yellow on underparts paler. Dusky stripes found on blue uppertail-coverts of only 6% of 157 adults examined (both sexes, all races). Juvenile is speckled brown, some white wing-covert patches, brown tail soon becoming blue, bill with orange base and tip; sexual dimorphism evident by fledging, male showing dark brown breast with faint streaking and barring, female showing paler breast with cream-coloured spots, head darker in male. Race *irena* has deeper yellow supercilium becoming flame-orange on nape, blue underparts with orange barring on breast side, female resembles nominate male except that eyebrow is pale buff at front, becoming yellow behind eye and orange on nape; *ripleyi* resembles last, but orange usually extends from nape to near eye; *schwaneri* has large blue belly patch, female differs from nominate in yellowish eyebrow. **Voice.** Varies geographically: in Malay Peninsula a falling "pouw" and a short, whirring "kirr" or "whirr", both of an explosive quality; softer "hwow" in Sumatra; call higher-pitched in Java and Bali; in Borneo "shewo" and "hirr", repeated every 10-15 seconds, more rarely explosive "pauk" and gentler "kur-kur" or "purr".

**Habitat.** Primary forest, often near limestone cliffs; more rarely in older secondary forest, coffee plantations or heavily logged forest. Lowlands and to 1500 m.

**Food and Feeding.** Mainly insects, e.g. scarabid beetles, caterpillars, termites (Isoptera) and ants, cockroaches (Blattodea), also snails and earthworms; small orange berries also taken. Two individuals recorded to have fed on corpse of dead shama (*Copsychus*) or, possibly, on invertebrates contained therein. Forages on ground, where reported scratching with the feet in chicken-like manner.

**Breeding.** Breeds in Jun-Sept in Thailand, in Mar-Dec in Peninsular Malaysia, in Apr-Sept in Sumatra, in Jan-Jun in Java and in Mar-Aug in Borneo. Globular nest 24-30 cm in diameter, with side entrance, built of broad leaves, some skeletonized, bamboo leaves, small sticks and grass, loosely held together with rootlets and fibres, and placed low in bush or sapling or in rattan palm. Clutch 2-5 eggs, typically 3 or 4, white with rufous, brown, lavender and black spots concentrated at broad end, with underlying grey-lilac spots, mean size in Java 25 x 22 mm; laying interval in captivity (*irena*) c. 27 hours; incubation by both sexes, period 13 days; both sexes also care for chicks, which fledge after 15 days, able to feed selves after further 4 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. CITES II. As a lowland-forest species it is already rare in Thailand, where nearly all lowland forest is logged, although still 12-13 pairs/km<sup>2</sup> in a small forest patch in 1986. Situation not much better in Peninsular Malaysia, where recorded as common only in W Pahang in 1939; locally common in lowland forest in N in 1971, but in 1994 had disappeared from Panti Forest Reserve in S (Johor); fairly common in Taman Negara National Park. Rather local in Sumatra, but common in Way Kambas National Park. Uncommon to locally rather common in Java and Bali. Widely distributed but local in Borneo, where common only in Sarawak and Sabah. Has declined rapidly, not only as a result of habitat destruction but also because of the cagebird trade, in which this is among the most frequently seen pitta species. Despite its showing some tolerance of habitat alteration, forest destruction remains a threat, at least in the long term. Present in numerous protected areas, e.g. Khao Nor Chuchi Wildlife Sanctuary (Thailand), Ujung Kulon and Balura National Parks (Java), and Bali Barat National Park (Bali). Has been bred successfully in captivity.

**Bibliography.** Andrew (1985, 1992), Baars (1984), van Balen (1999), Beckett (1975), Bransbury *et al.* (1994), Bruning (1977), Danielsen & Heegaard (1995), Davison (1995), Deignan (1946), Diamond *et al.* (1987), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Duckworth & Kelsh (1988), Ellis (2002), Fogden (1976), Glenister (1971), Harrison (1974), Hellebrekers & Hoogerwerf (1967), Holmes (1997), Hoogerwerf (1947, 1963a), Hornskov (1987), Jeyarajasingam & Pearson (1999), Lambert & Collar (2002), Lekagul & Round (1991), Lewis *et al.* (1989a, 1989b), Lim Kim Seng (1994), MacKinnon (1988), MacKinnon & Philipps (1993), Mann (1988), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986, 1996), Meyer de Schauensee (1958), Mitsch (1990), Nash & Nash (1988), Nilsson (1989, 1990), Parrott & Andrew (1996), Porter (1932), Riley (1938), Rinke & Marcordes (2002), Robson (2000d), Roles (1974), Round (1988), Round & Treescuon (1986b), Sargeant (1997), Showler (1992), Silvius & Verheugt (1986), Smythies (1986, 1999), Sody (1989), Stattersfield & Capper (2000), Thompson (1966), Thomsen *et al.* (1992), Vernon (1974), Wells (1975, 1985b, 1990b), Whitehouse (1988).

9. Bar-bellied Pitta

Pitta elliotii

**French:** Brève d'Elliot      **German:** Grünscheitelpitta      **Spanish:** Pita de Elliot  
**Other common names:** Elliot's Pitta

**Taxonomy.** *Pitta elliotii* Oustalet, 1874, Cochinchina. On basis mainly of longer, graduated tail, sometimes placed in separate genus *Eucichla*, along with *P. guajana* and *P. gurneyi*, and on occasion *P. cyanea*. Monotypic.

**Distribution.** Extreme E & SE Thailand, Laos, Vietnam and Cambodia.

**Descriptive notes.** 19-21 cm; 85-97 g. Male has top of head and nape blue-green, bluer on sides, broad black band from lores to nape; upperparts dark green, faintly tinged blue, tail bright blue-violet; chin and upper throat white, lower throat and upper breast blue-green, rest of underparts barred yellow and black, dark blue belly centre; iris brown to dark brown; bill dark red-brown to black; feet fleshy-coloured. Female has top of head and nape buffish-brown with central crown greenish, throat and upper breast dirty buffish, rest of underparts less yellow than male, no blue on belly. Dusky stripes found on upperparts of 37% of 27 adults examined (both sexes). Juvenile is dark brown, darker on head side, spotted buff above and on breast, pale throat, mostly orange bill. **Voice.** Common call a cheerful trisyllabic whistle, "tu-wi-whil", "per-ur-wu", "hwt-whit-too" or "chawee-wu", repeated every c. 9 seconds; occasionally a mellow "hhwee-bwba"; loud, exclamatory "skew", "jeeow" or "jow" as alarm; soft "coo" by adults approaching nest, chicks answering with soft "chip" and tweets.

**Habitat.** Evergreen and semi-evergreen forest with rich understorey, often on limestone; also secondary forest and logged areas. Also moist riverine primary forest in S Laos. Often in bamboo-dominated understorey in flat forest, but also in dry sloping forest where understorey dominated by fan palms. Occurs from sea-level to 800 m.

**Food and Feeding.** Only termites (Isoptera), a 2-cm-long caterpillar and earthworms reported. Pecks at ground, turns over leaves; once seen repeatedly digging in soil and leaf litter.

**Breeding.** Season probably Apr-Jun, but very few records. Domed nest 18 × 24 × 20 cm, with

side entrance and a "doormat" 13 × 12 cm, built of twigs, leaves of palm, bamboo and rattan, some leaves skeletonized, lined with finer leaf veins, and placed low down in palm or to 5 m in tree. Clutch 2-4 eggs, creamy white and unmarked, or spotted brown at broad end, 29 × 22 mm; incubation and nestling periods undescribed; both parents feed fledglings.

**Movements.** Apparently sedentary.

**Status and Conservation.** Not globally threatened. Fairly common to common. Until 1926 was known only from two skins, and in period up to 1988 only few were reported; was thought to be very rare and, with large areas of lowland forest having been destroyed, was declared a threatened species. In 1988, however, it was found by ornithologists to be common in Vietnam at Cuc Phuong National Park, Ky Son, Kon Ha Nung, Buon Luoi and Kon Cha Rang, in C Annam, and at Son Tung, in N Annam; also seen in Nam Bai Cat Tien National Park, in S Vietnam, in 1994; also present in Bach Ma National Park. In S Laos, 1 male/75 m found in a semi-evergreen forest in 1993, and another observer reported the species as common in that part of the country; but said by others to be potentially at risk in 1995/96; present in Phou Xang and Xe Pian National Biodiversity Conservation Areas. Scarce to rare in Thailand, where few records from SE possibly derive from trade skins from elsewhere. No human persecution reported. Rediscoveries of this pitta in recent years suggest that it may be under-recorded through much of range, but extensive deforestation could well pose a major threat to its long-term survival.

**Bibliography.** Campey (1996), Collar & Andrew (1988), Collar *et al.* (1994), Delacour (1929, 1930b), Delacour & Jabouille (1928, 1940), Dickinson *et al.* (2000), Duckworth (1996), Duckworth *et al.* (1999), Eames (1996a, 1996b), Eames & Erierson (1996), Eames & Robson (1992), Eames, Eve & Tordoff (2001), Eames, Lambert & Cu (1994), Inskipp *et al.* (1996), King *et al.* (1975), Le Trong Trai & Richardson (1999a), Lekagul & Round (1991), Mountfort & Arlott (1987), Nguyen Cu *et al.* (2000), Robson (2000d), Robson, Eames, Nguyen Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Round (1988), Rozendaal (1988, 1989), Rozendaal & Nguyen Cu (1989), Stattersfield & Capper (2000), Stepanyan (1993, 1995), Strange (2000), Thewlis *et al.* (1996).

## 10. Gurney's Pitta

### *Pitta gurneyi*

**French:** Brève de Gurney

**German:** Goldbrustpitta

**Spanish:** Pita de Gurney

**Other common names:** Black-breasted Pitta

**Taxonomy.** *Pitta Gurneyi* Hume, 1875, southern Tenasserim, Myanmar.

On basis mainly of longer, graduated tail, sometimes placed in separate genus *Eucichla*, along with *P. guajana* and *P. ellioti*, and on occasion *P. cyanea*. Monotypic.

**Distribution.** Peninsular Thailand in Krabi Province (Khao Nor Chuchi), and possibly extreme S Myanmar (S Tenasserim).

**Descriptive notes.** 21 cm; 57-86 g. Male has black head, glossy ultramarine-blue central crown to nape; upperparts plain warm brown, longest uppertail-coverts and tail shining blue; chin white, and variable amount of white on centre of throat; upper breast and flanks orange-yellow, flanks barred black, rest of underparts black; iris dark brown; bill black; feet dull flesh. Female has crown and nape yellow-buff, underparts variably barred black and buffish to rufous-buffish, central belly unbarred. Dusky stripes found only on blue uppertail-coverts of 7% of 69 adults examined (both sexes). Juvenile is dull dark brown, crown and nape with golden-ochre stripes, breast streaked buffish, bill with orange tip. **Voice.** Heard in Mar-Jun, a short, explosive "lilip", female call shorter "lup"; alarm of both sexes "skyeew"; low-pitched "hoo" also reported.

**Habitat.** Inhabits lowland semi-evergreen and secondary riverine rainforest dominated by dipterocarp trees and with dense understorey of bamboo, palms and vines; also rubber plantations with similar understorey or with native trees and palms; also degraded forest fragments. Strong preference for vicinity of small streams or gulleys where moist conditions prevail throughout year. Has been recorded also in swamp-forest when not breeding. Lowlands to 160 m.

**Food and Feeding.** Variety of prey reported: annelid worms, many kinds of insects and their larvae, spiders, slugs and snails, and small frogs.

Use of anvils not reported. Exposes concealed prey by tossing aside leaves with lateral flicks of bill.

**Breeding.** Season late Apr-Oct, with peak in Jun. Domed nest 19-20 cm in diameter, with side entrance 10 × 7 cm, built of bamboo leaves, broadleaves and sticks, lined with fine black rootlets, and situated low in tree or rattan. Clutch 3-4 eggs, occasionally 5, glossy cream-white, spotted and freckled with pale to very dark inky-purple spots and with underlying grey-lilac spots, 26 × 21 mm; both parents incubate, only female at night, incubation period not known; both also feed chicks, which leave nest at 14-15 days. Fledging success at three nests 27-3%.

**Movements.** Resident.

**Status and Conservation.** **CRITICAL.** CITES I. Extremely rare and local. Considered common in S Myanmar (Tenasserim) in late 19th century, but not recorded since 1914, and reported massive deforestation by logging companies since 1988 suggests little chance of its survival there. Was also common and more widespread in peninsular Thailand up to 1915, but apparently declined thereafter and, after specimen was collected in 1952, the species was not seen again for 34 years (except for a few in the wild-bird trade). In 1986, it was rediscovered in one of Thailand's last remnants of lowland rainforest at Khao Nor Chuchi Reserve (also called Khao Pra-Bang Kham Non-hunting Area), in Krabi Province; in the following year 17 pairs were located, and in 1988 at least 40 pairs, of which a few were in scattered forest fragments in Khlong Phraya Wildlife Sanctuary and Khao Phanom Bencha National Park; by 1992, however, the population around Khao Nor Chuchi (upgraded to a Wildlife Sanctuary in 1993) was estimated at 25-35 pairs at most, with a few additional ones at Khlong Phraya. Surveys in 2000 and 2001 indicated that this species' total world population is no more than c. 30 individuals, with 11-12 territories known to survive at Khao Nor Chuchi and a further two at nearby Tambon Aw Tong, in Trang. Despite intensive fieldwork, this pitta has not been found in other suitable lowland forest, but the fact that it is a relatively silent species makes it extremely difficult to census; in 39 hours of observations at a nest, only nine calls were heard. Notwithstanding an enormous conservation effort involving the local people, including e.g. the adoption of sustainable agriculture in the Khao Nor Chuchi project area, clearance of forest persists. Moreover, the planting in illegally cleared forest patches of oil palms (*Elaeis guineensis*), which are increasingly taking over from less profitable rubber plantations, poses major problems; no pitta can live there, because no natural cover remains among the palms. Trapping for the cagebird trade was a great threat until the early 1990s; although it appears almost to have ceased, some hunting and trapping still take place in the sanctuary. A survey in 2001 confirmed that protection and law enforcement at Khao Nor Chuchi is effectively non-existent. Subsequent conservation initiatives include special training of Thai Royal Forestry Department rangers in order to achieve more effective patrolling at Khao Nor Chuchi; the proposed utilization of a plot of c. 16 ha for a pilot attempt at replanting, with local villagers paid to do the work and to protect the plot; and a programme of environmental awareness aimed at school-children in the immediate area of the Khao Nor Chuchi site. Clearly the species' current situation appears desperate, though there may be some small chance for its survival, as it appears to prefer some stages of advanced, well-watered secondary regrowth.

**Bibliography.** Aitchison (1993), Anon. (1989d, 2000b, 2000c), Banwell (2000), Clement (2001), Collar (1986, 2000, 2001, 2002), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Round & Wells (1986), Deignan (1963), Dickinson *et al.* (2000), Erritzoe (2001), Ferganbauer-Kimmel (1986), Fuller (2000), Gould (1986), Green & Hirons (1991), Gretton (1987a, 1987b, 1988), Gretton & Robson (1987), Gretton *et al.* (1993), Hocombe (1989), Jepson & Grimmett (2002), King, W.B. ## 11. Blue-headed Pitta

### *Pitta baudii*

**French:** Brève à tête bleue

**German:** Rotrückenpitta

**Spanish:** Pita Cabeciazul

**Taxonomy.** *Pitta baudii* S. Müller and Schlegel, 1839, south Borneo.

Formerly placed in monotypic genus *Iridipitta*, on basis of dark purplish-blue underparts, unique among pittas; alternatively linked with *Eucichla* group. Monotypic.

**Distribution.** Borneo.

**Descriptive notes.** 16-17 cm; male 56-69 g, female 65-76 g. Male has glossy blue forehead to nape, black lores and facial mask, maroon-red upperparts, blue tail and uppertail-coverts; most upperwing-coverts black, flight-feathers blackish-brown, prominent white wingband; chin and throat white, breast black, rest of underparts dark purple-blue; iris dark brown; bill black; feet grey-blue to horn or flesh-coloured. Female has top of head and upperparts rufous to cinnamon-brown, palest on head, throat greyish-buff, rest of underparts dull orange-buff to cinnamon. Dusky stripes found on blue rump of 18% of 39 adults examined (both sexes). Juvenile is like

female but duller, breast dark brown, rest of underparts marbled dull brown and golden ochre, bill tip red. **VOICE.** Soft descending "ppor-wi-il"; or shortened "ppor-or"; alarm call of female a drawn-out nasal "hwee-ouu".

**Habitat.** Lowland primary forest and older secondary forest, also logged forest, often with a river nearby. From sea-level to 600 m; an unconfirmed record at 1200 m.

**Food and Feeding.** Diet consists of earthworms, beetles, ants, Orthoptera (grasshoppers, crickets), caterpillars and other soft-bodied arthropods. Feeds among leaf litter by turning over leaves.

**Breeding.** Few records. Single nest found in early May, specimens in breeding condition in Mar-Jun and juveniles seen in Jul to mid-Oct, suggesting season Mar-Oct. Nest was domed, built of matted dead leaves and surrounded by herbs, and placed 50 cm above ground on top of soil mound created by root system of fallen tree. Clutch 2 eggs, glossy white with band of irregular purple-brown spots around widest point; male seen incubating on two occasions.

**Movements.** Apparently sedentary.

**Status and Conservation.** **VULNERABLE.** Locally common but patchily distributed. Occurs in several protected areas: Gunung Palung and Tanjung Puting National Parks and Barito Ulu Reserve, in Kalimantan, Sepilok, Tabin and Gunning Lotung/Malimau Reserves, in Sabah, and Gunung Mulu National Park and Samunsam Reserve in Sarawak. Reported as common in recent years e.g. in C Kalimantan, where up to three calling males found in a forest of 1 km<sup>2</sup>; but other sources suggest that it is rare in Kalimantan and much commoner in N Borneo. Most birds recorded from E Sabah, where very common at Kalabakan and Danum Valley; at one site in N Borneo at least 2 pairs/km<sup>2</sup>. Extremely rare in Sarawak. There are still some lowland forests left in Borneo, which in short term provide grounds for some optimism; on the other hand, the continuing rapid deforestation and uncontrolled fires give cause for concern over the future prospects of this beautiful lowland-forest species. Appears to adapt to some degree to habitat modified by man. No reports of hunting, nor of capture for live-bird markets.

**Bibliography.** Andrew (1992), Bransbury *et al.* (1994), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Davison (1980), Dekker & Dickinson (2001), Dickinson *et al.* (2000), Duckworth & Kelsh (1988), Dutton (1990), Elter (1986), Fogden (1976), Holmes (1997), Holmes & Nash (1991), MacKinnon & Philipps (1993), Mitra & Sheldon (1993), Müller & Schlegel (1839), Pope (1997), Showler (1992), de Silva (1981), Smythies (1999), Stattersfield & Capper (2000), Strange (2000), Thompson (1966), Wells (1985b), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Noor & Noor (1991).

## 12. Superb Pitta

### *Pitta superba*

**French:** Brève superbe

**German:** Schwarzückenpitta

**Spanish:** Pita Soberbia

**Other common names:** Black-backed Pitta

**Taxonomy.** *Pitta superba* Rothschild and Hartert, 1914, Manus Island, Admiralty Islands.

Relationships uncertain. Has sometimes been considered closest to *P. maxima* and *P. steerii*, or to form a superspecies with those and *P. sordida*, but morphological differences appear to be too great for this treatment to be appropriate; detailed DNA studies required. Monotypic.

**Distribution.** Manus I, in Admiralty Is.

"hwouu-whoou", often given from branch 2-7 m up; chicken-like "quark", mostly from ground, is audible at close range.

**Habitat.** Primary and secondary hilly rainforest, as well as scrub around village gardens and bamboo scrub. Recorded only to 100 m, but probably also inhabits higher altitudes.

**Food and Feeding.** Not documented. Said by local villagers to eat snails after smashing them on stones; this was corroborated by a discovery by ornithologists of a flat stone with snail-shell fragments nearby.

**Descriptive notes.** 21-22 cm. Glossy black, except for large conspicuously iridescent azure-blue and green upperwing-coverts, flight-feathers edged green, and bright red central lower breast, belly and undertail-coverts; iris dark brown; bill black; feet flesh-coloured to horn. Female is smaller and slightly duller than male, red on underparts less bright. Dusky stripes found on blue wing patch of 43% of 54 adults examined (both sexes). Juvenile is dull blackish-brown, blue on wings less extensive and duller, red of underparts replaced by dull pinkish, bill tipped orange-red. **VOICE.** A rising and falling "coo-coo", also described as

**Breeding.** Only known nest with eggs was found in Oct, but five males and eight females in breeding condition in Dec-Jan and juveniles reported in Sept-Oct; presumably breeds in all months, like other birds on Manus. Domed nest with side entrance, constructed of fibres, rootlets, bamboo and other leaves, moss and small twigs, lined with rootlets and fibres. Clutch 2 eggs, glossy white with deep pores and spotted purplish-brown with underlying mauve-grey, 34 × 26 mm.

**Movements.** Sedentary.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Admiralty Islands EBA. Little information on status. Recent survey suggested a total of 1000 calling individuals on Manus (1943 km<sup>2</sup>), but this figure was based on just three calling birds within area of 3.5 km<sup>2</sup> around the village of Rossun; this estimate is considered of doubtful reliability in view of inadequate knowledge of the species' habitat preferences, calling periods and general breeding density. Only a very small part of Manus has been studied so far. Introduced cats and dogs, as well as the apparently native brown tree snake (*Boiga irregularis*) and the ground boa (*Candoica aspera*), are believed to be the greatest threats. Although much of Manus has already been logged or is under logging concessions, some forest cover still remains in 80% of the island; indeed, local people are proud of their forest and most are against logging, preferring instead selective felling, which may give some cause for optimism. Further research and survey work required.

**Bibliography.** Coates (1990), Coates & Peckover (2001), Collar & Andrew (1988), Collar *et al.* (1994), Dutton (2000), Dutton & Newman (1991), Eastwood (1995), Eastwood & Gregory (1995), Fletcher (2000a), Gregory (1995b), Hicks & Hicks (1991), Mayr (1955), Mayr & Diamond (2001), Rothschild & Hartert (1914), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 13. Ivory-breasted Pitta

### *Pitta maxima*

**French:** Brève d'Halmahera

**German:** Weißbrustpitta

**Spanish:** Pita de Halmahera

**Other common names:** Great/Halmahera/Moluccan Pitta

**Taxonomy.** *Pitta maxima* S. Müller and Schlegel, 1845, Halmahera.

Relationships uncertain. Has sometimes been considered closest to *P. superba* and *P. sordida*, or to form a superspecies with those and *P. steerii*, but morphological differences appear to be too great for this treatment to be acceptable; further DNA studies required. Two subspecies recognized.

**Subspecies and Distribution.**

*P. m. maxima* S. Müller & Schlegel, 1845 - Halmahera, including islands of Kasiruta and Bacan, possibly also Mandioli and Obi.

*P. m. morotaiensis* van Bemmelen, 1939 - Morotai.

**Descriptive notes.** 25-28 cm; male 172-206 g, female 166-172 g. Adult has glossy black head, upperparts and tail, shining blue and green upperwing-coverts, black wings with white band on primaries, inner flight-feathers edged green; chin and throat black, rest of underparts ivory-white with large patch of black-based red feathers on central lower breast, belly and undertail-coverts; iris brown; bill black; feet pale flesh-coloured. Sexes alike. Dusky stripes found only on blue and green wing-coverts of 34% of 64 adults examined (both sexes, both races). Juvenile is like adult but duller, without gloss, less bright below. Race *morotaiensis*

is slightly larger, has darker blue wing-coverts, broader white wingband, edges of inner flight-feathers darker blue-green. **VOICE.** Main call a loud, far-carrying, drawn-out "phwee phweeecoou" of c. 1.5 seconds' duration, also transcribed as "wok-wow", "wi-whooou" or "werrhh-wuuhhh"; has been likened to a call of Tawny Owl (*Strix aluco*) or a human wolf-whistle.

**Habitat.** Lowland forest, second growth, often in limestone and karst areas with luxuriant ground vegetation; occasionally in overgrown coconut plantations. To 650 m on Halmahera and 500 m on Kasiruta; to 800 m on Morotai.

**Food and Feeding.** No documented information. Earthworms and caterpillars reported by local people as being eaten by this species; also, an "anvil" with broken snail shells thought probably the result of this pitta's feeding.

**Breeding.** Few data: nests with single egg found in May-Jul, juvenile in early Feb and males with enlarged testes in May, Jun and Nov; probably breeds throughout year. Domed nest built of blackish sticks, dead and skeletonized leaves and fine roots, with small platform of sticks and large dead leaves at side entrance, with moss often hanging over the whole structure; placed on ground between buttress roots of large tree, giving appearance of a ball of fallen plant debris. Clutch size unknown; eggs white with few dark red-brown lines and large spots with grey-lilac underlying spots, c. 33 × 27 mm; no information on incubation and fledging periods.

**Movements.** Sedentary.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Northern Maluku EBA. Locally common in all forest and other well-vegetated habitats on Halmahera except NE coast, where uncommon; common on Kasiruta; rare and very local on Bacan. Presence on Mandioli, off SW coast of Bacan, uncertain, but considered likely to occur there. Status on Obi also unknown: probably heard in early 1990s but confirmation of identification required, while earlier report from that island may have involved an escaped individual. No recent reports from Morotai (*morotaiensis*). Not known to be hunted for food or for the cagebird trade.

**Bibliography.** Andrew (1992), Andrews (1988), Babbington (1992), Bostock & Sujatnika (1993), Buck (1987), Coates & Bishop (1997), Dickinson *et al.* (2000), Eastwood (1998), Heinrich (1956), Inskipp *et al.* (1996), Lambert (1994), Lambert & Yong (1989), MacKinnon *et al.* (1995), Poulsen & Lambert (2000), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Strange (2001), Sujatnika *et al.* (1995), White & Bruce (1986).

## 14. Blue-banded Pitta

### *Pitta arquata*

**French:** Brève à bandeau

**German:** Blaubauchpitta

**Spanish:** Pita Bandeada

**Other common names:** Necklaced Pitta

**Taxonomy.** *Pitta* (*Phoenicocichla*) *arquata* Gould, 1871, Borneo.

Species name frequently spelt as *arcuata*, by reason of long-established usage following emendation made three years after species was first described; however, original spelling of name must stand. Monotypic.

**Distribution.** N half of Borneo, S to about Mt Penrisen, Barito Ulu and R Mahakam.

**Descriptive notes.** 15 cm; 50–58 g. Male has forehead to nape and side of neck scarlet, a glistening sky-blue postocular stripe, dark green-blue upperparts, narrow line of sky-blue on wing, tail dull blue; side of head and throat orange-rufous, rest of underparts scarlet, glossy sky-blue breastband like a necklace; iris red-brown to grey; bill blackish, tip and lower mandible with reddish tinge; feet blue-grey to plumbeous. Female is similar, but upperparts dark olive-green, tail grey-blue. Juvenile is plain brown, mottled grey-brown and buffish on side of head and throat, sometimes a few pinkish feathers on underparts, bill with pale

tip and orange gape, feet grey. **Voice.** Call is a monotone, single, fluty whistle of 2–3 seconds' duration.

**Habitat.** Forest, often with many fallen trees and bamboo stands. Commonest at 600–1200 m, but recorded from 150 m to 1500 m.

**Food and Feeding.** Ants and other insects. No information on foraging behaviour.

**Breeding.** Season Jan–Sept, with peak in Mar–Aug. Globular nest built of dead leaves, grass and fibres, placed 0.5–2.5 m above ground in tree. Clutch probably 2 eggs but few records, glossy white with grey and brown spots at broader end, c. 30 × 21 mm; no information on incubation and fledging periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common. Uncommon in Sarawak, and rarer than the other pittas in Sabah. Locally common in Kalimantan, e.g. seen or heard on 19 occasions between Jul and Sept 1989 in Barito Ulu region (C Kalimantan), and common on Mt Penrisen (in W), but found to be scarce, rare or absent by many authors. Present in Danum Valley Conservation Area. No reports of this species being traded in the live-bird market, and no other known human threats at present.

**Bibliography.** Andrew (1992), Bransbury *et al.* (1994), Davison (1980), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Duckworth & Kelsh (1988), Dutson (1990), Fogden (1976), Holmes (1997), Inskipp *et al.* (1996), MacKinnon & Phillipps (1993), Pope (1997), Showler (1992), Smythies (1957, 1999), Stattersfield & Capper (2000), Voous (1961), Wells (1985b), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Noor & Noor (1991).

## 15. Garnet Pitta

### *Pitta granatina*

**French:** Brève grenadine

**German:** Granatpitta

**Spanish:** Pita Granate

**Other common names:** Red-headed Scarlet Pitta; Black-headed/Black-and-crimson Pitta (*ussheri*)

**Taxonomy.** *Pitta granatina* Temminck, 1830, Pontianak, Borneo.

Forms a superspecies with *P. venusta* and sometimes considered conspecific, but differs in structural and plumage characters, in altitudinal preference, and in vocalizations. Alternatively, race *ussheri* has been treated separately as a race of the latter; also, more recently, as a distinct species on basis of different vocalizations and appearance and lack of extensive hybridization where its range meets that of present species, but plumage and vocal differences appear too slight to support this treatment and hybrids are considered to be adequately documented. Three subspecies currently recognized.

**Subspecies and Distribution.**

*P. g. coccinea* Eyton, 1839 - extreme S Myanmar (Tenasserim), extreme S peninsular Thailand, Peninsular Malaysia and E Sumatra.

*P. g. ussheri* Gould, 1877 - N Borneo (S to R Lawas and R Merapok in W and to R Sembakung and R Sesayap in E).

*P. g. granatina* Temminck, 1830 - Borneo (except N).

**Descriptive notes.** 15–16 cm; 53–70 g. A small pitta with mostly black head, dark red hindcrown and nape, bright sky-blue postocular stripe; upperparts glossy black with purple wash, bluer rump, dark blue tail, shining blue upperwing-coverts; throat and upper breast purple-black, rest of underparts red; iris brown to blue; bill black; feet plumbeous purplish-blue to pinkish-grey. Sexes alike. Juvenile is mostly plain brown, paler below, with some dull blue in wings and tail, orange base and tip of bill. Race *coccinea* has red on head extending to forecrown, upperparts more blue, red on underparts mottled with black; *ussheri*

has no red on head. **Voice.** Call a drawn-out monotone and far-carrying whistle of 1.5 seconds' duration; also low purring sound, "prrr, prrr, prrr", when two birds meet.

**Habitat.** Found in both dense primary forest and secondary to heavily logged forest, often swampy. Lowlands to 300 m, locally to 500 m in Borneo.

**Food and Feeding.** Insects, including ants, beetles, wood grubs, cockroaches (Blattodea), once an orthopteran; also small snails; seeds from fruit also found in stomachs. Probes leaf litter and damp soil, often around fallen branches and logs; occasionally forages on logs.

**Breeding.** Mar–Aug; from early Feb in N Borneo. Domed nest with side entrance, built of twigs, fibres and dead and skeletonized leaves, and placed on ground. Clutch 2 eggs, glossy white with red-brown spots and dots and underlying grey-lilac spots, c. 28 × 20 mm. No information available on incubation or fledging periods.

**Movements.** Sedentary.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon to locally common in Peninsular Malaysia; present in several protected areas, e.g. Taman Negara National Park, and Pasoh and Panti Forest Reserves. Rare in Thailand; not reported from Tenasserim for over 100 years; extinct in Singapore since 1950. Probably scarce in Sumatra, but few recent observations made; until recently was known only from N part of E coast S to Medan, but since then seen farther S (to at least Jambi) and also in SE corner (Way Kambas National Park); probably occurs throughout E coastal lowlands. Widely distributed and locally common in Borneo; race *ussheri* occurs in Danum Valley Conservation Area and Sepilok Reserve. Primary forest already almost totally destroyed in all parts of its range, but this species readily accepts altered and heavily degraded or logged habitats so long as forest patches and thickets of secondary growth remain. No known exploitation for food or the cagebird trade.

**Bibliography.** Bransbury *et al.* (1994), Castelletta *et al.* (2000), Collar *et al.* (2001), Danielsen & Heegaard (1995), Davison (1980, 1995), Delacour (1946), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Fogden (1976), Hislop (1956), Holmes (1973, 1996, 1997), Holmes & Burton (1987), Holmes & Nash (1991), Inskipp *et al.* (1996), Jan & Galdikas (1987), Jeyarajasingam & Pearson (1999), Lambert & Collar (2002), Lekagul & Round (1991), Lewis *et al.* (1989b), MacKinnon & Phillipps (1993), Mann (1988), van Marle & Voous (1988), McClure (1998), McGowan (1998), Medway & Wells (1970, 1976), Mitra & Sheldon (1993), Nash & Nash (1988), Parrott & Andrew (1996), Pearson (1975a), Pope (1997), Porter (1932), Riley (1938), Robson (2000d), Round (1988), Rozendaal (1994), Showler (1992), Smythies (1957, 1986, 1999), Stattersfield & Capper (2000), Strange (2000), Stressemann (1938), Wells (1970, 1972, 1985b), Wells *et al.* (1979), Whitehouse (1988), Wilkinson, Dutson & Sheldon (1991), Wong (1985).

## 16. Graceful Pitta

### *Pitta venusta*

**French:** Brève gracieuse

**German:** Maronenrückenpitta

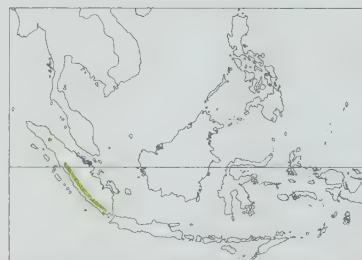

**Spanish:** Pita Graciosa

**Other common names:** Black-crowned (Garnet)/Black-and-scarlet/Sumatran Pitta

**Taxonomy.** *Pitta venusta* S. Müller, 1836, western Sumatra.

Forms a superspecies with *P. granatina* and has been considered conspecific, but differs in structural and plumage characters, in altitudinal preference, and in vocalizations. Alternatively, only race *ussheri* of latter has been included as a race of present species on account of head coloration, but other plumage features and also tail length differ considerably. Monotypic.

**Distribution.** Highlands of Sumatra.

**Descriptive notes.** 18 cm. Blackish-maroon head with bright sky-blue postocular stripe; upperparts, wings, throat and upper breast dark brown with purplish tinge, upperwing-coverts faintly edged violet-blue; long tail dark brown; lower breast and belly scarlet; iris dark brown; bill black; feet purple-black or pale blue. Sexes alike. Juvenile is plain dark brown, postocular stripe buffish, iris greyish, bill tipped red, feet pinkish-grey. **Voice.** Produces low mournful whistle of 1.3–2 seconds' duration, lower-pitched than that of *P. granatina*.

**Habitat.** Moist dark forest with ravines and

dense understorey. From 400 m to 1400 m, occasionally 1600 m.

**Food and Feeding.** Insects, small snails, small bugs (Hemiptera), worms and seeds recorded. Foraging behaviour poorly documented; feeds on ground, sometimes on top of fallen logs.

**Breeding.** Only one nesting record, in May, and few observations of juveniles suggest season May–Jul, but possibly Feb–Oct. Nest domed, loosely constructed of dead leaves and bamboo leaves, fine roots and decayed fibres and moss, placed 60 cm above ground among leaves of orchid growing on trunk of fallen tree. Clutch 2–3 eggs, dull creamy with buffish and dark brown spots, freckles and scratchy lines and underlying grey-lilac spots, c. 23 × 19 mm; no other information.

**Movements.** Presumably resident, though may make local altitudinal movements.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Sumatra and Peninsular Malaysia EBA. Rare and apparently very local, and probably declining. Known from few localities, and records infrequent, even taking into account its skulking behaviour and the few ornithological visits to the Sumatran uplands. Occurs in Kerinci-Seblat and Bukit Barisan Selatan National Parks; recent records from Rimbo Kulit Manis in 1985, and from Mt Kaba, Liwa-Krui, Tandai (in Kerinci-Seblat National Park) and below Bukit Tapan in latter half of 1990s. Forest destruction, degradation and fragmentation are the main threats; almost all lowland forest within the species' range already destroyed and probably c. 40% of montane forest lost, mostly as a result of shifting cultivation. Owing to rapidly growing human population in Sumatra and the continuing rapid rate of deforestation, even within protected areas (especially Kerinci-Seblat National Park), there is an urgent need for more field data in order to provide a basis for formulation of the necessary conservation strategy. Effective management and enforcement of laws relating to protected areas considered essential. Not known from the cagebird trade; this pitta has been legally protected since 1931, but hunting with air-guns and ground snares seems to be a problem.

**Bibliography.** Andrew (1992), Collar *et al.* (2001), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Ellis (2002), Holmes (1996), Inskipp *et al.* (1996), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Martyr (1997), Müller & Schlegel (1839), Robinson & Kloss (1918b, 1924), Robson (1996a, 1997b), Rozendaal (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Tobias (1995).

## 17. African Pitta

### *Pitta angolensis*

**French:** Brève de l'Angola **German:** Angolapitta **Spanish:** Pita Angoleña  
**Other common names:** Angolan Pitta

**Taxonomy.** *Pitta angolensis* Vieillot, 1816, Angola.

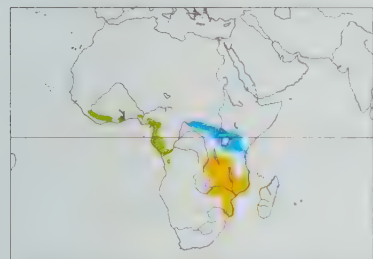

Forms a superspecies with *P. reichenowi*, and sometimes regarded as conspecific on basis of apparent intermediate birds from Cameroon and S Congo; doubts have been expressed, however, over identification of such birds (which could possibly have been nominate race of present species), and there seems little evidence of intergradation where the ranges of the two species approach each other. Three subspecies recognized.

#### Subspecies and Distribution.

*P. a. pulih* Fraser, 1843 - Sierra Leone and SE Guinea E to W Cameroon.

*P. a. angolensis* Vieillot, 1816 - SW Cameroon S to NW Angola.

*P. a. longipennis* Reichenow, 1901 - breeds from SE Zaire and SE Tanzania S to E Zambia, N & E Zimbabwe, S Mozambique and extreme NE South Africa; migrates N to region from S Central African Republic and N & NE Zaire E to S Kenya and N Tanzania.

**Descriptive notes.** 18-20 cm; male 79-92 g, female 81-98 g. Has black head, broad buffish-ochre supercilium, rear supercilial feathers slightly paler and erectile; upperparts bright green, rump and tail-coverts sky-blue, tail black; area near shoulder and wing-coverts sky-blue and violet; flight-feathers blackish, tips paler, white patch on primaries; throat white with pink wash, breast and flanks deep buff, often with golden-green wash, belly and undertail-coverts scarlet; iris red-brown to grey-brown; bill black; feet range from pinkish to greyish-white. Sexes alike. Dusky stripes found on green and blue upperparts of 21% of

56 adults examined (both sexes, all races). Differs from *P. reichenowi* in buff, not green, breast, pinkish throat, brighter green upperparts. Juvenile is much duller and browner than adult, with less blue in plumage, golden-buff supercilium becoming white behind eye, pink belly and vent, orange bill with black central band. Race *longipennis* is larger, wings longer and more pointed, supercilium unicoloured or almost so, plumage generally brighter and slightly paler; *pulih* is smallest, supercilium clearly bicoloured ochre and pale buff, red on belly more extensive, white wing patch smaller, blue in wing-coverts variable. Voice. Main call a short, loud, sharp "ouit" or "wheet" preceded by mechanical "prrrt" believed to be produced by rapid wing-flapping, the whole also rendered as e.g. "ffrueep" or "ffrueep"; also frog-like "(g)rk" and grunts when not breeding, including by migrants, and a hoarse "hggg" apparently as alarm; in captivity, also low "skeow".

**Habitat.** Semi-deciduous and evergreen rainforest, thickets and swampy localities, occasionally deciduous scrub, all with dense undergrowth; non-breeding migrants also in dry subhumid forest with clearings in E Africa (Kenya). Lowlands and hills to 1000 m.

**Food and Feeding.** Insects, including termites (Isoptera), ants, beetles, caterpillars and grubs; also snails, and earthworms and millipedes (Diplopoda). Forages on the ground among leaf litter, especially near ant and termite nests. Stands motionless for up to 5 minutes, watching for prey, before moving in long hops to a nearby spot; also flicks aside leaves with bill, or sweeps aside leaf litter with bill and then pauses briefly to scan ground, holding head to one side in manner of a thrush (Turdidae). When prey located, makes forward lunge to seize it with the bill.

**Breeding.** In W Africa, breeds in Sept in Sierra Leone, Mar-Sept in Liberia, Jul in Ghana, Sept-Oct in Cameroon, Nov in Angola; in E, Nov-Apr in Tanzania and mostly to Feb farther S. Maintains territory of 3000-3600 m<sup>2</sup>. Domed nest 25 × 35 × 20 cm, with side entrance 7-8 cm wide and sometimes with platform in front, built of dead leaves, some skeletonized, and twigs, often with spines, and lined with finer twigs, rootlets and tendrils, the whole rather untidy and loosely built; placed 2-8 m up in usually thorny tree. Clutch 3 eggs, occasionally 1 or 4, dull creamy white with irregular dark brown, grey-brown and underlying grey-lilac spots, blotches and scrawls, most at blunter end, average size in Zambia c. 27 × 23 mm; no information on incubation and fledging periods.

**Movements.** W African populations apparently largely sedentary, but records of race *pulih* killed at windows on Sierra Leone coast in May and from gardens in coastal Liberia in Oct, as well as others seen at artificial lights in Nigeria, suggest possible local movements or true migration; similarly, records of nominate race from towns in Congo and W Zaire during May-Jun and Oct may relate to migrants, possibly birds which breed in N Angola in Nov and move N for dry season. E African *longipennis* is chiefly a long-distance intratropical migrant, spending non-breeding season from Apr to Oct in equatorial region from S Central African Republic, N & NE Zaire, Uganda and S Kenya S to N Tanzania; regular migrant at L Kivu, in E Zaire, and at Kilima Tea Factory, in S Tanzania, 15 birds ringed during 1982-83 and 40 ringed between third week Apr and early May 1984; some probably migrate up to 2000 km. Migrates at night; frequently attracted to lights. Vagrants recorded N to S Ethiopia and S to SE South Africa.

**Status and Conservation.** Not globally threatened. Locally common to scarce or rare. Not uncommon in parts of Zambia and Zimbabwe; minimum of 6 pairs found in 28 ha of forest in Zambezi Valley, giving density of c. 43 birds/km<sup>2</sup>. In non-breeding range, common at Gedi, in SE Kenya, in Aug 1975, but few records from Kenya and N Tanzania since 1983. True status, however, is difficult to assess owing to this pitta's shyness and skulking behaviour; most reports from E Africa involve nocturnal migrants colliding with windows, but frequency of such reports suggests that it must still be locally common. Status of more sedentary W African populations little known; rare in Sierra Leone and Liberia; uncommon and local in SW Nigeria and Ivory Coast; rare in Ghana; common in Korup National Park, in Cameroon. Habitat destruction and fragmentation could represent a major problem, especially in W Africa. Only rarely seen in the cagebird trade.

**Bibliography.** Alexander (1994), Auber (1964), Baker & Baker (1992), Baker & Howell (1992), Bannerman (1953), Beakbane & Boswell (1984), Bennun & Njoroge (1999), Benson (1940, 1942, 1944), Benson & Benson (1977), Benson & Irwin (1964), Benson & White (1957), Benson *et al.* (1971), Berry & Ansell (1978), Black (1970), Borrow & Deme (2001), Bradley (1994), Britton & Rathbun (1978), Brown (1970), Burke (1969), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1965), Clancey & Maclean (1980), Colston & Curry-Lindahl (1986), Dean (2000), Deme (2001a, 2001b), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood (1977), Elgood *et al.* (1994), Fanshawe (1994), Fishpool & Evans (2001), Forbes-Watson (1972), Friedmann (1978), Gartshore *et al.* (1995), Gatter (1997), Gerhart (1970), Germain & Cornet (1994), Ginn *et al.* (1989),

## 18. Green-breasted Pitta

### *Pitta reichenowi*

**French:** Brève à poitrine verte **German:** Grünbrustpitta **Spanish:** Pita Pechiverde

**Taxonomy.** *Pitta reichenowi* Madarász, 1901, Middle Congo River, above Stanley Pool, Zaire.

Forms a superspecies with *P. angolensis*, and has been considered conspecific on basis of apparent intermediate birds from Cameroon and S Congo; doubts have been expressed, however, over identification of such birds (which could possibly have been nominate race of that species), and there seems little evidence of intergradation where the ranges of the two species approach each other. Monotypic.

**Distribution.** W & S Cameroon to N Gabon, and SW Central African Republic, W, SC & NE Zaire and SW Uganda (Budongo Forest S to Kabale and E to Jinja).

**Descriptive notes.** 17-19 cm. Has black head, broad golden-buff supercilium, rear supercilial feathers paler and erectile; upperparts deep green, rump and tail-coverts sky-blue, tail black; wing-coverts black with violet wash and tipped sky-blue, lesser coverts with much broader blue tips; flight-feathers blackish, tips paler, white patch on primaries; throat white, small black patch on lower throat, breast dull green with often golden-yellow gloss, belly and undertail-coverts red; iris red-brown; bill black; feet pinkish to greyish-white. Sexes alike. Dusky stripes found both on green and blue upperparts and on green breast of 46% of

24 adults examined (both sexes). Differs from *P. angolensis* mainly in green, not buff, breast, white throat, deeper green upperparts. Juvenile is much duller and browner than adult, buffish supercilium becoming slightly paler (but not white) at rear, duller blue in wing, pink belly and vent, orange bill with black central band. Voice. Short bell-like whistle 0.25-0.5 seconds long, repeated several times at rate of c. 10 per 14 seconds; "brrrt" or "prrrt" noise in flight, probably produced mechanically by wings.

**Habitat.** Old secondary forest with dense undergrowth and thickets apparently favoured, but also found in primary forest, at border of a swampy forest and in old plantations with forest regrowth; recorded in stands of mature ironwood (*Cynometra alexandri*) in Uganda. At 1100-1400 m in Uganda.

**Food and Feeding.** Hairless caterpillars, beetles and beetle larvae, termites (Isoptera), maggots, small millipedes (Diplopoda), small centipedes (Chilopoda), an orthopteran, a pillbug (Isopoda) and small snails found in stomachs. Foraging behaviour not documented.

**Breeding.** Eggs in May and Sept and fledglings in Jun and Nov in Cameroon, eggs in Gabon in Jan and in Uganda in May, and fledglings in May and birds with enlarged gonads in Oct-Nov in Zaire; probably breeds in most months. Nest fairly large, domed, with wide side entrance, built from a few large twigs and tough dead creeper stems interwoven with large mass of dead and skeletonized leaves, base a thick pad of rootlets, interior thickly lined with leaves, and placed 1.5-2.5 m up on more or less horizontal trunk or branch of tree, once in crown branches of fallen trunk. Clutch 2-3 eggs, creamy white with dark brown, red-brown and grey spots and blotches with grey-lilac underlying spots, most at larger end, c. 27 × 22 mm; a male captured while incubating, suggesting that both sexes incubate.

**Movements.** Probably sedentary.

**Status and Conservation.** Not globally threatened. Very shy species, rarely seen; most reports concern individuals trapped by local people. In Cameroon, only three reports in period of three years in W (Mt Kupe), but more frequent in S. Locally common in Gabon and parts of Zaire in 1953, but present status there not known. Uncommon in Uganda. Provenance of specimen of a fledgling said to have been collected in Jul 1901 in SE Nigeria (Oguta), i.e. outside species' known range, requires confirmation. Probably overlooked as a result of its skulking behaviour; may be more widely distributed than currently realized. No known threats.

**Bibliography.** Bannerman (1936, 1953), Bates & Ogilvie-Grant (1911), Borrow & Deme (2001), Bowden (2001), Britton (1980), Brown & Britton (1980), Byaruhanga *et al.* (2001), Chapin (1953), Christy (1908), Collar & Stuart (1985), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Lippens & Wille (1976), Lloyd (1999), Louette (1981), Mackworth-Præd & Grant (1957, 1970), Pederson (2000), Prigogine (1984b), Schouteden (1954), Sharpe (1903), Short *et al.* (1990), Stattersfield & Capper (2000), Stevenson & Fanshawe (2001), White (1961), Williams (1963).

## 19. Azure-breasted Pitta

### *Pitta steerii*

**French:** Brève de Steere **German:** Azurbrustpitta **Spanish:** Pita de Mindanao  
**Other common names:** Steere's Pitta

**Taxonomy.** *Brachyurus Steerii* Sharpe, 1876, Dumalon, Mindanao, Philippine Islands.

Has sometimes been considered closest to *P. superba* and *P. maxima*, or to form a superspecies with those and *P. sordida*, but morphological differences appear to be too great for this treatment to be acceptable; probably closest to last of those three. Race *coelestis* poorly differentiated, possibly not meriting taxonomic recognition. Two subspecies recognized.

#### Subspecies and Distribution.

*P. s. coelestis* Parkes, 1971 - C Philippines (Samar, Leyte, Bohol).

*P. s. steerii* (Sharpe, 1876) - Mindanao.

**Descriptive notes.** 19 cm; male 86-100 g, female 69-113 g. Adult has black head, dark green upperparts, green-blue uppertail-coverts, black tail; wings black, secondaries broadly edged greenish, wing-coverts conspicuously silvery greenish-blue; throat white, breast and sides azure-blue, centre of belly black, lower underparts scarlet; iris dark brown; bill black; feet light brown to flesh-coloured, joints pinkish. Sexes alike. Dusky stripes found both on green and blue upperparts and on azure underparts of 46% of 24 adults examined (both sexes). Juvenile is duller than adult, throat mottled, fewer blue feathers in wing, olive-green

upper breast, buffish below, orange tip and base of bill. Race *coelestis* differs only in having blue colours somewhat paler, less green-tinted. **Voice.** Five or more loud, explosive short "whirr", "kwo" or "kva" whistles in series c. 1-5 seconds long, repeated at intervals of 4-5 seconds; also loud "kwéiôô" repeated at 2-5-second intervals reported from Bohol.

**Habitat.** Forest with thick undergrowth, preferring limestone areas; also degraded forest on Mindanao. To 1000 m; to 600 m on Samar, and at 350-750 m on Bohol.

**Food and Feeding.** Insects and worms recorded. Forages on ground, fallen logs and boulders; flicks over dead leaves with bill.

**Breeding.** Almost unknown. Male with enlarged gonads in May and fully fledged juveniles in Jun on Samar, juvenile in Jul on Bohol, and immatures in Sept/Oct on Mindanao; calling heard mostly in Apr-Jun wet season, the period when most Philippine passerines breed. Nest and eggs undescribed. **Movements.** Sedentary.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Rare; recorded from only three localities since 1980. Rare and local on Mindanao, where recent records only from Bislig on E coast and Zamboanga Peninsula in extreme W; possibly still present in Mount Hilong-Hilong Watershed Reserve in N, from where recorded before 1970; was probably widespread on the island in the past. On Bohol, reported regularly in recent years from Rajah Sikatuna National Park (9023 ha). Not reported from Leyte and Samar since 1964 and 1969, respectively. Large-scale destruction of lowland forest has occurred throughout its range, and is continuing. Most forest has now gone on Mindanao, and remaining forest cover at Bislig is being cleared and replanted with exotic trees for commercial production of paper. Almost all suitable forest has disappeared on Bohol, and even in the protected area of Rajah Sikatuna there are problems with illegal tree-cutting for firewood, fires, agricultural expansion and soil erosion. Very little forest remains on Samar and Leyte. Research and fieldwork are needed to determine the species' current status and distribution, and its ecological requirements; the significance of its apparent preference for limestone areas is not fully understood. Effective protection of Rajah Sikatuna is essential, as also is the identification and protection of other possible key sites. No reports of this species being captured for food consumption or the cagebird trade.

**Bibliography.** Anon. (1997a), Brooks *et al.* (1996), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Delacour & Mayr (1946), Dickinson, Dekker *et al.* (2000), Dickinson, Kennedy & Parkes (1991), Hachisuka (1934), Hornskov (1996), Johnson & Stattersfield (1990), Kennedy *et al.* (2000), Lambert (1993), McGregor (1909-1910), Parkes (1971, 1973), duPont (1971), Rand & Rabor (1960), Redman (1993), Stattersfield & Capper (2000), Strange (2000), Whitehead (1899).

## 20. Hooded Pitta

### *Pitta sordida*

**French:** Brève à capuchon **German:** Kappenpitta **Spanish:** Pita Encapuchada  
**Other common names:** Green-breasted(!)/Black-headed Pitta

**Taxonomy.** *Turdus sordidus* Statius Muller, 1776, Philippine Islands.

Recently treated as forming a superspecies with *P. superba* and *P. maxima*, sometimes also including *P. steerii*, but morphological differences seem too great for this treatment; probably closest to last of those three. The four New Guinea races *novaeguineae*, from which described race *hebetior* (from Karkar I, off N Papuan coast) considered indistinguishable, *mefoorana*, *rosenbergii* and *goodfellowi* are geographically isolated from others and show several plumage differences from them; may represent a separate species. Race *palawanensis* possibly better treated as synonymous with nominate. In original description, race *mulleri* was written thus (without umlaut), so this is correct spelling rather than *muelleri*. Twelve subspecies recognized.

#### **Subspecies and Distribution.**

*P. s. cucullata* Hartlaub, 1843 - Himalayan foothills from N India E to N Myanmar, S China (S Yunnan) and N Vietnam (W Tonkin), S to N Bangladesh, Thailand, S Laos and Cambodia; migrates S as far as Sumatra and Java.

*P. s. abboti* Richmond, 1902 - Nicobar Is.

*P. s. mulleri* Bonaparte, 1850 - extreme S Thailand, N Peninsular Malaysia, Sumatra, W Java, Borneo, and W Sulu Is (Sibutu).

*P. s. bangkana* Schlegel, 1863 - Bangka I and Belitung I.

*P. s. sordida* (Statius Muller, 1776) - Philippine Is (except Catanduanes, Masbate, Panay, and Palawan group), including Basilan and Sulu Is (Jolo, Tawitawi).

*P. s. palawanensis* Parkes, 1960 - W Philippines (Calauti, Busuanga, Culion, Palawan, Balabac).

*P. s. sanghirana* Schlegel, 1866 - Sangihe I.

*P. s. forsteni* Bonaparte, 1850 - N Sulawesi.

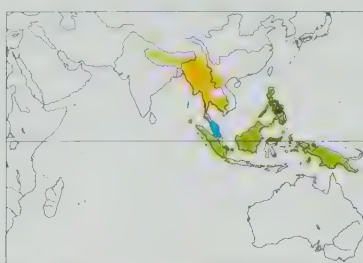

*P. s. novaeguineae* S. Müller & Schlegel, 1845 - New Guinea, including W Papuan Is.

*P. s. mefoorana* Schlegel, 1874 - Numfor I, in Geelvink Bay.

*P. s. rosenbergii* Schlegel, 1871 - Biak I, in Geelvink Bay.

*P. s. goodfellowi* C. M. N. White, 1937 - Aru Is, off S New Guinea.

**Descriptive notes.** 16-19 cm; 42-72 g. Adult of nominate race has entire head, including chin and throat, black, upperparts dark green, uppertail-coverts and large patch on wing-coverts turquoise-blue; flight-feathers black, secondaries edged green, variable white patch on primaries; tail black, tipped blue-green; breast and flanks blue-green, occasionally stronger blue, large black central belly patch, lower belly and undertail-coverts red; iris dark brown; bill black; feet pale brown to pinkish with silver-violet tinge to grey-blue. Female is sometimes slightly duller. Dusky stripes found on both green and blue upperparts and green underparts of 40% of 439 adults examined (both sexes, all races). Juvenile is duller than adult, red-brown forehead, dull greenish above, conspicuous white wing-covert band, white throat, buffy-orange breast becoming buff below, orange tip and base of bill, greyish-pink feet. Races differ mainly in general darkness of plumage, crown colour and amount of white in wing: *palawanensis* is very like nominate but a shade darker, juvenile darker brown below; *cucullata* is large, long-winged, has forehead to nape red-brown,

plumage rather pale in general, less black on belly; *abboti* resembles last but darker, more olive above, bluer below, less white in wing, smaller blue rump and wing patches; *bangkana* has variable amount of dark brown on crown; *mulleri* has entirely black head, black on belly reduced or absent; *sanghirana* differs from previous in more bluish tinge on breast, more black on belly, longer legs; *forsteni* is larger than previous, with longer wings and contour feathers, green tail, no white in wing; *novaeguineae* is darker, dark green above, little or no blue on rump, green tail, golden yellow-green breast, blue-green sides, black belly

patch, dark blue lower flanks, only little white in wing; *goodfellowi* is slightly smaller and darker than last; *rosenbergii* resembles last but more blue on rump, tail black, much darker below, breast washed dark blue without glittering breastband, more extensive dark ultramarine-blue on flanks, red lower breast to vent, no black on belly; *mefoorana* differs from previous in having glossy silver-blue upper breast, black belly patch. **Voice.** Call somewhat variable geographically: in much of range double-noted fluty whistle, "whew-whew" or similar, in Sundas often followed by shorter "whi" or "fi", repeated c. 3-second intervals often for several minutes, but in Borneo more as "quack-quack" repeated 4-35 times; on Nicobars (*abboti*) sharp monotone whistle of three or, rarely, four notes, similar to yelp of small puppy; in Philippines (*sordida*) "waup waup" c. 1 second long, but in Palawan (*palawanensis*) described as more fluty and disyllabic "hweew-hweew"; in New Guinea (*novaeguineae*) loud "wu-wi-wu-wi" with first note falling, second rising, or "kuhwhi-kuwee" with higher second note; much coarser-sounding call on Biak (*rosenbergii*); alarm a squeaky "skyew", in New Guinea "kiaw" sometimes followed by 1-2 low short rasps.

**Habitat.** Wide range of habitats occupied: all types of forest, especially primary riverine forest, secondary forest with heavy understorey or scrub, wet or dry forest, also peat-swamp-forest, dense bamboo jungle, overgrown rubber or coffee plantations, various other commercial plantations (e.g. coconut, nutmeg, *Albizia*), orchards and old gardens, forest clearings with mustard or rice cultivations, forest patches on broken grassland, even mangroves and sago swamps. Occasionally in unusually open habitats on migration. To c. 2000 m in India; mostly in lowlands in SE Asia, but to 915 m on migration; to 500 m in Sumatra, 650 m in Sulawesi and 1000 m in the Philippines; found at up to c. 500 m in New Guinea, locally to 1200 m.

**Food and Feeding.** Insects of many kinds, e.g. beetles, ants, termites (Isoptera), Orthoptera, cockroaches (Blattodea), bugs (Hemiptera), various larvae; also earthworms and snails, and once a leaf found in a stomach. Forages on forest floor among dead leaves, often two birds feeding 5-30 m apart; probes among litter, flicks and scrapes aside leaves. In India, seen to leap into air to catch alate termites.

**Breeding.** Eggs in Apr-Aug in India; in May-Oct in SE Asia, Dec-Apr in Borneo, Feb-Jun in Sulawesi and Dec-Jun in New Guinea; few records from Philippines suggest season May-Jun, but on Tawitawi (Sulu Is) a clutch found in third week Jul. Nest, built by both sexes, a football-sized flattened dome made of twigs, dead and skeletonized leaves, plant fibres, rootlets and moss, lined with finer material, often with a short "walkway" of twigs leading up to side entrance, placed on forest floor. Clutch 2-5 eggs, usually 3-4, white with brown and underlying greyish spots, average c. 27 × 21 mm (*cucullata*); both sexes incubate, period 15-16 days; both also feed and tend chicks, male perhaps taking greater share of duties; young fledge at c. 16 days, and in captivity were able to feed themselves c. 12 days later. Two individuals were recaptured 30 and 38 months respectively after they had been ringed.

**Movements.** Sedentary in most of range. Race *cucullata* mostly migratory, N populations making long-distance post-breeding migration to Peninsular Malaysia and Sumatra, while some possibly cross from mainland to Borneo; S movement mid-Oct to Dec, return in Apr-May; passage nocturnal, 1264 individuals trapped at Fraser's Hill (C Peninsular Malaysia) during 1965-1973. Race *mulleri* may also undertake some long movements in Sumatra and Borneo. In Philippines, nominate race apparently at least a partial short-distance migrant; 1264 individuals ringed at night at Dalton Pass (N Luzon) during 5-year period. Some nomadic movements in seasonally dry regions of New Guinea, from where birds apparently migrate to areas with moister ground that provides suitable foraging conditions.

**Status and Conservation.** Not globally threatened. Common and widespread to rare and local; within its wide distribution is perhaps the most common pitta species where suitable habitat remains. In NW of range locally common, but rare in India; relatively common in Nicobar Is. Rare in China (Yunnan), but fairly common to locally common in SE Asia; c. 10 pairs/km<sup>2</sup> estimated in patches of secondary forest in S Thailand; probably 13-14 pairs/km<sup>2</sup> in parts of non-breeding range in Peninsular Malaysia, and migrants also occur in Bukit Timah Nature Reserve, in Singapore. Rare in Sumatra and Java, but relatively common in Borneo. Uncommon to scarce and local in Sulawesi, but occurs in Lore Lindu and Dumoga-Bone National Parks and in Tangkoko-Dua Saudara Nature Reserve; common on Sangihe I. In Philippines, fairly common to common in some places (e.g. N Luzon and Siquijor) but rare and local in others (e.g. Leyte); occurs in St Paul Subterranean River National Park, on Palawan. Common and widespread in New Guinea and its islands; estimated 6 pairs/10 ha in lowland rainforest near R Brown (S Papua New Guinea). Occurs in several protected areas in addition to those mentioned. Has presumably declined or disappeared in areas where forest and other suitable habitat has been destroyed, but appears tolerant of degraded areas in many parts of range (e.g. N Philippines). This is one of the most frequently seen members of the Pittidae in the cagebird trade; has frequently been bred in captivity.

## 21. Whiskered Pitta

### *Pitta kochi*

**French:** Brève de Koch      **German:** Wangenstreifpitta      **Spanish:** Pita de Luzón  
**Other common names:** Koch's Pitta

**Taxonomy.** *Pitta Kochi* Brüggemann, 1876, Luzon, Philippine Islands.

Closely related to *P. erythrogaster*. Monotypic.

**Distribution.** Luzon, in N Philippines.

**Descriptive notes.** 22-23 cm; one female (fat) 116 g. Male has top of head dark brown, becoming rust-orange on hindcrown and nape; broad pale ash-brown malar stripe (whisker) extending to neck side; upperparts dull dark olive-green, rump and wing-coverts grey-blue, tail dull blue; small white patch on primaries visible in flight; throat and upper breast dark brown, broad blue breastband (often some green at sides), rest of underparts scarlet; iris dark brown to brick-red; bill black; feet brownish to slate-blue. Female differs from male in having fewer grey-blue wing-coverts, often paler red on underparts. Juvenile is mostly dark brown with whitish whiskers, paler below with whitish drop-like spots, pale yellow tip of bill and base of lower mandible. **VOICE.** Monotonous series 2-3 seconds long of 2-9 (usually 5) deep, mournful notes, "haaaawwwww haaww haaww haaww haaww-r" or "gooww-gooww-gooww-gooww", first note longest, following ones slightly accelerating and lower, final note slightly slurred, series repeated at intervals of 7-8 or more seconds, not unlike call of Amethyst Brown-dove (*Phapitreron amethystina*) but longer; also single-note alarm.

**Habitat.** Montane and submontane forest, preferably dominated by oak (*Quercus*) and with closed canopy, often on steep slopes, and with usually dense undergrowth; in higher-elevation mossy forest, rhododendron (*Rhododendron*) and ferns often common in understorey. Locally, e.g. at Mt Diplayag, also evergreen forest with open understorey on lower slopes. Tolerates selectively logged forest and degraded forest; has been observed in heavily degraded secondary forest with dense understorey and bamboo patches (Mt Hamut). Often inhabits areas where wild pigs (*Sus barbatus*) also present. Recorded at 300-2350 m, mostly above 1000 m; highest densities at 900-1500 m.

**Food and Feeding.** Only recorded food small beetles. Forages on ground; flicks aside dead leaves with the bill, digs into soil, sometimes watching or listening with head cocked on one side. Seems to prefer moist ground. Often associated with areas where foraging wild pigs have dug into soil, possibly taking advantage of exposed earthworms and other potential food items.

**Breeding.** Virtually unknown. Calls heard only end Feb-Jun (mostly Apr and Jun), food-carrying adult seen in Apr, and juveniles in Feb, Apr and May; discovery of immatures in late Jan, however, suggests possibly longer season, e.g. to Oct. Reported by local people to nest on ground or to 1 m up in bush, with eggs laid from early Feb.

**Movements.** Some possible movement, but not fully understood; migration or post-breeding dispersal suggested by records of birds trapped at migration watchpoint at Dalton Pass in Jan-Feb, and winter records from S Luzon.

**Status and Conservation.** **VULNERABLE.** **CITES I.** Restricted-range species; present in Luzon EBA. Strongholds are in mountains of Cordillera Central and Sierra Madre, in N of the island, and at Mt Isarog, in SE; a number of records from c. 15 localities since 1990. Occurs in several protected areas: Mount Data and Mount Pulog National Parks, in Cordillera Central, Northern Sierra Madre Natural Park and Maria Aurora Memorial National Park, in Sierra Madre, and Mount Isarog National Park. Other recent records from Mt Adams Peak, Mt Cagua, Mt Polis, Sabian, Balian, and the Angat Watershed (N of Manila). Latest surveys reveal that it is locally common in N Sierra Madre, e.g. at least 20 birds calling on Los Dos Cuernos in 1991 and up to 13 heard in one day on Mt Cetaceo. Uncommon to rare elsewhere, and everywhere local. Presumed to be declining, primarily as a result of extensive habitat loss. Despite the fact that 200,000 ha of Sierra Madre have been declared a Wilderness Area, supposedly to denote a protected World Heritage Site, logging and burning are continuing at an alarming rate, as in most parts of the Philippines; moreover, mossy forests in Cordillera Central are rapidly being converted to agricultural land; several important sites for this pitta are at serious risk of becoming unsuitable. In addition, poor local inhabitants use snares to trap terrestrial birds, both for food and for the cagebird market, putting further pressure on this species. Research is needed to determine its total distribution, precise ecological requirements, and the extent of any migratory movements, in order to plan necessary conservation strategies; and effective and full protection of all sites where it is known to occur.

**Bibliography.** Anon. (1989b, 1989c, 1994, 1997a), Buensuceso (1985), Collar & Andrew (1988), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Crosby (1997), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson, Dekker *et al.* (2000), Dickinson, Kennedy & Parkes (1991), Gonzales & Rees (1988), Goodman & Gonzales (1989, 1990), Hachisuka (1934), Jakobsen & Andersen (1996), Jensen (1991), Kennedy *et al.* (2000), McClure & Leelavit (1972), McGregor (1909-1910, 1920), Mitchell & Redman (1994), Morris (1997), Pitches (1997b), duPont (1971), Poulsen (1995), Stattersfield & Capper (2000), Strange (2000), Whitehead (1899).

## 22. Red-bellied Pitta

### *Pitta erythrogaster*

**French:** Brève à ventre rouge      **German:** Blaubrustpitta      **Spanish:** Pita Ventrirroja  
**Other common names:** Blue-breasted/Red-breasted Pitta; Macklot's Pitta (*macklotii*); Sula Pitta (*dohertyi*)

**Taxonomy.** *Pitta erythrogaster* Temminck, 1823, Manila, Luzon, Philippine Islands.

Closely related to *P. kochi*. Wide geographical variation in plumage, with some indication that coloration varies clinally, and also in voice. Distinctive race *dohertyi* sometimes treated as a separate species, mainly because it shows notable plumage differences and possibly differs vocally, but other intraspecific plumage variation is considerable, and claimed vocal differences remain uncertain; future research and DNA analysis may reveal that some other races, e.g. *inspeculata*, *novaehibernicae*, *rubrinucha* and *splendida*, should also be elevated to species rank; New Guinea taxa have sometimes been treated as separate species, *P. macklotii*. Other described forms include *thompsoni* (Calauit and Culion, in W Philippines), regarded as synonymous with highly variable nominate race; *obiensis* (Obi I, S of Halmahera), which is indistinguishable from *rufiventris*; and

*kuehni* (Kai Is) and *digglesi* (N Queensland, Australia), appearing to show no constant differences from *macklotii*, although Australian birds considered by some authors to be brighter and paler. Race *habenichti* perhaps also better merged with last. Twenty-three subspecies recognized.

#### Subspecies and Distribution.

*P. e. erythrogaster* Temminck, 1823 - Philippine Is (except Palawan group).  
*P. e. propinqua* (Sharpe, 1877) - Palawan and Balabac.  
*P. e. caeruleitorques* Salvadori, 1876 - Sangihe I.  
*P. e. inspeculata* A. B. Meyer & Wiglesworth, 1894 - Talaud Is.  
*P. e. paliceps* Brüggemann, 1876 - islands of Siao and Tahulandang, N of Sulawesi.  
*P. e. celebensis* S. Müller & Schlegel, 1845 - Sulawesi, including Manterawu and Togian Is.  
*P. e. dohertyi* Rothschild, 1898 - Banggai Archipelago and Sula Is, E of Sulawesi.  
*P. e. rufiventris* (Heine, 1859) - N Moluccas (Morotai, Halmahera, Moti, Bacan, Mandioli, Damar, Obi, probably also Kasiruta).  
*P. e. cyanonota* G. R. Gray, 1860 - Ternate, off W Halmahera.  
*P. e. bernsteini* Junge, 1958 - Gebe I (between Halmahera and Waigeo I).  
*P. e. rubrinucha* Wallace, 1862 - Buru, in S Moluccas.  
*P. e. piroensis* Muir & Kershaw, 1910 - Seram.  
*P. e. macklotii* Temminck, 1834 - W & S New Guinea, including W Papuan Is (Waigeo, Batanta, Salawati, Misoöl) and Yapen I in Geelvink Bay, and NE Australia (N & E Cape York Peninsula).  
*P. e. habenichti* Finsch, 1912 - N New Guinea (Weyland Mts E to Astrolabe Bay).  
*P. e. aruensis* Rothschild & Hartert, 1901 - Aru Is.  
*P. e. obliata* Rothschild & Hartert, 1912 - mountains of upper R Aroa, in SE New Guinea.  
*P. e. lorae* Salvadori, 1890 - extreme SE New Guinea (E from R Kumusi and Cloudy Bay).  
*P. e. extima* Mayr, 1955 - New Hanover, in Bismarck Archipelago.  
*P. e. novaehibernicae* E. P. Ramsay, 1878 - New Ireland.  
*P. e. splendida* Mayr, 1955 - Tabar I (E of New Ireland).  
*P. e. gazellae* Neumann, 1908 - S Bismarck Archipelago (Umboi, New Britain, Tolokiwa, Lolobau, Watom and Duke of York).  
*P. e. finschii* E. P. Ramsay, 1884 - D'Entrecasteaux Archipelago (Fergusson I, Goodenough I).  
*P. e. meeki* Rothschild, 1898 - Louisiade Archipelago (Rossel I).

**Descriptive notes.** 16-18 cm; male 50-65 g, female 46-70 g. Adult of nominate race has crown, nape and neck side deep red-brown, lores and supercilium dark brown, cheeks cinnamon; upper mantle blue, lower mantle and back dark green (variable), rump and tail blue; upperwing-coverts mostly deep blue; flight-feathers black, variably edged blue, inner secondaries mostly blue, variable small white spots on primaries; upper throat brownish, lower throat and upper breast black, sometimes with white throatband, a broad glossy blue band across breast becoming green at sides (variable), rest of underparts scarlet; iris dark

brown to reddish-brown, pale olive or bluish-slate; bill black; feet dark brown with lilac tinge to greyish-blue or pinkish-slate. Female is duller, more green and less blue on breast, red of underparts a shade paler. Small dusky stripes found on upperparts and blue breastband of 24% of 585 adults examined (both sexes, all races). Juvenile is dull brown above, rump and tail tip dull blue, paler below, throat whitish, breast with dark brown and off-white spots, bill dark horn, tip and base of lower mandible paler. Races vary considerably in plumage details: *propinqua* is very like nominate, but on average brighter and slightly smaller; *caeruleitorques* has top of head more uniformly brownish-red, brighter on nape, black band between blue breast and red belly; *celebensis* has variably sized blue stripe from midcrown to nape, more blue on breast with broad black band below; *paliceps* resembles last but paler, crown with less blue, little or no black on breast; *inspeculata* is distinctive, entire head dark chestnut-brown, upperparts all blue, breastband dark blue and narrow, iris grey-brown; *dohertyi* is also distinctive, with entire head, neck and throat black except for chestnut crown (variable), glossy green upperparts, also narrow light blue breastband with broad blackish band below, female with white iris; *rufiventris* has brighter reddish nape, dull dark green to dull blue rump, no blue on mantle, pale throat, more extensive blue on breast with thin black and greenish band below; *cyanonota* has nape bright rufous, upperparts dull blue, cheeks and throat pale buffy-brown, entire breast pale blue, sometimes thin black line below breast; *bernsteini* is marginally bigger than previous, slightly paler above, blue of breast silvery; *rubrinucha* has pale blue on rear crown centre and behind eye, small contrasting red area on nape, no blue on mantle; *piroensis* resembles previous, but darker green above, larger red nape patch; *macklotii* has forecrown, face and throat dark, hindcrown and nape bright orange-rufous, ear-coverts and a stripe over eye tinged blue, no blue on mantle, black lower breastband of extremely variable depth; *habenichti* is very like last, but nape brighter red or orange-red; *aruensis* resembles previous two but smaller, occasionally some blue on mantle; *lorae* has darker head and nape, sometimes narrow blue line on upper mantle, bill larger; *obliata* has nape pale yellow-brown, perhaps bluer (less green) upperparts; *novaehibernicae* has walnut-brown crown, contrasting reddish-orange nape, bluish ear-coverts, no black on throat or breast; *extima* is larger than last, with some blue feathers on midcrown, more bluish-green back; *gazellae* differs from last in usually stronger blue line on midcrown, redder crown side; *splendida* has nape scarlet, thin blackish hindcrown, upperparts deep blue, breast side blue; *meeki* is duller, throat more greyish, broad black lower breastband finely tipped red; *finschii* has crown to nape uniform dull dark chestnut, upperparts deep blue, female paler brown on chin and throat. **VOICE.** Varies geographically: in Philippines "waaaaauup aaaaawwwwww", first note vibrating and rising, second falling, c. 3 seconds long, repeated at intervals of 10-12 seconds; in New Guinea region "crooooooi-crooooouw" or "karaa-karaa" c. 4-5 seconds long, second note sometimes repeated once or, occasionally, twice; in N Australia a rasping "quor-eye-quor-or", last two notes drawn out, or harsh "kraa-kraa", on Sangihe, however, a more stuttering series of notes; in Sulawesi call shorter, 2-1 seconds, and hoarser, with second note longer than first and sometimes rising at beginning or end, also drawn-out mournful "oppo" between partners; on Obi a quite different "foh-foh"; race *dohertyi* (Banggai and Sula Is) thought to utter trisyllabic phrase followed by very brief pause and then descending series of five drawn-out notes that decrease in volume.

**Habitat.** Found in many habitats, from dense primary rainforest to logged or heavily degraded forest and scrub, plantations, remnant forest patches within cultivations, bamboo groves, and thickets near rivers. Often found in forest on volcanic soils in Sulawesi. Mostly in lowlands below 1200 m; to at least 1400 m in SC Philippines (on Negros), and recorded to c. 1800 m in New Guinea and to 2100 m in N Moluccas (Bacan).

**Food and Feeding.** Stomach contents included insects and their larvae, e.g. small beetles, also snails, earthworms, and even green plant material and maize (*Zea mays*) seeds. Foraging behaviour poorly known; feeds mostly on forest floor, mainly by gleaning, possibly also with some digging as not infrequently seen with dirt on bill. Reported as hopping on ground, now and then pausing to

inspect dead leaves, then again hopping, following irregular course, and occasionally flying up to c. 5 m between feeding sites. Possibly uses "anvils" to break snail shells.

**Breeding.** Over wide range breeding recorded in nearly all months: Nov-Sept in Philippines; singing males on territory in Jan-Mar, season probably to Oct, in Sulawesi; probably in most months in Moluccas, and nests with eggs in Nov (Buru); Mar-Jun in W & N New Guinea and probably mostly Apr-Oct in S & E; mostly during Dec-Apr rains in Bismarck Archipelago; Jan-Feb in Australia. Domed nest c. 17-22 cm in diameter, with side entrance c. 5-6 cm across, built of twigs and leaves, some skeletonized, grass and ferns, held together with cotton or hairy plant materials, most often placed on ground or low in scrub or tree, rarely to 10 m above ground. Clutch normally 2 eggs, occasionally 3 or 4 (but usually 3 in Australia), creamy white, spotted and blotched brownish to purplish-brown with grey-lilac underlying spots, average size in Philippines (*erythrogaster*) 27 × 20 cm; both sexes incubate, female probably taking greater share of duties; incubation and fledging periods not documented.

**Movements.** Sedentary over much of range. Some short local movement in Philippines: in five-year study at Dalton Pass (N Luzon), c. 2000 individuals trapped at night during Sept-Dec, of which nine recaptured at same site within 2 months and one caught 3 years later at locality 48 km to NW; also, individuals sometimes captured on boats up to 6 km offshore, e.g. off Luzon and Leyte. Possibly some nomadic movements in New Guinea and Wallacea, perhaps when forest floor is so dry that it makes foraging difficult. Apparently migratory in NE Australia, where generally absent May-Dec, although a few possibly resident; believed to migrate N to S New Guinea as recorded on islands in Torres Strait, but few data.

**Status and Conservation.** Not globally threatened. Race *dohertyi* currently considered Near-threatened. Fairly common locally in Philippines, but rare on Mindoro, Palawan, Negros and Leyte; rare in Rajah Sikatuna National Park, on Bohol. Locally common in Sulawesi, where occurs in Lore Lindu and Dumoga-Bone National Parks and in Tangkoko-Dua Saudara Nature Reserve. Recorded in low densities on Halmahera, but common and widespread on Bacan, Obi and Buru; very rare on Seram, where present in Manusela National Park. Little information on

New Guinea populations, but probably common in many areas; density of c. 30 birds/km<sup>2</sup> estimated at one study site in SE. Locally common in NE Australia. On the Banggai and Sula Is, race *dohertyi* (recently treated by some authors as a full species) is an uncommon and local inhabitant of lowland evergreen forest below 200 m; this habitat, which has already suffered serious alteration, is subject to increasing levels of clearance, degradation and disturbance; although this taxon tolerates secondary habitats, it is thought to be declining within its small range. The species' conservation status on many small islands is not known, but extensive deforestation which takes place on a good number of these may be a major threat to the pitta's survival. In various parts of its range additional pressure comes from hunting; in N Luzon, for example, many pittas are caught for local consumption or to be sold alive to pet shops.

## 23. Indian Pitta

### *Pitta brachyura*

**French:** Brève du Bengale

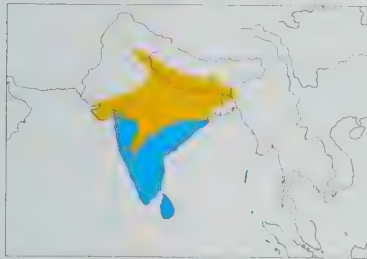

**German:** Bengalenpitta

**Spanish:** Pita India

**Other common names:** Bengal/Blue-winged(!)/Green-winged Pitta

**Taxonomy.** [*Corvus*] *brachyurus* Linnaeus, 1766, Moluccas and Sri Lanka; error = Sri Lanka. Forms a superspecies with *P. nympha*, *P. moluccensis* and *P. megarhyncha*. Formerly treated by many authors as conspecific with first of those, but differs in morphology, plumage and vocalizations. Has also been treated as conspecific with *P. elegans*. Monotypic.

**Distribution.** Breeds in NE Pakistan (Margalla Hills) and in foothills of Himalayas from W Himachal Pradesh (Dharmasala, Kangra) E to Sikkim and Bangladesh (has probably bred), and S to W & C India (S to Gujarat, extreme N Karnataka, E Maharashtra and C Bihar); migrates S to S India and Sri Lanka.

**Descriptive notes.** 18 cm; 47-66 g. Adult has top of head dark buff with black central stripe, white supercilium, broad black band from lores to nape with conspicuous white line beneath eye; upperparts dark green, rump blue, tail black with dull blue tip, large glossy blue patch on lesser wing-coverts; flight-feathers blackish, tipped pale, large white patch on primaries and white tips to inner secondaries; chin and throat whitish, rest of underparts golden buffish except for scarlet belly centre and undertail-coverts; iris dark brown; bill black, feet pinkish. Sexes alike. Dusky stripes found on green and blue upperparts of 54% of 160

adults examined (both sexes). Differs from *P. nympha* in slightly smaller size, head pattern, darker underparts, less extensive red below. Juvenile is duller than adult, little or no pinkish on belly, orange bill with black near tip. **VOICE.** Call a short double whistle, "weeet-pyou", "wee-tiou" and similar, sometimes likened to the words "quite clear", second note descending, the whole occasionally preceded by additional brief note, often accompanied by harsh notes, and repeated 3-4 times in 10 seconds for several minutes in breeding period; more rarely, single "weeew"; also other harsher sounds, e.g. "chee".

**Habitat.** Inhabits deciduous and evergreen forest with dense undergrowth in lowland and foothills, as well as scrub and bamboo jungle or sal (*Shorea*) forest; also found in dried-out riverbeds with grassy banks. Breeds in moist ravines and thick thorny bushes in Pakistan. Non-breeding visitors in Sri Lanka occur in thick forest and secondary jungle, and on initial arrival also often found in gardens or coffee plantations and even town parks. Present up to 1700 m in India, but only up to 1200 m during breeding; at 450-750 m in Pakistan; up to 1800 m, but mostly lower, in Sri Lanka.

**Food and Feeding.** Various insects, such as termites (Isoptera) and ants, insect larvae, also earthworms, small snails, millipedes (Diplopoda); reported to take dipteran maggots from human excrement near villages, and seen to consume larvae of coffee beetle from manure. Young fed on orthopterans, especially mole-cricket (Gryllotalpidae), at one nest. Forages on ground in manner of a thrush (Turdidae), tossing aside leaves, digging with bill in wet soil. Maintains feeding territories in non-breeding areas.

**Breeding.** Breeds in rainy season, May-Aug, rarely Apr and Sept; Jul-Aug in Pakistan. Nest c. 20 × 15 × 15 cm, shaped like a rugby football, with side entrance, built of twigs, bamboo leaves, grass, moss and fibrous roots, often lined with fine leaves, and placed 3-4 m, sometimes to 15 m, above ground in tree, occasionally on ground. Clutch 4-6 eggs, usually 5, glossy china-white with fine red-brown and underlying grey-lilac spots, mostly at broad end, average c. 25 × 21 cm; both parents incubate and both feed chicks: in captivity, incubation period 17 days, fledging period 15 days, young independent 5 days later.

**Movements.** Migratory; spends non-breeding season in peninsular India (mostly S of Maharashtra and Madhya Pradesh) and Sri Lanka. Departure from breeding grounds from Aug, some not leaving until Oct (e.g. in Pakistan), with migrants recorded in Sept-Oct in C India, and reaching Sri Lanka mid-Oct; return starts Apr, arrival in N breeding areas mostly in late May. Migrates at night, in small flocks.

**Status and Conservation.** Not globally threatened. Fairly common to scarce, and local. Population in Pakistan (Margalla Hills) estimated to be 18-20 pairs in 1982. Fairly common but local in India; in N fairly common at Dehra Dun; was formerly common at several places, with large numbers recorded on passage in the peninsula, but obviously declined in 20th century. In Nepal, common summer visitor only in Chitwan National Park; local elsewhere, and rare at Sukla Phanta and Bardia. Rare in Bangladesh; recorded only at Modhupur Forest, where probably bred in 1989, but no other information. Status in NE Indian Subcontinent uncertain; has been said to occur in Arunachal Pradesh, Assam (where villagers claim to have caught migrants in S) and Manipur, but no documented records; further fieldwork required to determine this species' true distribution. Fairly widespread in S India outside breeding season, with non-breeders present in at least four protected areas in Western Ghats; common winter visitor in Sri Lanka, where present in Yala, Bundala and Uda Walawe National Parks and in Sinharaja Forest Reserve. Although this pitta appears to be reasonably tolerant of human disturbance, clearing of forest for agriculture and urban development pose increasing problems in India, with its high human population. Moreover, large numbers of this species are caught while on migration, almost solely for food. The cagebird trade appears to be relatively insignificant; e.g. in 1986 only 70 birds were known to have been traded.

## 24. Fairy Pitta

### *Pitta nympha*

**French:** Brève migratrice

**German:** Nymphenpitta

**Spanish:** Pita Ninfa

**Other common names:** Lesser Blue-winged/Chinese/Swinhoe's Pitta

**Taxonomy.** *Pitta nympha* Temminck and Schlegel, 1850, Korea.

Forms a superspecies with *P. brachyura*, *P. moluccensis* and *P. megarhyncha*. Formerly treated by many authors as conspecific with first of those, but differs in morphology, plumage and vocalizations. Monotypic.

**Distribution.** E & SE China, S Korea, S Japan and Taiwan; migrates S to N Borneo.

**Descriptive notes.** 19 cm; 67-155 g. Adult has top of head chestnut with black median stripe, pale buffish supercilium, broad black band from lores and beneath eye to nape; upperparts dark green, rump pale blue, tail black with green-blue tip; blue lesser upperwing-coverts; flight-feathers black, secondaries edged blue to green, large white primary patch; throat whitish, breast and flank dirty buff with strong green tinge, lower breast, belly and undertail-coverts scarlet; iris dark brown; bill black; feet pale brown-lilac. Sexes alike. Dusky stripes found on green and blue upperparts of 40% of 30 adults examined (both sexes). Differs from

*P. brachyura* in larger size, head pattern, no white beneath eye, paler underparts with red extending farther forward on to breast. Juvenile is much duller, with large white spots on median wing-coverts, bill dark brown with scarlet-orange tip. **VOICE.** Clear whistle, "kwah-he-wwa-wu", similar to that of *P. moluccensis* but longer and slower; "kriaih" or "kahei-kahei" as alarm; in captivity, "zip" or "hyp" often heard.

**Habitat.** In S Korea and Japan prefers moist lowland and foothill forest with thick undergrowth, especially near streams, but occasionally breeds in plantations in Japan; also occurs in scrub jungle and light deciduous forest in China, and found in scarcely populated wooded areas and bamboo groves in Taiwan. Present in lowlands and up to 1200 m, but in Japan mostly below 500 m; up to 1300 m in Taiwan. In non-breeding range, occurs in mixed dipterocarp forest and primary forest, to c. 1100 m.

**Food and Feeding.** Beetles, ants, centipedes (Chilopoda) and snails reported. A pair studied in Taiwan fed nestlings almost solely on earthworms. In captivity, observed to use stone as an "anvil" for smashing snail shells. Foraging behaviour little known; spends much time on ground, where seeks food among leaf litter. Birds on passage sometimes feed in more open areas, showing little fear of humans.

**Breeding.** Season May-Jul in Japan and Taiwan and May-Jun in Korea. Domed nest up to 45 cm wide (in one case only c. 20 cm in diameter) and 40 cm high, with side entrance, constructed mostly of twigs with a few leaves, lined with moss and finer material, sometimes with platform of twigs in front of entrance, placed 2-7.5 m up in fork of tree or in rock cleft. Clutch 4-6 eggs, creamy white with fine purple-brown spots; both parents feed young; incubation and fledging periods not recorded.

**Movements.** Long-distance migrant; non-breeders present in Borneo mid-Oct to Mar. Movements poorly understood; may have two distinct flyways, or take W route in autumn and more direct E route in spring. Most N populations probably move S through China, then across sea to N Borneo; rare passage migrant in Vietnam (E Tonkin, N & C Annam) in both autumn and spring, mainly in Apr; possibly resident in SE China (Guangxi, Guangdong). Japanese population leaves in Aug-Sept, returning in mid-May; some birds from there and from S Korea possibly move only as far as S China, but large numbers recorded in Taiwan in spring during 1980s suggest non-breeding quarters farther S, with possible return route through Philippines (no documented records) and then N c. 1100 km across East China Sea. Biometrics indicate that migrants collected on E China coast (near Shanghai) originated from Korea and Japan, while 8 specimens from Borneo appeared to be from S China.

**Status and Conservation.** **VULNERABLE.** CITES II. Rare; global population probably no more than a few thousand individuals. Protected by law throughout breeding range; occurs in several protected areas, including Keoje Island Natural Monument, in S Korea, and Kirishima-Yaku National Park, in Japan. Rare in Japan, with most birds seen on S Honshu, Shikoku and Kyushu; best-studied site is Mi-ike, in SW Kyushu, where c. 20 birds recorded in most years. Rare and local in S Korea, with fewer than 20 breeding pairs in 1994 on islands off S coast. Uncommon to rare in Taiwan, but estimated 20 pairs in a 70-ha forest around Hubei, in W; formerly more common on the island, and hundreds recorded on migration each year. China has been assumed to be the stronghold of this species, and it was once locally common in S, but appears now to be rare throughout range. Generally reported as rare to occasionally locally common in Bornean non-breeding range, but confusion with commoner *P. moluccensis* cannot be excluded. Large-scale deforestation the main threat, especially in China, where most lowland forest has been cleared and remaining areas are subject to further destruction through uncontrolled fires. Despite legal protection, human disturbance and hunting are additional problems in Taiwan and S Korea, as well as in China, and are thought to have contributed to this pitta's decline. In the past very large numbers were trapped in spring in Taiwan for the cagebird trade, adversely affecting not only the local population but also those farther N; with far fewer pittas now seen there, this practice has largely ceased. The possibility that a great many individuals are ocean-crossing migrants may also contribute to the species' vulnerability. Surveys urgently needed in order to establish its precise current distribution and population size, and to determine any habitat management that could benefit it. Priorities include effective protection of habitats where it is known to occur, and prevention of hunting and other disturbance.

## 25. Blue-winged Pitta

### *Pitta moluccensis*

**French:** Brève à ailes bleues

**German:** Kleine Blauflügelpitta

**Spanish:** Pita Aliazul

**Other common names:** Lesser Blue-winged/Little Blue-winged/Moluccan Pitta

**Taxonomy.** *Turdus Moluccensis* Status Muller, 1776, Moluccas; error = Malacca.

Forms a superspecies with *P. brachyura*, *P. nympha* and *P. megarhyncha*. Sometimes considered conspecific with last, but differs in morphology, plumage pattern and behaviour, separated ecologically, and no apparent interbreeding where ranges come into contact. Has also been treated as conspecific with *P. elegans*. Monotypic.

**Distribution.** Breeds from S & E Myanmar (S to Tenasserim) and S China (S Yunnan) through Thailand (except C and most of E), Laos, Cambodia and Vietnam (Annam, Cochinchina) to N Peninsular Malaysia (Langkawi I, Perlis); migrates to Sumatra and Borneo (possibly breeds).

**Descriptive notes.** 18-20 cm; 54-146 g. Adult has blackish head with broad buffy brown sides of crown and buffy supercilium; upperparts dark green, rump turquoise-blue, tail black with blue-green tip; inner half of wing turquoise-blue, primaries black with broad white band; throat white, rest of underparts cinnamon-buff, with centre of belly to undertail-coverts crimson; iris red-brown to dark brown; bill blackish; feet range from pale brown with lilac tinge to pale fleshy. Sexes alike. Dusky stripes found on green and blue upperparts of 41% of 238 adults examined (both sexes). Differs from *P. megarhyncha* in prominent supercilium, brighter coloration in prominent supercilium, brighter coloration in prominent supercilium, brighter coloration in prominent supercilium.

ours, smaller bill. Juvenile is a duller version of adult, paler crown edged dark brown, no red on belly, bright red base and tip of bill. Voice. Loud clear "taew-laew", second note stressed, usually doubled as "taelaew-taew" or "taew-taew", lasting less than 1 second, repeated every 3-5 seconds; alarm a harsh "skyeew".

**Habitat.** Found in variety of habitats, from moist or dry primary forest with dense or sparse undergrowth to mixed deciduous forest, secondary forest, scrub, bamboo; also mangroves, plantations and even parks and gardens on migration. Lowlands to 800 m; to 1800 m on migration and in non-breeding range.

**Food and Feeding.** Diet includes many kinds of insects, e.g. scarab beetles (Scarabaeidae), grasshoppers (Acrididae), hornets (Vespidae), ants, fireflies or glow-worms (Lampyridae) and coreid bugs, and variety of insect larvae; also takes spiders, earthworms, snails and crustaceans (crabs, shrimps). Uses stones as "anvils" when cracking snail shells. Forages on ground; hops in manner of a thrush (Turdidae).

**Breeding.** Apr-Aug. Nest 15-25 cm in length and 13-20 cm in height and width, sometimes with platform extending c. 10 cm in front of side entrance, a very untidy structure mostly of twigs, leaves (often of bamboo) and roots, lined with fibres, and usually placed on ground, occasionally up to 4 m up in tree or palm. Clutch 3-7 eggs, normally 4-5, whitish to lilac-grey with purple spots and scribbles, average c. 26 × 21 mm; both sexes incubate, period 18 days in captivity; no information on nestling period. Longevity at least 5 years 7 months in the wild.

**Movements.** Migratory; probably resident in extreme S of range in Malay Peninsula, and possibly also in extreme S Myanmar (S Tenasserim). Otherwise a long-distance migrant, with non-breeding quarters in Peninsular Malaysia, Sumatra and its islands and Borneo. Leaves breeding grounds in Sept, peak passage through Peninsular Malaysia second half Oct; return from late Mar, most arriving back in breeding areas from mid-Apr. Vagrants recorded from many areas, e.g. SE China (Hong Kong, Fujian), Philippines (Palawan, Basilan), Sulu Is (Tawitawi), N Sulawesi, and in E Indian Ocean on Christmas I; one vagrant even appeared in C China, in SW Gansu, at an elevation of 2980 m; also, four records from NW Australia, including singles in Nov 1994 and Dec 1995.

**Status and Conservation.** Not globally threatened. Widespread and fairly common to locally common over most of its range; rare in China. Density in patches of secondary forest in peninsular Thailand estimated at c. 10 pairs/km<sup>2</sup> in late 1980s. Status in Borneo unclear; although generally considered only a non-breeding visitor, several records suggest possible breeding, e.g. a female in Sabah at end Dec with well-developed brood patch and slightly enlarged oviduct, and reports of calling throughout year in E & C parts of island; further fieldwork required. Occurs in several protected areas throughout range, e.g. Khao Yai and Kaeng Krachan National Parks, in Thailand, Nam Bai Cat Tien National Park, in Vietnam, and during non-breeding period Taman Negara National Park, in Peninsular Malaysia, and Bukit Timah Nature Reserve, in Singapore. Not dependent on primary forest; fairly tolerant of habitat alteration, and able to survive well in secondary habitats. Hunted for food in some areas (e.g. Thailand), and figures prominently in the cagebird trade. Has been bred in captivity.

**Bibliography.** van Balen & Prentice (1997), Bangs & Van Iyne (1931), Barker & Vestjens (1990), Batchelor (1959), Benson (1970), Bransbury *et al.* (1994), Blunkill & Chasen (1990), Carey *et al.* (2001), Casement (1989), Cheng Isohsin (1987), Coates & Bishop (1997), Deignan (1945), Delacour (1951), Delacour & Jahouille (1940), Dickinson & Dekker (2000), Dickinson, Dekker *et al.* (2000), Dickinson, Kennedy & Parkes (1991), Duckworth *et al.* (1999), Dymond (1994), Eames & Eriksen (1996), Eames & Lambert (1994), Eames & Robson (1992), Ellis (2002), Evans, G.H. ## 26. Mangrove Pitta

### *Pitta megarhyncha*

**French:** Brève des palétuviers

**German:** Große Blauflügelpitta

**Spanish:** Pita de Manglar

**Other common names:** Larger Blue-winged/Malay Pitta

**Taxonomy.** *Pitta megarhyncha* Schlegel, 1863, Bangka, off south-east Sumatra.

Forms a superspecies with *P. brachyura*, *P. nympha* and *P. moluccensis*. Sometimes considered conspecific with last, but differs in morphology, plumage pattern and behaviour, separated ecologically, and no apparent interbreeding where ranges come into contact. Monotypic.

**Distribution.** S. Bangladesh patchily S on coast to W peninsular Thailand, W & E Peninsular Malaysia, E Sumatra, Riau Archipelago and Bangka I.

**Descriptive notes.** 18-21 cm; 92-120 g. Adult has top of head grey-brown, sometimes with indistinct thin black median stripe, broad black band from lores back to nape; upperparts dull dark green, rump glossy violet-blue, tail black with green or blue tip; inner half of wing glossy ultramarine with violet wash, primaries black with large white patch; throat whitish, rest of underparts cinnamon-buff, mid-belly to undertail-coverts scarlet; iris dark brown; bill black; feet dark flesh-coloured. Sexes alike. Dusky stripes found on blue and green wing-coverts on only one of 23 adults examined (both sexes). Differs from *P. moluccensis* in

rather duller plumage, no supercilium or only narrow line behind eye, longer and stronger bill. Juvenile is duller, little or no ultramarine in wing, belly patch pinkish, bill with red gape. Voice. Loud and clear "hhwa-hwa" or "wieuw-wieuw" or "tu-will" c. 1 second long, first note rising, second more even, repeated at intervals of c. 4 seconds, apparently also given loudly from nest; alarm "skyeew" or "keew".

**Habitat.** Coastal mangroves; also recorded from river borders in tidal areas, including inland where mangroves or nipa palms (*Nypa fruticans*) still occur.

**Food and Feeding.** Molluscs, as well as ants and other insects, found in stomachs; diet thought to consist chiefly of crabs, for which the large bill is particularly suitable. Forages on mud around mangrove roots and in adjacent drier areas; at times ventures on to more exposed areas of mud on seaward side, where also seen to perch on moored boats.

**Breeding.** Apr-Aug. Domed nest c. 45 cm in diameter, constructed of sticks, dead leaves, grass and coconut fibres, sometimes with mud over roof, on solid platform of long sticks which extends in front of side entrance; usually placed on ground, once on top of mound made by mud-lobster (Thalassinidae), but not infrequently up to 1.5 m up in dense scrub. Clutch 2-4 eggs, glossy creamy white with tinge of lilac and streaked and mottled red-brown, dull maroon or pale inky purple with underlying grey-lilac markings, average c. 26 × 22 mm; incubation probably by both sexes, period at least 15 days; nestling period not known.

**Movements.** Sedentary.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally scarce to locally common. Rare and very local in Bangladesh, but common at Khulna. Probably locally not uncommon in Myanmar. Uncommon to locally common in Thailand, where Krabi may be best site. In Peninsular Malaysia confined to the few remaining pockets of mangroves on W coast, including in Kuala Selangor National Park, and a couple of sites on E coast (in Pahang and Johor). Occurs at Changi Beach, Pulau Ubin, in Singapore. Locally fairly common in Sumatra, and common at R Metas and R Rawa in 1996. This species' restriction to coastal mangroves suggests that its total population is likely to be small. In addition, this habitat has suffered severely in recent decades and is diminishing at an alarming rate, mainly through clearance for charcoal production and fuelwood, and being replaced by fish and shrimp ponds. This pitta could become threatened in near future. Single old record from Borneo, a specimen purportedly collected in Sarawak in 1891; lack of subsequent records has led to doubts regarding the origins of this specimen.

**Bibliography.** Abdulali (1976), Ali & Ripley (1983), Allen (1955), Anon. (1988c), Bransbury *et al.* (1994), Bucknill & Chasen (1990), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Gibson-Hill (1949), Glenister (1971), Grimmett *et al.* (1998), Harvey (1990), Holmes (1996), Husain & Sarker (1973), Inskipp *et al.* (1996), Jeyarajasingam & Pearson (1999), Kazmierczak (2000), Lambert (1996), Lekagul & Round (1991), Lewis *et al.* (1989b), Lim Kim Seng (1984, 1994), MacKinnon & Phillips (1993), Madoc (1976), van Marle & Voous (1988), McClure & Osman (1968), Medway & Wells (1976), Mees (1971, 1986), Meyer de Schauensee (1958), Noske (1995), Paynter (1970), Rajathurai (1996), Riley (1938), Ripley (1982), Robson (1996b, 1996c, 2000d, 2001), Robson & Komolpalin (1988), Round (1988), Smythies (1986, 1999), Stattersfield & Capper (2000), Strange (2000), Verheugt *et al.* (1993), Wells (1985b, 1990c), Whistler (1934), White & Bruce (1986), Whitehouse (1988).

## 27. Elegant Pitta

### *Pitta elegans*

**French:** Brève élégante

**German:** Schmuckpitta

**Spanish:** Pita Elegante

**Other common names:** Two-striped Pitta (*vigorsii*)

**Taxonomy.** *Pitta elegans* Temminck, 1836, Timor.

Often considered conspecific with *P. brachyura* or *P. moluccensis*. Has also been treated as a subspecies group of *P. versicolor*, but possibly best regarded as forming a superspecies with that together with *P. anerythra* and *P. iris*. Race *vigorsii* sometimes given full species rank because of its mosaic distribution, but such treatment seems unwarranted. Described forms *kalaonensis* (Kalao, S of Sulawesi) and *plesseni* (Kalaotoa) considered indistinguishable from *virginalis*, while *hutzi* (S Nusa Penida I, in Lombok Strait) and *everetti* (Alor) appear inseparable from *concinna*. Five subspecies recognized.

**Subspecies and Distribution.**

*P. e. concinna* Gould, 1857 - Lesser Sundas, on Nusa Penida, Lombok, Sumbawa, Flores, Adonara, Lomblen and Alor.

*P. e. maria* Hartert, 1896 - Sumba.

*P. e. virginalis* Hartert, 1896 - islands of Tanahjampea, Kalao and Kalaotoa (S of Sulawesi).

*P. e. elegans* Temminck, 1836 - breeds C Lesser Sundas (Sema, Timor, Kisar, possibly Roti); also recorded (probably only as non-breeding visitor) on islands of Ruang and Tabulandang (N of Sulawesi), Ternate (W of Halmahera), Banggai Is, Sula Is (Taliabu, Mangole, Sanana) and C Moluccas (Buru, Boano, Seram).

*P. e. vigorsii* Gould, 1838 - S Moluccas (Banda, Kasiui, Kur, Tiur), Kai Is (including Taam, Tayandu) and E Lesser Sundas (Damar, Babar); also recorded, probably as migrant, on Seram and Tanimbar Is.

blue feathers in wing, lower belly pinkish, orange tip of bill. Races differ mainly in head pattern: *virginalis* resembles nominate, but broader lateral crownstripe pale rufous, throat more extensively white; *vigorsii* has crownstripe paler behind eye, both chin and throat white, underparts slightly darker; *concinna* has reddish-buff lateral crownstripe gradually becoming white and then pale blue behind eye, more black on belly; *maria* has lateral crownstripe paler than previous, more red and little black on belly, less white in wing. VOICE. On Sumba "ka-wha-kil" or "hwp-hwp-pw", also single descending "pwer"; on Lombok "kphwrrr-whip" c. 1 second long and repeated at variable intervals; on Timor "kuw-whaa-whaa", repeated every 3-6 seconds; in Banggai Is. "perriew-priew"; in Sula Is described as "kwuwik-kwk", but on Kai Is more as "wrrek-wrrek" or "wrrek-wrrek-wrrek"; on Flores, however, more disyllabic "kwwee-kwill", repeated every 3 seconds.

**Habitat.** Variety of forest types, both dry and wet, including humid primary forest, dry monsoon forest, edges, heavily degraded forest, also logged and selectively logged monsoon forest and scrub, as well as areas dominated by cultivation. Also in swamp-forest on Timor. Lowlands to 1200 m, to 1400 m on Sumbawa and Flores; occasional records at higher altitudes presumably refer to migrants.

**Food and Feeding.** Stomachs have been found to contain small beetles, lepidopterans and snails. On Sumbawa, seen foraging in association with Emerald Doves (*Chalcophaps indica*). In Banggai Is. seen jumping up to catch flying insects.

**Breeding.** Main season apparently Apr-Aug, but probably throughout year. Single nest described, from Babar, built of broadleaves and leaf skeletons held together by a few large sticks, and lined with fine black rootlets. Clutch 2-3 eggs, glossy white with brown-lilac spots and patches and underlying pale grey-lilac spots, average c. 27 × 21 mm; no information on incubation and fledging periods.

**Movements.** Poorly known. Resident on some islands, e.g. Flores and Sumba. Nominant race appears to undertake some seasonal inter-island movements, moving N after breeding, possibly owing to food shortage. Race *vigorsii* also appears to make some movements, but details little understood. Jan record of this race on Kaledupa, in Tukanbesi Is (SE of Sulawesi), considered of doubtful provenance, possibly the result of escape of a captive individual; present in Tanimbar Is during period of highest rainfall, Dec-Feb, but apparently absent during driest months, Jun-Oct, although it is suggested that this may be merely that birds do not call during this period and so are not detected.

**Status and Conservation.** Not globally threatened. Widespread and not uncommon, though inter-island movements make it difficult to provide accurate assessments in some cases. On many islands, such as Lombok, Sumbawa and Flores, it is reported as common, and population of Sumba was estimated at 11,000 birds in 1994. Common on Banda during Sept-Oct, on Damar in Nov-Dec, and in Tanimbar Is in Dec-Feb; moderately common on Timor in Dec-Jan; on Taliabu, however, found to be rare and possibly near-threatened, with only five birds located during survey of Sept-Oct 1991. Appears to be at least partly adaptable to disturbed habitats. No reports from cagebird trade. Has been bred in captivity.

**Bibliography.** Andrew (1992), Bishop (1992), Bishop & Brickley (1999), Bostock & Sujatnika (1993), Butchart *et al.* (1993), Coates & Bishop (1997), Davidson *et al.* (1994, 1995), Dickinson & Dekker (2000), Dickinson *et al.* (2000), Dutoit (1995), Eek (1977), Ellis (2002), Indrawan *et al.* (1997), Inskipp *et al.* (1996), Jepson & Monk (1995), Johnstone *et al.* (1996), Jones, Juhaeni *et al.* (1994), Jones, Linsley & Marsden (1995), Linsley *et al.* (1999), MacKinnon & Philipps (1993), Mayr (1944), Pagel (2000, 2001), Riley (1997a), Schodde & Mathews (1977), Stattersfield & Capper (2000), Stones *et al.* (1997), Sujatnika *et al.* (1995), Trainor (2002), Verhoeve & Holmes (1999), White & Bruce (1986).

## 28. Noisy Pitta

### *Pitta versicolor*

**French:** Brève versicolore      **German:** Lärmpitta      **Spanish:** Pita Bulliciosa  
**Other common names:** Buff-breasted/Blue-winged(ly) Lesser Pitta

**Taxonomy.** *Pitta versicolor* Swainson, 1825, "Australasia" = New South Wales, Australia. Formerly considered conspecific with *P. elegans* or with *P. iris*, but seems best regarded as forming a superspecies with those together with *P. anerythra*. Population from Cairns region of NE Queensland sometimes separated as race *intermedia* on basis of size and plumage characters, but variation in these parameters is clinal from N to S. Two subspecies recognized.

#### **Subspecies and Distribution.**

*P. v. similima* Gould, 1868 - islands in Torres Strait, and NE Queensland (from Cape York Peninsula S to Cairns District); some migrate to S New Guinea.

*P. v. versicolor* Swainson, 1825 - Cairns District S to E New South Wales (S to R Hunter region).

**Descriptive notes.** 19-21 cm; male 70-112 g, female 70-128 g. Adult has forecrown to nape chestnut with narrow black median stripe, rest of head, hindneck and throat black; upperparts green, rump shining turquoise-blue, tail black with green tip; lesser wing-coverts glossy turquoise, rest of coverts bright green; flight-feathers black, secondaries edged green, small white patch near base of primaries; underparts golden buff, green tinge on sides of breast, black belly patch, scarlet on lower belly and undertail-coverts; iris dark brown; bill black; feet flesh-pink to pale purplish-flesh. Sexes alike. Dusky stripes found on green and blue upperparts of 68% of

70 adults examined (both sexes). Juvenile is duller, throat whitish, no blue on wing, orange tip and base of bill. Race *similima* is smaller, brighter green above, deeper yellow-brown below. VOICE. Short low whistle, "hwhup-hu-whip" or "phwheat-ah-wheat" c. 1-1.5 seconds long, often likened to human phrase "walk to work" or "want a watch", usually repeated twice; single mournful whistle by female; sharp "keow", apparently as warning; also soft purring like that of a cat.

**Habitat.** Predominantly rainforest with luxuriant to sparse undergrowth, mostly in wet gulleys and river valleys; also dry sclerophyll forest and wet eucalyptus (*Eucalyptus*) forest. Also found in mangroves and coastal thickets outside breeding season, and in New Guinea found in monsoon woodland; migrants occasionally recorded in urban gardens. Sea-level to 1500 m.

**Food and Feeding.** Chiefly snails and insects (beetles, ants), also earthworms, spiders, woodlice (Isopoda); occasionally shrimps and crabs, also leeches, even small lizards. Some vegetable matter sometimes taken, e.g. fruits and berries, seeds. Stones or hard wood used as "anvils" to smash snail shells; small lizards bashed against logs before swallowing. Forages on ground, singly or in loose contact with partner. Hops about, turns over dead leaves and debris, and tosses them aside with bill; also scratches at soil and leaf litter.

**Breeding.** Laying recorded Oct-Apr (mostly Nov-Jan) in N and Jul-Feb (mostly Oct-Dec) in S. Domed nest c. 30 cm tall and 20-28 cm in diameter, with side entrance 8-11 cm across, built by both sexes from twigs, leaves, ferns, roots, moss, plant fibres and bark strips on a platform of twigs, lined with finer material, often with stick ramp 15-30 cm long leading to entrance; mammal dung or mud often spread over ramp and inside nest; usually on ground, sometimes up to 2.7 m up in tree niche or other vegetation. Clutch 3-5 eggs, average 2.9 in N but 3.6 in S, glossy white to blue-white with dark purple-brown blotches and spots and blue-grey underlying spots, mostly near large end, average c. 30 × 24 mm in N and c. 33 × 25 mm in S; incubation by both sexes, period 15-17 days; chicks fed by both sexes, fledging period c. 14 days; in captivity, chicks fledged after 15-20 days, independent after 32 days. Hatching success for 16 eggs in five clutches was 31%. Nests preyed upon by snakes, e.g. eastern tiger snake (*Notechis scutatus*).

**Movements.** Not well known. Partial migrant in N, where some make post-breeding migration N to S New Guinea in Feb-Apr, returning S in Oct-Dec. Probably more or less resident elsewhere, but some local movement; some altitudinal shifts and small-scale dispersal probably occur in most of range, mainly in S; possibly a degree of nomadism outside breeding season.

**Status and Conservation.** Not globally threatened. Moderately common to rather scarce; common at only a few sites, including Yarraman District SE (Queensland) and Georgica (New South Wales); rare in New Guinea. Density of 7-8 pairs in 6 ha of rainforest in New South Wales. Very silent outside breeding season, which may in part explain the comparatively few records of this species. Adversely affected by habitat loss associated with agricultural expansion, leading to declines and local extinctions in several parts of range. Formerly common at Nanango (SE Queensland), but natural subtropical rainforest now replaced by hoop pine (*Araucaria cunninghamii*) plantations and only small forest remnants of c. 32 ha survive; was last recorded there in 1976, and believed now to be extinct; probably extinct also on Redcliffe Peninsula. Decline noted also in NE New South Wales as a result of heavy disturbance and degradation of lowland rainforest. In addition, is often killed by cats, more rarely by dogs; sometimes killed on roads and through collisions with windows. No records from cagebird trade.

**Bibliography.** Alley (1979), Barker & Vestjens (1990), Beehler & Finch (1985), Beehler *et al.* (1986), Bell (1968), Berulidsen (1980), Berulidsen & Uhlenhuth (1995), Blakers *et al.* (1984), Braithwaite (1972), Cayley (1964), Chan (2001), Christidis & Boles (1994), Coates (1990), Coates & Peckover (2001), Dawson *et al.* (1991), Draffan *et al.* (1983), Eastwood & Gregory (1995), Finch (1980b, 1981), Fisher (1975), Friith (1999), Friith & Friith (1991, 1992), Fulton & Boles (2002), Hall (1974, 1999), Higgins *et al.* (2001), Hoberoff (1992), Kikkawa (1970), King & King (1974), Kirkup (1995), Laurance & Grant (1994), Lavery (1986), Lavery *et al.* (1968), Lea & Gray (1935), Lindsey (1992), Macdonald (1988), McAllan & Bruce (1989), Mees (1982), Morcombe (2000), Nagel (1986), Nilsson (1990), Norris (1964), Parrish (1983), Pizzey & Knight (1997), Rand & Gilliard (1967), Redhead (1988, 1990), Rose (1999), Schodde & Mason (1999), Schodde & Tidemann (1986), Simpson & Day (1998), Snedie (2002), Stattersfield & Capper (2000), Steward (1984), Storr (1984), Sutton (1990), Taylor & Taylor (1995), Templeton (1992), Threlfo (1983), Totterman (1999), Trounson & Trounson (1987), Trudgeon (1971), Warren & Barwell (1987), Wieneke (1988), Woodall (1993, 1994, 1997), Zimmermann (1996, 1997).

## 29. Black-faced Pitta

### *Pitta anerythra*

**French:** Brève masquée      **German:** Schwarzgesichtpitta      **Spanish:** Pita Carinegra  
**Other common names:** Masked/Solomons Pitta

**Taxonomy.** *Pitta anerythra* Rothschild, 1901, Santa Isabel, Solomon Islands.

Possibly forms a superspecies with *P. elegans*, *P. versicolor* and *P. iris*. Three subspecies recognized.

#### **Subspecies and Distribution.**

*P. a. pallida* Rothschild, 1904 - Bougainville (N Solomons).

*P. a. nigrifrons* Mayr, 1935 - Choiseul (C Solomons).

*P. a. anerythra* Rothschild, 1901 - Santa Isabel (C Solomons).

**Descriptive notes.** 15-17 cm. Adult has crown rich chestnut, rest of head black, tinged buff on nape; hindneck and upper mantle black, rest of upperparts bright green, rump feathers tipped blue-green, tail dull green with black base; lesser upperwing-coverts mostly glistening turquoise, rest of coverts green; flight-feathers black, secondaries edged green, small white patch on primaries; underparts ochre-buff, darkest on breast; iris dark brown; bill blackish; feet pale greyish to bluish-slate. Sexes alike. Dusky stripes found on green upperparts of 8% of 36 adults examined (both sexes, all races). Juvenile not described. Race

*nigrifrons* has more black on forecrown, underparts deep ochre but variable; *pallida* is larger, has head black with little or no chestnut on nape, and is much paler, almost whitish, below. VOICE. On Santa Isabel, harsh and rather unmelodic far-carrying "hww-hwe(-)hww" or "hwe(-)hww", rising sharply at end.

**Habitat.** Primary and secondary forest, also scrub and small forest fragments mixed with old gardens. In the past was known to occur in coastal plains and alluvial valleys, and in forested mountain valleys. Lowlands to 600 m.

**Food and Feeding.** Feeds on worms, snails and insects.

**Breeding.** An egg collected in mid-May and female in breeding condition in late Jul on Bougainville; males in post-breeding moult in Jul on Santa Isabel. Bulky nest constructed of leaves and moss,

placed on or near ground. Clutch size unknown; egg collected on Bougainville (*pallida*) was creamy white, spotted with brownish-red and underlying greyish-mauve, size 30.8 × 25 mm. No other information.

**Movements.** Probably resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Solomon Group EBA. Very small range, and global population probably very small. No recent records from Bougainville, where not uncommon in early decades of 20th century. Not found on Choiseul in recent searches by ornithologists. In 1994 found to be common in SE Santa Isabel at Tirotonga, where up to three individuals calling simultaneously. Unconfirmed reports from two islands adjacent to Choiseul (Kolombangara, Vangunu), but species thought unlikely to breed there. May have declined steeply in most of range, but lack of access to Bougainville hinders assessment of species' current status; the possibility that it has an extremely patchy distribution or that it was always relatively rare in most of range cannot be excluded. Recently suggested that this weak-flying species' inability to colonize other areas by flying over water renders it liable to extinction. Otherwise, forests in alluvial valleys, which once represented an apparently important habitat for the species, are threatened by extensive logging and have almost disappeared in many places. On other hand, it appears not to be subject to serious predation by introduced mammals; on Santa Isabel found near settlements with cats, dogs and rats (*Rattus*). Conservation initiatives include further fieldwork to establish this pitta's current distribution and numbers, and to determine its ecological requirements; setting-up of an ecotourism facility at Tirotonga; and a programme aimed at raising public awareness, first on Santa Isabel. No reports from cagebird trade.

**Bibliography.** Anon. (1991), Buckingham *et al.* (1995), Coates (1990), Collar & Andrew (1988), Collar *et al.* (1994), Diamond (1987), Doughty *et al.* (1999), Dutton (2000, 2001), Gibbs (1996), Gregory (2000), Hadden (1981), Kratter, Steadman, Smith & Filardi (2001), Kratter, Steadman, Smith, Filardi & Webb (2001), Mayr (1935, 1936, 1945), Mayr & Diamond (2001), Rothschild & Hartert (1905), Stattersfield & Capper (2000).

### 30. Rainbow Pitta

#### *Pitta iris*

**French:** Brève iris

**German:** Regenbogenpitta

**Spanish:** Pita Arcoiris

**Other common names:** Black-breasted Pitta

**Taxonomy.** *Pitta iris* Gould, 1842, Cobourg Peninsula, Northern Territory, Australia.

Sometimes considered conspecific with *P. versicolor*, but differs significantly in plumage, biometrics and voice; probably better treated as forming a superspecies with that species together with *P. elegans* and *P. anerythra*. Two subspecies recognized.

**Distribution and Subspecies.**

*P. i. johnstoneiana* Schodde & Mason, 1999 - NW Australia in NW Kimberley Division (Napier Broome Bay S to R Prince Regent), including Augustus I and islands in Admiralty Gulf.

*P. i. iris* Gould, 1842 - N Northern Territory, from Melville I and Darwin E to Groote Eylandt, including Tiwi Is.

**Descriptive notes.** 16-18 cm; 55-72 g. Adult has head and neck black with broad chestnut lateral crownstripe, upperparts bright olive-green, sometimes a narrow silvery green-blue band across uppertail-coverts, tail green with black base; large shining violaceous-blue patch on lesser coverts, rest of upperwing-coverts green with golden gloss; flight-feathers blackish, secondaries edged green, primaries tipped paler and with small white spot near base; all black below, except for some buff feathers on lower flanks, scarlet lower belly and undertail-coverts; iris dark brown; bill black; feet flesh-coloured to silvery grey or reddish-grey. Sexes alike. Dusky stripes found on green and blue upperparts of 60% of 23 adults examined (both sexes, both races). Juvenile is duller than adult, little or no chestnut on crown, little blue on wing, white-mottled throat, pale pinkish vent,

orange base of bill. Race *johnstoneiana* is slightly smaller, with larger rufous-brown stripe on side of crown, larger white wing spot. Voice. Double whistle, "teow-whit, teow-whit" or "choowip-choowip", often likened to human phrase "I want a whip", or sometimes first note omitted, often repeated in series during Oct-Dec; loud sharp "keow" as alarm; also soft cat-like purr, "brrr", given in display.

**Habitat.** Monsoon rainforest, gallery forest and vine scrub, also eucalypt (*Eucalyptus*) forest, and sometimes found in bamboo thickets and mangrove edges; occasionally recorded in pine (*Pinus*) plantations. Sea-level to 380 m.

**Food and Feeding.** Worms, snails, insects and their larvae, also other arthropods such as spiders, centipedes (Chilopoda), millipedes (Diplopoda); occasionally frogs, small skinks (Scincidae); rarely, fruit of *Carpentaria* palms. Insects mainly beetles, cockroaches (Blattodea), ants, orthopterans. Earthworms and snails form major part of diet during Oct-Apr wet season; insects eaten mostly during dry season. Snail shells smashed against branch or exposed roots; large prey seized with bill and shaken, dropped, then picked up and shaken again, process repeated several times. Forages on ground, making a number of hops and then pausing to inspect leaf litter; scratches soil or litter with foot, tosses aside leaves with bill.

**Breeding.** Dec-Apr, occasionally later, in W, and mainly Oct-Mar in Northern Territory; often two broods raised in a season. Maintains territory of over 10,000 m<sup>2</sup>. Usually domed nest c. 22 cm tall and c. 26 cm in diameter, with side entrance c. 9.5 cm across, built by both sexes from sticks, bark strips, dead vines, leaves, grass, sometimes almost entirely from bamboo leaves, and lined with finer material; base of entrance sometimes covered with faecal pellets of mammalian herbivores; placed up to 8.5 m (mean 4.5 m) above ground in tree or palm, often on top of stump, less often on ground against buttress roots. Clutch 3-4 eggs, rarely 5, glossy creamy white with dark brown or red-brown rounded spots and underlying grey-lilac spots, average c. 26 × 21 mm; incubation by both sexes, period 14 days; both also take equal share in feeding chicks, in 92 feeds at eight nests food delivered at average interval of 7.5 minutes; young leave nest after 13-15 days, independent c. 2 weeks later. Success sometimes low; of 66 nests over several years at one site, 74.2 % lost through predation. Recorded longevity in wild at least 9 years.

**Movements.** Sedentary.

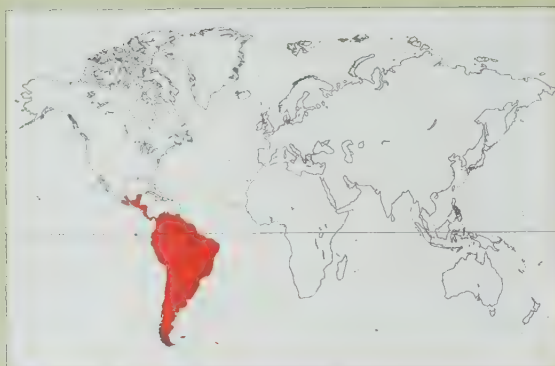

**Status and Conservation.** Not globally threatened. Restricted-range species: present in North-west Australia EBA. Locally common. Nominat race common around Darwin; in Northern Territory, density of 1 bird/ha recorded in Kakadu National Park; mean of 0.4 birds/ha at various sites in Top End, where species recorded in 33 of 48 monsoon rainforests visited; and 7 individuals calling in c. 4 ha on Cobourg Peninsula. Deterioration of monsoon forest and edge caused by fires could possibly have adverse effect on its numbers, although detailed studies did not find this to be so. W population (*johnstoneiana*) less well known; formerly somewhat more widespread; on Mitchell Plateau (Kimberley), vegetation partially destroyed by feral cattle (*Bos*), resulting in greatly reduced area of feeding habitat and marked decline in numbers of this subspecies. Not reported in cagebird trade.

**Bibliography.** Barker & Vestjens (1990), Beruldsen (1980), Blakers *et al.* (1984), Cayley (1964), Christidis & Bales (1994), Crawford (1972), Ford (1978), Friith & Hitchcock (1974), Glover (1968), Hall (1974), Higgins *et al.* (2001), Johnstone & Burbidge (1991), Le Souët (1901), Lindsey (1992), Macdonald (1988), Meyer de Schauensee (1957), Morcombe (2000), Pizzey & Knight (1997), Rose (1999), Schodde & Mason (1999), Schodde & Tidemann (1986), Simpson & Day (1998), Stattersfield & Capper (2000), Storr (1977, 1980), Trounson & Trounson (1987), Woinarski (1993), Woinarski *et al.* (1989), Zimmermann (1996, 1997).

Class AVES  
Order PASSERIFORMES  
Suborder FURNARIII  
**Family FURNARIIDAE (OVENBIRDS)**

- Small to medium-sized birds, most with short, rounded wings, often strong legs and feet, often long tail with minor to major strengthening of feather shafts; plumage mostly some shade of brown, ranging from greyish or blackish to olivaceous or reddish.
- 10-26 cm.

- Neotropical Region.
- All habitats.
- 56 genera, 236 species, 588 taxa.
- 26 species threatened; none extinct since 1600.

### Systematics

Regarding the family as a whole, Furnariidae can be characterized by extremes. At one end, it exhibits exceptional to unparalleled heterogeneity and diversity in nest architecture, structural morphology, foraging behaviour, habitat occupancy and physiological tolerance. At the opposite end, it displays remarkable homogeneity in coloration, social systems, diet and vocalizations.

The ovenbirds (Furnariidae) have been recognized as a natural group by ornithologists for at least 150 years. The only serious controversy has concerned whether the woodcreepers (Dendrocolaptidae) are nested within the ovenbirds or should be ranked as the sister taxon to them, either at family or subfamily level. Although the argument is still largely unresolved, these two groups of birds have for more than a century been considered more closely related to each other than either is to any other lineage in the class Aves. This is due in part to the fact that they share a unique character of the syrinx, namely the presence of two intrinsic muscles, a character noted by earlier avian anatomists in the nineteenth century. Support for the hypothesis of a close relationship between the two has come more recently from genetic data, the result of studies of both DNA-DNA hybridization and DNA-sequencing.

The name Furnariidae comes, as is to be expected, from the family's type genus, *Furnarius*, which in Latin means "baker" or "one who keeps an oven". This genus name was introduced by Vieillot, basing himself on Buffon's "Fournillier", and presumably alludes to the ovenlike shape of the adobe mud nest of the Rufous Hornero (*Furnarius rufus*), likewise found in at least three of its congeners. Although this nest type is, in fact, very unusual within Furnariidae as a whole, the family name does at least draw particular attention to nest shape, which is highly appropriate for a family known for its distinctive and often absurdly large nests.

As with many Neotropical Passeriformes, the fossil record for the family is extremely weak: only four fossil species attributed to the Furnariidae are known, most from single specimens, and all from the Pleistocene. Two species are assignable to modern genera, *Cinclodes* and *Pseudoseisura*, whereas the other two belong to the fossil genus *Pseudoseisuropsis*.

Thus, the fossil record so far provides no help in determining the origins, history, biogeography and relationships of the family. Nevertheless, if traditional, conventional biogeographical interpretations have any predictive value, the ovenbirds are certainly of South American origin. Perhaps no other avian family is so

closely associated with a continent as is Furnariidae with South America. Of the 236 taxa currently ranked as species, 210, or 89%, are endemic to South America and its continental islands. All but two of the remaining 26 species occur in Middle America, the exceptions being a single species in the Falkland Islands, in the South Atlantic, and one in the Juan Fernández Islands, off Chile, in the Pacific Ocean. Furthermore, as 20 of the 24 furnariids found in Middle America occur also in South America, only four of the family's 236 species, less than 2%, are restricted to Middle America. These are the Rufous-breasted Spinetail (*Synallaxis*

*The Necklaced Spinetail* presents a quandary to taxonomists. Currently included within the genus *Synallaxis*, it differs in plumage and vocalizations from, and is more arboreal in habits than, its undergrowth-skulking congeners. Species limits aside, there is very little serious debate about the wider taxonomy of the ovenbirds in general. The one exception concerns the treatment of the woodcreepers (Dendrocolaptidae) in relation to the ovenbirds. Although structural morphology and genetic research indicate that maintaining them as a monophyletic group is probably correct, recent genetic data indicate that they may be a lineage within, rather than the sister-group to, the ovenbirds.

[*Synallaxis stictothorax maculata*, Lambayeque, Peru.  
Photo: J. Dunning/VIREO]

The largely terrestrial **Rufous-banded Miner** and its relatives in the genus *Geositta* are separated from the other ovenbirds by a key difference in syrinx structure and the presence of a notched tail. Miners differ further in being strongly associated with open habitats. This association accounts for many of the other differences that are apparent, such as aerial song-flights, strong flight, and striking wing and tail patterns. The name "miner" presumably refers to the fact that they excavate nest-burrows or appropriate those dug by other birds and mammals.

*erythrothorax*), the Ruddy Treerunner (*Margarornis rubiginosus*), the Beautiful Treerunner (*Margarornis bellulus*), which lives in mountains within sight of Colombia, and the Streak-breasted Treehunter (*Thripadectes rufobrunneus*). In addition, most of the Middle American furnariids reach no farther north than Costa Rica, and only six extend as far as southern Mexico; none occurs in the West Indies. In comparison with the many other bird families of the Neotropics, therefore, the truncation of the northern limits of the Furnariidae is exceptionally severe.

From the above details, therefore, it is evident that the ovenbirds represent a truly South American radiation. In contrast

The cocked tail and rocky habitat of the **Straight-billed Earthcreeper** are typical of the genus *Upucerthia*. Earthcreepers favour rocky ravines with shrubs, clumps of grass and scree and boulders for shelter. Other features of this terrestrial genus include plain, rather uniform plumage (although some species exhibit striking wing markings), a long and often decurved bill, and the fact that, like the miners (*Geositta*), its members nest in burrows. Earthcreepers are found mainly in the high-altitude habitats of the Andes, although some occur at lower elevations and one at sea-level. Many consider the curve-billed members of this genus as demonstrating convergent evolution with the thrashers (*Toxostoma*) of North America.

to most other Neotropical lineages, Furnariidae is one of the predominant bird families at the southern end of the continent, in the cold higher latitudes of South America. Whereas the typical antbirds (*Thamnophilidae*), the ground-antbirds (*Formicariidae*), the manakins (*Pipridae*), the cotingas (*Cotingidae*), the motmots (*Momotidae*), the puffbirds (*Bucconidae*), the jacamars (*Galbulidae*) and the toucans (*Ramphastidae*), as well as the American representatives of the trogon family (*Trogonidae*) and the barbet family (*Capitonidae*), barely make it farther south than the subtropics of northern Argentina, the ovenbirds are prominent members of the avifauna all the way south to the coldest and bleakest parts of Tierra del Fuego. Although the tapaculos (*Rhinocryptidae*) extend as far south as the furnariids, they are not represented in the Guianan Shield or the Patagonian steppe regions, nor are they so numerous in terms of number of species. This same pattern of familial truncation is mirrored by elevational patterns of distribution in the Andes, where many of the core Neotropical families drop out precipitously with increasing altitude, and few ascend beyond the timber-line ecotone. Of the major Neotropical families, only the tinamous (*Tinamidae*), the hummingbirds (*Trochilidae*) and the tyrant-flycatchers (*Tyrannidae*) have members living in the *puna* zone. Hummingbirds and tyrant-flycatchers, in contrast to the Furnariidae, are well represented in northern Central America, with several endemic genera and many endemic species, and both are reasonably well represented in the Nearctic Region. This leaves the much less species-rich tinamous as the only competitor for the title of "most South American" bird family. The inclusion of the woodcreepers in the Furnariidae would do little to alter this pattern, except that the woodcreepers are proportionally better represented in Central America and extend farther north in Mexico.

The biogeography of the furnariid species currently placed in monotypic genera may also provide hints as to the history and, perhaps, the geographical origins of the family. The assignment of any species to a monotypic genus is to some degree, of course, arbitrary, and is also dependent on whether discrete geographical variation within the lineage is considered to represent differentiation at the species level or at the subspecies level; however, it is at least somewhat indicative of morphological distinctiveness within the family. With that important caveat in mind, it is still of some interest that two particular, region-restricted habitats each hold four monotypic genera of furnariids. One is the Atlantic Forest region of south-eastern South America, to which the Itatiaia Spinetail (*Oreophylax moreirae*), the Canebrake Groundcreeper (*Clibanornis dendrocolaptoides*), the Pale-browed Treehunter

Placed in a monotypic genus closely related to the other earthcreepers (Upucerthia), the well-marked **Band-tailed Earthcreeper** inhabits shrubby plains, where it is largely terrestrial. One factor distinguishing this species from the Upucerthia earthcreepers is that it constructs large twig nests in low bushes, these bearing a resemblance to the nests built by canasteros (Asthenes). Currently, the taxonomic relationship between Upucerthia and Eremobius is uncertain.

[*Eremobius phoenicurus*, Argentina.  
Photo: Roland Seitre/Bios]

(*Cichlocolaptes leucophrys*) and the Sharp-billed Treehunter (*Heliobletus contaminatus*) are confined. The other is the emergent vegetation of marshes of subtropical southern South America, where the Curve-billed Reedhaunter (*Limnornis curvirostris*), the Straight-billed Reedhaunter (*Limnornis rectirostris*), the Bay-capped Wren-spinetail (*Spartonoica maluroides*) and the Wren-like Rushbird (*Phleocryptes melanops*) are found. The last of those also extends into the Andes. In the humid forests of the Andes there are three further species each placed in a genus of its own: the White-browed Spinetail (*Hellmayrea gularis*), the Spec-

tacted Prickletail (*Siptornis striatocollis*) and the Rusty-winged Barbtail (*Premnornis guttuligera*). Similarly, Amazonia contains three such species, the Orange-fronted Plushcrown (*Metopothrix aurantiaca*), the Point-tailed Palmcreeper (*Berlepschia rikeri*) and the Chestnut-winged Hookbill (*Ancistrops strigilatus*).

A further three regional habitat types harbour each at least two single-species genera. The arid *caatinga* region of extreme east Brazil is the home of the Red-shouldered Spinetail (*Gyalophylax hellmayri*) and the Great Xenops (*Megaxenops parnaguai*), the southern beech forests of temperate southern South America harbour Des Murs's Wiretail (*Sylviorthorhynchus desmursii*) and the White-throated Treerunner (*Pygarrhichas albogularis*), while the savannas and scrub of southern South America contain the Lark-like Brushrunner (*Coryphistera alaudina*) and the Firewood-gatherer (*Anumbius annumbi*).

Taken as a whole, the monotypic genera of furnariids have a distribution restricted to South America. More importantly, however, this is concentrated in the eastern and southern portions of the continent, rather than the northern and western sections. Those first two areas are also among the oldest parts of the continent in terms of surface geology and, presumably, habitat types.

With regard to general plumage, voice and behaviour, the woodcreepers cannot be readily distinguished from the ovenbirds. Although the scansorial, or branch-climbing, behaviour and concomitant morphological adaptations have led to the recognition of Dendrocolaptidae as a family separate from Furnariidae, the basis for this is weak. The only character that unambiguously diagnoses the Dendrocolaptidae as a monophyletic group is its pattern of body pterylosis, involving a configuration in the ventral feather tract found in no other passeriform family. This was outlined in a study by M. Clench, but a limited number of taxa were included in her sample, so further work is needed before this single character becomes codified as defining the woodcreepers.

Otherwise, the climbing behaviour and adaptations of the woodcreepers are not much greater than those of the genera *Pygarrhichas*, *Margarornis* or *Berlepschia* within the present family. All woodcreepers have a tail in which the shafts are stiffened throughout and also terminate in slightly to strongly decurved, protruding spines. While no ovenbird possesses an identical tail, some species, particularly the White-throated Treerunner, come so close to this condition that the use of this character as a

The boldly marked and terrestrial **Crag Chilia** favours sparsely vegetated, arid rocky slopes and cliffs. It hunts for prey over the rock surfaces, cracks and fissures, and builds a twig nest hidden in a rock crevice. This is a restricted-range species found only in a relatively small area of Chile. It occupies a monotypic genus having affinities with the earthcreepers (Upucerthia) and, possibly, also the genus Cinclodes. The ovenbird family is notable for including a high proportion of species that, like the Crag Chilia, are dependent on rocky habitats for feeding and the provision of nest-sites.

[*Chilia melanura melanura*, Farellones, Cordillera de los Andes de Santiago, Región Metropolitana, Chile.  
Photo: Gonzalo González C./ Science Adventure]

Like most members of the genus *Cinclodes*, the sturdily built, thrush-like **Dark-bellied Cinclodes** is closely associated with water, frequenting riparian habitats, unexposed shorelines and lake margins. The scientific name of the genus reflects superficial similarities to the dippers (*Cinclus*). Resident in coastal Tierra del Fuego, the Dark-bellied Cinclodes, in common with many of its congeners, seems able to tolerate extremely severe climatic conditions. Perhaps a key to this tolerance of harsh habitats is the fact that this cinclodes, like many species in the Furnariidae, shelters the eggs and young by placing its nest at the end of a burrow excavated into the ground.

[*Cinclodes patagonicus patagonicus*,

means of justifying either monophyly or family rank appears rather arbitrary. Although many sources state that no furnariids persistently use the tail as a brace during climbing, the *Margarornis* treerunners do this at least as much as do some woodcreepers, such as the *Dendrocincla* species, and many other furnariids use the tail occasionally as a brace against branches during certain foraging manoeuvres. In addition, the complex plumage patterns of many woodcreeper taxa are suspiciously close in many details to those of certain ovenbirds. Examples include *Glyphorhynchus*, which resembles *Xenops*, and *Xiphorhynchus*, which is closely approached in appearance by the furnariid genera *Premnornis*, *Cichlocolaptes* and *Hyloctistes*, while the Tawny-winged Woodcreeper (*Dendrocincla anabatina*) bears a remarkable resemblance to the *Anabacerthia* foliage-gleaners.

The Dendrocolaptidae have large horns on the processi vocales of the syrinx, but these are also found in the furnariid genus *Geositta*. They also all have holorhinal nares, rounded and with the posterior end anterior to the naso-frontal hinge, whereas the Furnariidae have nares that are narrow but rounded posteriorly (pseudoschizorhinal). A. Feduccia, however, has demonstrated that some furnariids tend towards the holorhinal condition, thus casting doubt on the validity of this character for separating the lineages. This tendency is most evident in the species in the philydorine assemblage (see below), which are closest to the woodcreepers in other aspects of morphology and plumage.

As pointed out by R. Ridgway, the two families differ in foot morphology. In the Dendrocolaptidae, the outer toe is almost as long as the middle toe and is much longer than the inner toe, while the hallux, or hind toe minus claw, is shorter than the inner toe; the outer and middle toes are fused basally. In the Furnariidae, the outer toe is shorter than the middle one, the hallux is not shorter than the inner toe, and the outer and middle toes are fused for only a short distance, if at all. Nevertheless, these characters, as well as others that reveal differences between the ovenbirds and the woodcreepers, such as limb proportions, the configuration of the distal end of the tarsometatarsus and the shape of the proximal end of the tibiotarsus, are merely reflections of adaptations for climbing. Indeed, those members of the Furnariidae, especially in the philydorine group, that do more climbing also exhibit variations that tend towards the characters of the woodcreepers or are indistinguishable from them.

Whether the woodcreepers are themselves monophyletic is the critical first step towards according them family rank (see page 358). The monophyly of the woodcreepers, however, is a separate issue from that of whether they should or should not be included in the Furnariidae. The fundamental question concerns whether some ovenbirds are more closely related to woodcreepers than they are to other furnariids, in other words, whether the Furnariidae are paraphyletic with respect to the Dendrocolaptidae. If that is the case, then the woodcreepers cannot be recognized as a separate family, or a separate group taxon of any rank, under

The **Wing-banded Hornero** has a distinctive short-tailed and long-billed appearance and a striking supercilium.

It feeds primarily on the ground, where it struts around in a characteristic way, probing the soil and flicking aside leaves and detritus while searching for food, behaviour typical of the genus *Furnarius*. Unlike the other five species, however, the Wing-banded Hornero does not build an oven-like mud nest.

It is these peculiar nests that have given the family as a whole its name.

Horneros are typically found in lightly wooded and open areas, often near water.

Some are conspicuous in gardens and near human habitation, and where this is the case they are often well-known and celebrated species.

A chunky, marsh-dwelling ovenbird, the ordinarily skulking **Curve-billed Reedhaunter** is the sole member of its genus. Although the Straight-billed Reedhaunter (*Limnornis rectirostris*) is occasionally included within the same genus, the two differ in morphology, nest architecture and egg coloration. In terms of plumage and feeding behaviour, this species is remarkably similar to the Old World reed warblers (*Acrocephalus*), a further example of convergent evolution following the dynamic radiation of the Furnariidae. The Curve-billed Reedhaunter has a rather small geographical range, occurring in wet reedbeds in eastern Argentina, Uruguay and southern Brazil.

the principles of phylogenetic classification. Only if the woodcreepers and the ovenbirds are each independent monophyletic lineages, with all woodcreepers more closely related to one another than to any furnariid and, likewise, all ovenbirds closer to one another than any is to any woodcreeper, can they be accorded separate, equivalent taxonomic ranks such as family status. It is hoped that ongoing studies of molecular phylogeny will shed further light on this complex issue.

Of further relevance is the matter of determining which families are closest to these two groups. Since anatomical studies made in the nineteenth century, the proposed closest relatives have come from within the suboscine families known collectively as the

tracheophones. All families in this lineage, which also includes Thamnophilidae, Formicariidae, Conopophagidae and Rhinocryptidae, share unique morphology of the syrinx, and its monophyly is supported by more recent information derived from studies centred on DNA-DNA hybridization and DNA sequences. Within that cluster of families, however, the relationships of the furnariids and the dendrocolaptids to the rest remain to be resolved. C. G. Sibley and J. E. Ahlquist interpreted their DNA-DNA hybridization data as indicating that the sister-group was a cluster of three families, Formicariidae, Conopophagidae and Rhinocryptidae, which they treated as forming a superfamily, Formicarioidea. Subsequent analyses of DNA-sequence data by

The small size and acrobatic abilities of the **Plain-mantled Tit-spinetail** allow it to search for food on these delicate, slender flower stems. This species, as others of the genus, is characterized by its graduated and pointed rectrices, often forming a double-pointed tail tip. Variation in tail structure is extreme throughout the ovenbird family, and this is reflected in many of the English and scientific names of the genera. Moreover, the specific name of this species alludes to a perceived convergence with the Old World long-tailed tits (*Aegithalos*). Most tit-spinetails frequent scrub and light woodland at high altitude.

[*Leptasthenura aegithaloides*, 15 km north-west of La Serena, IV Región, Chile. Photo: Gonzalo González C./ Science Adventure]

High along the timber-line in the Andes, the **White-chinned Thistletail** is normally hard to observe well and keeps to dense cover along the edges of montane woodland. The English name of "thistletail" refers to the extraordinary long, graduated and rather "decomposed" tail possessed by all eight members of the genus. These somewhat similar-looking species have allopatric distributions stretching down the Andes chain from Venezuela to Bolivia, and in the past some authors have suggested that they are all merely subspecies of one variable species.

M. Irestedt and colleagues, however, failed to produce any strong corroboration for this relationship.

Within the Furnariidae, some taxonomists have recognized three or four subfamilies as proposed monophyletic lineages. In cases in which the woodcreepers and the ovenbirds were considered to be two subfamilies, these groupings have been treated as tribes. Following this system, in the current linear sequence, the six genera from *Geositta* through to *Furnarius* represent the subfamily Furnariinae, whereas *Limnornis* to *Xenerpestes* make up the Synallaxinae. The position of the recently described genus *Acrobatornis* is unclear. Otherwise, the remaining 24 genera, from *Premnornis* to the end of the current sequence, constitute the Philydorinae, although the *Sclerurus* leaf-tossers and the monotypic genus *Lochmias* have been regarded by some authors as forming a separate subfamily, the Sclerurinae. The characters that unite the genera within each subfamily or tribe have not, however, been adequately outlined or demonstrated, and several recent classifications, including those of Sibley and B. L. Monroe, in 1990, and the American Ornithologists' Union, in 1998, have abandoned this level of classification. Furthermore, neither recent DNA-sequence data nor a phylogenetic analysis of nest-structure characters provided any firm evidence that these tribes represent monophyletic lineages. Although several major lineages of furnariids almost certainly do exist, manifested as well-separated deep branches of the phylogeny, it would seem unwise to accord them taxonomic rank at present. This is because the limits of those lineages are as yet uncertain, and many genera, such as *Geositta*, *Lochmias*, *Pygarrhichas* and *Clibanornis*, appear problematic.

The linear sequence of genera traditionally adopted by the majority of authors differs only in minor ways from C. E. Hellmayr's 1925 sequence. Until a modern, comprehensive, family-wide phylogeny is published that provides explicit hypotheses concerning basal taxa and intergeneric relationships, there is little reason for changing the historical sequence, even though it may be difficult or impossible in many cases to discover an explicit rationale for that sequence. As with all early classifications of taxa within bird families, the species composition and boundaries of each genus and the relationships among genera were undoubtedly inferred largely from non-quantitative assessments of similarities and differences in external phenotypic characters, namely morphology, plumage pattern and nest architecture. How accurately those assessments reflect phylogeny is not yet

known for certain. It is likely that the final verdict will reveal a blend of largely successful predictions based on phenotype, with most failures readily explainable with the benefit of hindsight, but also with some total surprises. Equally likely is that the predictive value of these assessments of phenotype will decay as one reaches farther back into furnariid history and into the deeper branches in the phylogeny. For example, K. Zyskowski and R. O. Prum's recent analysis of nest architecture produced a phylogenetic hypothesis that was largely consistent with the generic limits and sister relationships among genera as predicted by historical classifications, but provided lower resolution on the deeper branching patterns.

Because the nest-building behaviour is an inherited character, and because nest architecture differs so strongly among birds, nest structure has often provided data used in avian systematics. In the Furnariidae, the exceptional variation among genera prompted one of the earliest attempts at its use in classification, by H. von Ihering in 1915, and that early tradition continued through C. Vaurie's monograph, culminating in Zyskowski and Prum's analysis, in 1999. This last work is the only one to rely strictly on nest structure and to employ modern methodology. As emphasized by its authors and by many others, phylogenetic hypotheses based on single sets of characters have natural limitations. Nevertheless, nest structure in the Furnariidae provides strong support for some traditional groupings in the family, while also presenting some new hypotheses. The degree to which Zyskowski and Prum's use of the Dendrocolaptidae as an outgroup affected their results, given the likelihood that the woodcreepers are embedded within the furnariid tree, is uncertain.

Zyskowski and Prum's results point to the existence of several major clades in the family. Details of the various types of nest on which these are based are discussed in greater depth later (see Breeding). The largest clade consists of those genera that build domed nests, rather than being cavity-nesters, but including *Lochmias*, *Aphrastura* and *Leptasthenura*, members of which place domed nests in tunnels or holes. Within that group, the following relationships were supported: (1) a sister relationship between *Schizoeaca* and *Oreophylax*, which share *Sphagnum* moss nests; (2) a clade of marsh-nesters, *Limnornis*, *Limnocitites* and *Phleocryptes*, all of which construct an "awning" over the nest entrance; (3) a clade consisting of the Plain Softtail (*Thripophaga fusciceps*), *Siptornis*, *Premnoplex*, *Margarornis*, and eleven species of *Cranioleuca*, all of which have pensile nests

Like many ovenbirds, the *Itatiaia Spinetail* possesses a disproportionately long, graduated tail. The rectrices of this species are also pointed and rather disarrayed. The tail length of many furnariids is unusual for birds that do not use the tail for display purposes. The *Itatiaia Spinetail* has a highly restricted range, being confined to the highest mountains of south-east Brazil, a biogeographically unique distribution shared with no other Brazilian endemic. It occupies a monotypic genus the exact position of which within the family is the subject of some debate. Some authors consider the species best included with the thistletails (*Schizoeaca*), but most retain it in a separate genus.

[*Oreophylax moreirae*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

made of pliable plant matter; (4) a large group of taxa that use sticks as the major component of the nest; (5) within the stick-users, a group composed of *Schoeniophylax*, *Synallaxis*, *Gyalophylax* and *Certhiaxis* spinetails, which share the use of "thatch" over the nest-chamber; (6) a group that includes the previous genera and the cachalotes (*Pseudoseisura*), all of which restrict nest lining to the nest-chamber floor; and (7) the sister relationship of the monotypic genera *Anumbius* and *Coryphistera*, the Firewood-gatherer and the Lark-like Brushrunner, which share elaborate adornment of the roof of the nest-chamber.

Within the cavity-nesters, the analysis supported a close relationship among the Striped Woodhaunter (*Hyloctistes subulatus*), some *Automolus* foliage-gleaners, the Black-billed Treehunter (*Thripadectes melanorhynchus*) and the *Sclerurus* leaflossers, all of which build nests from rootlets and other fibrous material. Another clade consists of the hole-nesters that build woven cups of plant material; this includes the *Geositta* miners, the *Upucerthia* earthcreepers, the cinclodes, the *Furnarius* horneros, and a series of taxa from the "opposite" end of traditional linear sequences, namely the *Philydor*, *Anabazenops* and *Hylocryptus* foliage-gleaners, at least one *Automolus* foliage-gleaner, the four xenops, and one *Thripadectes* species, the Black-billed Treehunter.

These groupings, of course, leave many relationships unresolved, with polytomies in the phylogeny. They are consistent with continued retention of the monotypic genera *Eremobius*, *Chilia*, *Sylviorthorhynchus*, *Lochmias* and *Pygarrhichas*, but they call into question the monophyly of one genus, *Asthenes*, that seems dubiously monophyletic for other reasons. In addition, these results cast doubt on the monophyly of other genera which have seldom been questioned before, namely *Craniolaema*, *Thripadectes* and *Automolus*. Without additional information, especially genetic data, it is not possible to determine whether these genera are not monophyletic, or whether they are monophyletic and the nest structure is more "plastic" than assumed. Likewise, whether the groupings themselves reflect phylogeny or are artifacts of the analysis remains to be learned.

Regardless of these uncertainties, the analysis undertaken by Zyskowski and Prum represents major progress towards an understanding of the evolution of nest construction in the family Furnariidae, and provides a model for subsequent analyses. It of-

fers insights into the pathways of the evolution of nest architecture. For example, the analysis by those scientists leads to the hypothesis that nesting in cavities is the "primitive condition" in the Furnariidae, and that subsequent "loss" of this character is always accompanied by a compensating replacement character in terms of providing a covered or enclosed nest. Their phylogenetic hypothesis suggests that this has happened at least twice in the family, independently in *Furnarius* and in a lineage that includes those ovenbirds with domed nests made of plant material.

Use of other phenotypic characters in constructing phylogenetic hypotheses for relationships among the Furnariidae has been comparatively sparse. D. W. Rudge and R. J. Raikow used characters of the hind-limb musculature to analyse relationships within a few genera. Vocal characters have much potential for producing insights at the level of generic limits, yet only a few analytical studies have been published, examples of which are given later in this section. Although archived voice recordings now exist for a high percentage of species, a framework for character analysis and interpretation, following the model of M. L. and P. R. Isler and B. M. Whitney for the *Thamnophilidae*, has yet to be established. Similarly, behavioural features, such as displays and postures, have the potential to yield insights into relationships, but the employment of these aspects is hindered by a near absence of data. Even so, characters such as the wing-flapping display of the genus *Cinclodes* and the strutting walk of *Furnarius*, each of which seems diagnostic for the respective genus, provide cause for optimism that behavioural data can further an understanding of the relationships among the members of the family. In addition, analyses of plumage characters, using modern scientific methods, should prove fruitful, despite the reputation of such parameters as being "old-fashioned". Although plumage characters undoubtedly played a major role in defining genera in the Furnariidae, the eclectic and non-quantitative way in which they have been used leaves much room for improvement and, perhaps, some surprises. Furthermore, an analysis using modern phylogenetic methods may produce insights into the deeper patterns and pathways of plumage evolution in the family.

The linear sequence in the Furnariidae traditionally begins with the eleven miners in the genus *Geositta*. As noted above, the syrinx of these species possesses large horns, unlike that of any other ovenbird genus, so far as is known, but similar to that of the *Dendrocolaptidae*. This character sets *Geositta* apart from

These striking **Chotoy Spinetails**, although similar to the *Synallaxis* spinetails, are considered to belong in a monotypic genus on the basis of striking differences in their vocalizations. This pair neatly demonstrates the nearly complete lack of sexual dichromatism found throughout the ovenbird family, although the males of some species have been noted to be subtly brighter than the females. Likewise, there is very little evidence of strong size dimorphism in the Furnariidae; where data sets exist, they suggest that males are just slightly bigger than females. This being so, it is tempting to speculate that the bird on the left may be the male of this pair. Generally, ovenbirds appear to live in pairs throughout the year, and perhaps many species pair for life. Bird species that exhibit little sexual dichromatism or dimorphism usually have equal roles during the breeding cycle and have adopted strict monogamy.

This is likely to be the case throughout the ovenbird family, although, for most species, the information has yet to be collected to confirm these suppositions. The Chotoy Spinetail is distinctive because its plumage includes a yellow throat patch. In most furnariids, brown is the basic overall plumage colour. The few exceptions include several species or genera that stray into black, white and grey colorations, but in general few taxa deviate from this rule, and the possession of spectral colours is even more unusual among the members of this family.

Currently comprising 33 species, the Synallaxis spinetails form the largest genus within the ovenbird family. They are distributed throughout South America except the extreme south and the highest elevations. Up to four species may occur at some sites.

Although some members of the genus, such as the **Pale-breasted Spinetail**, are widespread, many have very restricted ranges. Two such species are **Spix's Spinetail** and the **Rufous-capped Spinetail**, both found within relatively small areas in south-east Brazil, Uruguay and north-east Argentina, where their distributions overlap.

Because of this tendency for restricted geographical ranges, one new species has been described since 1970 and undoubtedly others still await discovery. Plumage features characteristic of the genus, and well illustrated by Spix's Spinetail, include a long, graduated tail, and crown and shoulder patches of a matching colour, with a partially concealed throat patch occasionally present. Although the members of this genus tend to have similar plumages, and can be confusingly difficult to distinguish from one another, all frequently utter diagnostic contact calls and songs that are useful aids to field identification. Spinetails often sing from exposed perches, but spend the rest of the time skulking in pairs in dense vegetation close to the ground.

Most Synallaxis species, as typified by the Pale-breasted and Spix's Spinetails, are found in dense vegetation in open areas or along the borders of forested areas, but a few, including the Rufous-capped Spinetail, are confined to the thick undergrowth of humid forest.

The rather drab, bicoloured **Yellow-chinned Spinetail**, widespread in eastern South America, is associated with wetland habitats. Active and conspicuous, it is often found feeding in the open along wetland margins or foraging on mats of floating vegetation. It is not known whether this species also takes prey items directly from the water. Its sole congener has a rather restricted range, occurring only in grassy and shrubby riparian habitat, especially on islands and oxbow lake margins, along the major rivers in the Amazon Basin. The two species occur alongside each other at some sites. The exaggerated thickness of the legs of many ovenbirds, noted by numerous field observers, is apparent in this species.

other genera, which may indicate that it is, indeed, basal within the family. The miners are also the only members of the family with an emarginate, or notched, tail, and some miners have the most conspicuous tail patterns amongst the Furnariidae. All are short-tailed terrestrial birds of open habitats, with flight abilities much greater than those of most other ovenbirds. Many or perhaps all miners also have flight songs, in contrast to other genera. Apart from the *Cinclodes* species, the miners are the only members of the family that habitually forage on open ground and generally avoid vegetation. Their aerial songs, strong flight, and conspicuous wing and tail patterns are all symptomatic of their being essentially open-country birds. Although some other furnariids are found in relatively desolate habitats, those other species, in genera such as *Upucerthia* and *Asthenes*, prefer some cover, even if only sparse clumps of grass, cacti, bushes or rocks (see Habitat). The bills of *Geositta* miners vary from short and straight to long, thick and curved; this variation is presumably associated with increased digging and probing foraging manoeuvres by the longer, more curve-billed species, but informative data are lacking.

Following the miners, the nine earthcreepers in the genus *Upucerthia* share with *Geositta* similarities in nest-site, using tunnels excavated in banks, and nest structure, building simple platforms of grasses and other plant matter, as well in some plumage features, such as wingbands. The *Upucerthia* earthcreepers are sneaky, long-tailed terrestrial species of arid, often rocky scrub, where they often carry the tail in a cocked position. The two monotypic genera *Eremobius* and *Chilia*, because of their rather unusual nests, as well as their distinctive plumage features, do not fit neatly into the existing sequence. In fact, the domed stick nest of *Eremobius* is more like those of many canasteros (*Asthenes*), spinetails (*Synallaxis*) and thornbirds (*Phacellodomus*) than like those of the mostly tunnel-nesting *Upucerthia* that it resembles most closely in general morphology. The reason for its historical placement following *Upucerthia* is presumably its general similarity to the Bolivian (*Upucerthia harterti*) and Chaco Earthcreepers (*Upucerthia certhioides*), which in turn differ in several ways from others of that genus. Regardless of nest differences, some ornithologists suspect that *Upucerthia*, as currently defined, may be paraphyletic with respect to *Eremobius*;

they believe that some species in *Upucerthia* are possibly more closely related to *Eremobius* than they are to other *Upucerthia*, particularly if, as in the existing classification, the latter includes the taxa *harterti* and *certhioides*. These last two have at times been treated in a separate genus *Ochetorhynchus*, although this is not correct in terms of nomenclature, since the type species of that genus is *ruficaudus*.

The next major genus is *Cinclodes*, a group of 13 species widely distributed in the cold regions of southern South America. They are terrestrial foragers that are frequently associated with water-edge habitats. Many, and probably all, of them have distinctive wing-flapping displays during which they sing from a perch and slowly flap their wings, exposing contrastingly coloured wingbands. Vaguely resembling thrushes (*Turdidae*) in appearance, the cinclodes share with most of the previous genera the habit of excavating tunnels for their nests, which are usually simple cups or platforms of plant matter. They show a greater tendency also to use existing crevices and nooks for nest-sites. In terms of flight abilities, they are second only perhaps to the *Geositta* miners, and superior to them in their record of colonizing oceanic islands. All these genera share similar biogeography and habitat patterns: they are characteristic of some of the most hostile environments in South America, from frigid alpine slopes to bitterly cold, wind-swept barren lands, to rainless deserts.

Lending their name to the family as a whole are the six species of hornero, sometimes referred to as "ovenbird", in the genus *Furnarius*. The "adobe oven" nests of most horneros are remarkable structures. Their resemblance to the clay ovens that at one time were in widespread use in Latin America gives these species their scientific, English and Spanish names. Long-billed, short-tailed, high-stepping walkers that strut with the head held somewhat back and the chest thrust forward, they forage primarily on open ground or mud. The horneros occupy habitats lacking extensive dense vegetation; even when within forested regions, they are found at margins and edges with open ground. They are renowned for their raucous duets. One species, the Wing-banded Hornero (*Furnarius figulus*), does not construct an adobe-style oven nest, and is therefore likely to be the basal member of the genus, even though this is not reflected in traditional taxonomic sequences.

**Pallid Spinetails** are rather conspicuous, active and acrobatic residents of montane forest in south-east Brazil. Their agile foraging technique is a typical trait of the genus *Cranioleuca*.

These spinetails are well adapted for climbing along branches and up trunks. The stiffened tips of the feathers of the short, double-pointed tail are used as a prop to provide support when climbing vertical surfaces, an aid that is also available to and used by some other forest-dwelling genera of the *Furnariidae*.

The members of the genus as a whole are found in most forest types of the Neotropics, from the lowlands to the tree-line of the high mountains. Many species build large oval nests, mostly of moss, which hang conspicuously from drooping branches. *Cranioleuca spinetail* are often conspicuous components of the mixed-species bird flocks that sweep through Neotropical forests and so confuse and delight first-time visitors to the region.

The only one found outside forest or woodland is the **Sulphur-throated Spinetail**, which is, instead, a secretive marsh-dweller inhabiting reedbeds throughout a relatively small range in northern Argentina, Uruguay and southern Brazil. The most recently discovered member the genus, the *Bolivian Spinetail* (*Cranioleuca henricae*), was described as recently as 1997. It was immediately categorized as globally threatened, primarily because of the severe and continuing habitat degradation that was evident over its small range.

[Above: *Cranioleuca pallida*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Below: *Cranioleuca sulphurifera*, Salado's Depression, Buenos Aires, Argentina. Photo: Yves Bilat]

The long-tailed, rather drab **Dusky-tailed Canastero** often sings from exposed perches, and this is one of the few times when it can be easily observed. Ordinarily, it is a shy, terrestrial species that skulks in the dense thickets of the Chilean matorral. The reclusive behaviour of the canasteros can make identification of the 22 recognized species a difficult challenge in the field, as it is difficult to see the distinguishing plumage characteristics. Canasteros are found in fairly open habitats with scrub, grass and rocky outcrops throughout Andean and southern South America. The vernacular name "canastero" means basket-maker, and refers to the interwoven stick nests that these birds build low in bushes, trees and rock outcrops.

[*Asthenes humicola humicola*, Copiapó, Atacama, Chile.  
Photo: Adolf de Sostoa & Xavier Ferrer]

The next group consists of four genera, each containing only one or two species, and none having any obvious close relatives. The marsh-nesting *Limnornis* and *Limnortites* have been combined by some authors in *Limnornis*, but it is not certain that they are sister taxa. The two differ strongly in tail structure, as well as in the materials used for nest-building, and in the colour of their eggs. The blue-green eggs of *Phleocryptes* are unusual among furnariids, but the nest architecture of this species is similar to that of the previous two genera, although its plumage suggests a possible relationship to the fourth genus, *Aphrastura*. The two species in *Aphrastura* provide an amazing example of long-distance over-ocean colonization either by the Thorn-tailed Rayadito (*Aphrastura spinicauda*), followed by subsequent divergence leading to the Masafuera Rayadito (*Aphrastura masafuerae*), or by an ancestor common to both (see also Movements). It is also worth mentioning here that the genus *Pygarrhichas* may belong next to *Aphrastura*, as suggested by superficial plumage similarities and biogeography, rather than near *Xenops* at the end of the sequence, where it has traditionally been placed. On the other hand, the monotypic genus *Sylviorthorhynchus* has usually also been placed near the above genera, but without any explicit rationale. It is considered better to move it to a position next to the *Schizoeaca* thistletails, on the hypothesis that a general similarity between the two in morphology, and their similar preferences for cool, moist habitat, may well reflect phylogenetic relationships.

*Leptasthenura* encompasses a group of ten long-tailed, active, highly arboreal, very acrobatic species with the smallest bills in the Furnariidae. These are the tit-spinetails, the general behaviour and morphology of which have suggested to many that they are convergent with the long-tailed tits of the Old World genus *Aegithalos*. Nest-sites and nest structure are more variable in this genus than in any other in the family (see Breeding). Further, the use of vocalizations in an attempt to determine relationships within the genus is hindered by the seemingly complex repertoire of these species. The tit-spinetails appear to have no obvious close relatives in the family. Their general size and shape have led to their regular placement near or next to the thistletail and spinetail genera that follow. It has been suggested that the monotypic genus *Spartonoica* might be related to *Leptasthenura* or *Asthenes*, although some authors have merged it with *Synallaxis*.

The eight species of *Schizoeaca* thistletails form a super-species, the distribution of which defines the humid timber-line ecotone of the Andes. The long, somewhat "disintegrated" tail accounts for the English name. All eight are sufficiently similar to one another that some authors have combined them in a single species. If any vocal differences do exist among them, they have not been adequately documented. The monotypic genus *Oreophylax* of montane south-east Brazil has been included in *Schizoeaca* by some taxonomists; in addition to morphological similarities, the nests and habitat of the two are similar. If this sister relationship is correct, then it is indeed remarkable biogeographically. Although the mountains of south-eastern Brazil share some avifaunal affinities with the Andes, these are generally restricted to genera that occur at low elevations in the Andes or even in the lowlands of southern South America. In contrast, *Schizoeaca* is confined to the higher elevations and seems an unlikely candidate for having a sister-taxon in south-east Brazil when so many other, more broadly distributed Andean bird genera have no representative there. Among the Furnariidae, for example, *Premnornis*, *Premnoplex*, *Margarornis*, *Pseudocolaptes* and *Thripadectes* are reasonably widespread in the Andes, and most of them also extend into Central America, yet none is represented in south-east Brazil. *Schizoeaca* and *Oreophylax* share a similar throat-patch configuration with the *Asthenes* canasteros, and many taxonomic lists place these genera in adjacent positions. The problem with that arrangement, however, is that those members of *Asthenes* that build stick nests resemble the smaller *Phacellodomus* thornbirds in many ways, and these two genera are therefore listed next to each other in other linear sequences. Genetic studies are needed in order to resolve this issue; it seems likely that the genus *Asthenes* is polyphyletic.

Next in the current sequence are the small furnariids, generally known as spinetails, in the seven genera *Schoeniophylax*, *Synallaxis*, *Siptornopsis*, *Gyalophylax*, *Hellmayrea*, *Craniola*

and *Certhiaxis*. Some of these species possess a peculiar musty odour, but it is unknown just how many do, and any attempt to quantify this odour in terms of taxon distribution is difficult (see Morphological Aspects). The monotypic genus *Schoeniophylax* has sometimes been included within *Synallaxis*, but its voice is so utterly different from that of any *Synallaxis* spinetail that its retention as a separate genus is deemed warranted. It has to be remembered, of course, that genetic data may eventually indicate that this arrangement would make *Synallaxis* paraphyletic. With a total of 33 species, *Synallaxis* is the largest genus in the family. The possession of crown and shoulder areas that match in colour, and contrast with the rest of the plumage, is a frequent theme in the plumage pattern of its members, and many species have a partially concealed throat patch that can be made more conspicuous during displays (see General Habits). Despite its size, and although distinct lineages, based primarily on voice, can be identified within it, the genus is suspected of being monophyletic with the single exception of the Necklaced Spinetail (*Synallaxis stictothorax*). Three species, the Ochre-cheeked (*Synallaxis scutata*), White-whiskered (*Synallaxis candei*) and Hoary-throated Spinetails (*Synallaxis kollari*), were formerly placed in a separate genus *Poecilurus*, on the basis mainly of plumage patterns, but the three do not differ from other *Synallaxis* in any diagnosable way. *Synallaxis* spinetails are long-tailed, sneaky birds that characteristically forage in pairs low in dense vegetation. The partners keep in nearly constant contact by means of short, distinctive vocalizations, which are considered to be "songs" by some ornithologists and "calls" by others (see Voice).

With its fairly uniform plumage and thick, slightly decurved bill, the **Greater Thornbird** is typical of its genus. Other common features include stiffened crown feathers, and a moderately long, graduated tail that lacks the stiffened shafts found in many other furnariid genera. Thornbirds build large stick nests that rest on or hang conspicuously from tree branches. The presence of such nests, together with the birds' often explosive songs, provides the easiest means of detecting these normally retiring members of the family. The Greater Thornbird inhabits riparian undergrowth and scrub in south-central South American wetlands.

[*Phacellodomus ruber*, Rio Negro, Pantanal, Mato Grosso, Brazil. Photo: Edson Endrigo]

Following this large genus are three monotypic genera that may or may not warrant that status. *Siptornopsis* is closer in voice and behaviour to *Craniroleuca* than to *Synallaxis* and may eventually be shown to be embedded within the former. In addition, *Synallaxis* is almost certainly paraphyletic with respect to *Siptornopsis*. As many authors have pointed out, the Necklaced Spinetail is almost certainly just a low-elevation, undersized version of the Great Spinetail (*Siptornopsis hypochondriaca*). It may be better to include *Gyalophylax* within *Synallaxis*, especially since Whitney and J. F. Pacheco have pointed out that its voice has a suspicious resemblance to that of the Cinereous-breasted Spinetail (*Synallaxis hypospodia*). The genus *Hellmayrea* was included within *Synallaxis* until the analyses by M. Braun and T. A. Parker indicated that it is closer to, if not synonymous with, *Craniroleuca*. The latter study represents one of the earliest applications of knowledge of voice and behaviour, combined with molecular techniques, in constructing phylogenetic hypotheses.

In contrast to the three preceding genera, the polytypic genus *Craniroleuca* consists of 20 species of spinetail. These appear to represent at least four lineages, the degree of interrelatedness of which is unknown. All species have reddish-chestnut upperwing-coverts, remarkably homogeneous in hue. All but three have a contrasting crown coloration, usually also reddish-chestnut, and two of the three lacking this contrast, namely the Rusty-backed Spinetail (*Craniroleuca vulpina*) and Parker's Spinetail (*Craniroleuca vulpecula*), have the crown reddish-chestnut and of the same tone as the back. The members of this genus, more active, acrobatic and arboreal than *Synallaxis*, are also more characteristic of truly forested habitats, and are typical members of mixed-species flocks. Almost every type of wooded habitat in South America has a species of *Craniroleuca*, with the conspicuous exception of most *terra firme* forest in Amazonia.

The genus *Certhiaxis* consists of two species of spinetail closely associated with tropical marshes and water-edge habitats. Vaurie merged this genus with *Craniroleuca*, but, in view of the differences between the two genera in nest structure, foraging stratum, voice and general behaviour, it is not even certain that they are each other's closest relatives. Although the two *Certhiaxis* species are extremely similar in appearance, they differ dramatically in distribution and abundance. The Yellow-chinned Spinetail (*Certhiaxis cinnamomeus*) is common in many types of water-edge habitat over a broad geographical range; in contrast, the Red-and-white Spinetail (*Certhiaxis mustelinus*) is

an uncommon, local species known from just a few localities along the River Amazon and a few major tributaries.

The four softtails in the genus *Thripophaga* form a heterogeneous group, the monophyly of which has been questioned by many authors. Nevertheless, all four, in addition to exhibiting similarities in tail structure and head pattern, appear to have an affinity for habitats with dense vine tangles. Further, each one has a somewhat peculiar, patchy distribution. For example, the Plain Softtail, the only member of the genus *Thripophaga* that is not globally threatened (see Status and Conservation), has populations scattered in south-western Amazonia and also in drier woodlands south of Amazonia, an odd biogeographical pattern. The Russet-mantled Softtail (*Thripophaga berlepschi*) is known only from a few localities near the timber-line in the Andes of northern Peru, whereas the Orinoco Softtail (*Thripophaga cherriei*) is known from a single site in southern Venezuela. The Striated Softtail (*Thripophaga macroura*) is confined to just a few localities in south-eastern Brazil, but the patchiness of its occurrence may reflect simply the scattered nature of suitable tall forest in that badly deforested region. If *Thripophaga* is indeed discovered to be monophyletic, the odd distributions of its component species presumably constitute a relict distributional pattern that may, in turn, reflect an ancient, basal position in its branch of the Furnariidae.

Twenty-two canasteros make up the genus *Asthenes*. These are typically shy birds of habitats dominated by shrubs, grass and rocks, and many of the species carry the tail cocked. They have been considered a monophyletic group largely because of a shared plumage feature, all having a patch of contrasting colour on the throat or chin, and a similar general morphology, involving small size and a long, graduated tail. Such mutual features notwithstanding, at least three distinct lineages can be identified within the genus, and these may not be each other's closest relatives. A group of canasteros that construct nests mainly of sticks is found throughout the drier, lightly wooded or brushy habitats of southern South America. This group, the members of which lack stripes but have a contrasting tail pattern, is suspiciously similar to the smaller *Phacellodomus* thornbirds in plumage and, to a lesser degree, in nest structure and general behaviour; in fact, if one disregards the throat patch, the Short-billed Canastero (*Asthenes baeri*) and the Creamy-breasted Canastero (*Asthenes dorbignyi*) are strikingly similar in plumage and size to the Little Thornbird (*Phacellodomus sibilatrix*) and the Streak-fronted

The small, dark **Spotted Barbtail** is a rather unobtrusive inhabitant of montane forest in the Andes. It spends much of its time in quietly creeping up trunks and along branches, and can be difficult to detect. Climbing in this manner to search for food is a common foraging technique in many genera of ovenbirds. Adaptations developed to aid climbing include stiffened tail-feather shafts and, as shown by the Spotted Barbtail, stiff protruding "spines" at the tips of the rectrices, as well as strong legs and toes. Such modifications allow a level of agility that enables some furnariids to reach prey in almost every conceivable hiding place.

[*Premnoplex brunescens*

Thornbird (*Phacellodomus striaticeps*), respectively. Perhaps the stick-nesting canasteros are more closely related to *Phacellodomus* than they are to other *Asthenes*. Another group of canasteros, in this case building nests primarily of grass and having strongly striped plumage, is found in humid, usually grassy habitats in the same general region. At least one species of *Asthenes* is present in almost every open habitat in Andean and southern South America, from lush, mist-drenched timber-line brush to desolate rocky slopes.

The seven species of thornbird in the genus *Phacellodomus* are considered to form a monophyletic group partly because of a similarity in their nest types. All construct a large stick nest that

typically becomes pensile by virtue of its own weight, which causes the supporting branch to bend downwards. Otherwise, they all have a rather thick, slightly decurved bill, stiffened feathers on the forehead, and a graduated tail with broad, rounded rectrices that lack stiffened shafts. The name "thornbird" may suggest that these are inhabitants of arid scrub, but three species in the genus are partially to strongly associated with marshes or water edge.

Following *Phacellodomus* is the monotypic *Clibanornis*, which is placed in this position because it has been considered by some to be more similar to *Phacellodomus* than to any other genus. Nothing in its habitat, voice or foraging behaviour, however, seems to suggest a relationship to the thornbirds. Its nest,

The beautifully marked, richly coloured **Fulvous-dotted Treerunner** is an inhabitant of the Andean forest of Colombia and Ecuador. The exposed shafts of the tail-feather tips are the clue to its primary foraging method, that of climbing trunks and branches. Even a casual observer, surveying the full spectrum of ovenbirds, could not fail to comment on the fact that brown is predominant in the plumage of the majority of the family. Despite this apparent constraint, some, such as the Fulvous-dotted Treerunner, have such rich browns that they are truly colourful. Further, pale feathers with contrasting dark margins, as on the throat of this species, create stunning patterns in some furnariids.

[*Margarornis stellatus*,  
north-west Ecuador.  
Photo: Doug Wechsler/  
VIREO]

Large, rather striking and placed in a monotypic genus, the **Point-tailed Palmcreeper** is a specialist species restricted to palm groves in Amazonia. It is arboreal and unobtrusive, and it feeds by searching palm fronds and their bases. It favours moriche palms (*Mauritia*), which grow only in small groves often separated by great distances, suggesting that the palmcreeper is capable, when required, of dispersing widely in order to find suitable habitat. This degree of specialization represents an extreme in the tendency of many Neotropical birds to show narrow habitat use, although only a few are restricted to palms. Interestingly, another ovenbird, the *Araucaria* Tit-spinetail (*Leptasthenura setaria*), exhibits an equally strict requirement for a particular plant species, albeit a more widespread component of the flora where it occurs. Specialization in habitats with unusual vegetation structure, however, is not unusual in the family as a whole, a fact that is perhaps reflected by the mystifyingly small ranges of certain species. These can be found in some places but often appear not to be present in apparently suitable habitat nearby. In these cases, a species' presence or absence may be dictated by fine-scale habitat parameters that are not readily apparent to the human observer. Members of the *Furnariidae* have successfully occupied every available terrestrial habitat in South America, and two species are even restricted to rocky, intertidal marine habitats, a feat unparalleled among passerine birds. Ovenbirds are prominent components of all bird communities on the continent, and in the low-diversity communities of harsh environments, they often make up as much as 25% of all the avian species present.

One of few furnariids that penetrate as far north as Mexico is the **Scaly-throated Foliage-gleaner**.

As this attractive, small, arboreal ovenbird of montane forest in Middle America and the northern Andes often feeds low down and in the extremities of trees, it is usually fairly easy to see. Of the other two members of the genus, one occurs in Andean montane forest from Venezuela to Bolivia, and the other is an Atlantic Forest endemic. The widespread Scaly-throated Foliage-gleaner may consist of more than one species. Species limits within the family are constantly being challenged as knowledge of geographical variation and vocal differences increases.

[*Anabacerthia variegaticeps*  
*variegaticeps*,

Quintana Roo, Mexico.  
Photo: Patricio Robles Gil]

A resident of humid lowland forest in Central and South America, the long-billed and drab **Striped Woodhaunter** is in some ways reminiscent of a small woodcreeper (*Dendrocolaptidae*).

Striped Woodhaunters forage by gleaning and burrowing for invertebrates and small vertebrates (lizards and frogs) in debris and dead leaves and among epiphytes. There are two discrete populations of this ovenbird, one in Central America and southwards, east of the Andes, to western Ecuador, and the other occurring east of the Andes. These two populations, which differ in plumage and have markedly different vocalizations, probably represent two species.

which would certainly provide clues as to its proper relationships, has yet to be discovered. The next two genera in the sequence are the similarly monotypic *Anumbius* and *Coryphistera*. Similarities in nest structure, as identified by Zyskowski and Prum, support the notion that these are each other's closest relatives, but, beyond that, their relationships are obscure. The plumage pattern of each is unusual. The Lark-like Brushrunner is a peculiar bird not only in plumage pattern, but also in its degree of sociality. It is perhaps the only member of the family that characteristically forms single-species flocks. During the breeding season, these are small enough, usually of five to seven individuals, that kinship among flock-members is a possibility, and this species is therefore perhaps the most likely of the Furnariidae to have an unusual social system. Further contributing to the oddity of this species is the fact that its flocks typically travel by running along the ground, which is unusual for terrestrial, gregarious birds other than Galliformes; many gregarious birds of open country feed together in flocks on the ground, but, when they move, flight is the more typical means. The Firewood-gatherer is almost as peculiar. In plumage and shape it recalls an oversized pipit (*Anthus*), and the conspicuous white markings in the outer rectrices are very unusual among the Furnariidae.

The next set of genera constitutes a collection of small, highly arboreal, and acrobatic to scansorial species that may or may not form a monophyletic group. The Spectacled Prickletail, in the monotypic genus *Siptornis*, is a poorly known species with no obvious close relatives. Although having no unique plumage or morphological features, it does not fit neatly into or even near any other genus. The next three genera, *Metopothrix*, *Xenerpestes* and *Acrobatornis*, represent perhaps the most unusual species in the family in terms of coloration and distribution (see Morphological Aspects), and Whitney and co-workers suspect that, for these and other reasons, they are closely related. Next come the three species of barbtail in the genera *Premnornis* and *Premnoplex*. These are notorious sneaks inhabiting montane forest, and their true abundance is often revealed only by mist-netting studies. Adding to its reputation as a "ghost", the Rusty-winged Barbtail has possibly the largest geographical range of any Neotropical species for which published descriptions of vocalizations are essentially lacking. A fourth barbtail, the Roraiman Barbtail (*Roraimia adusta*), endemic to the tepui re-

gion of southern Venezuela and adjacent Brazil and Guyana, and placed in a monotypic genus, may be more closely related to the *Margarornis* treerunners than to the three *Premnoplex* and *Premnornis* barbtails. The four species of treerunner are perhaps the most "professionally" scansorial species in the family. The stiffened tail with bare, slightly bent shaft tips ranks with that of

*Pygarrhichas* as the most specialized of any furnariid tail for climbing, and the central rectrices appear more drastically modified than are those of some woodcreepers in the genus *Dendrocincla*. Rudge and Raikow found that *Premnornis*, *Premnoplex*, *Roraimia* and *Margarornis* share similar adaptations for climbing in the hind-limb musculature.

Combined in the genus *Pseudoseisura*, the four cachalotes are among the largest species in the family. Although superficially resembling jays (Corvidae) in size, shape and behaviour, they betray their ovenbird bloodlines by their raucous, staccato voices and their huge stick nests, some of which can support the weight of a human. The cachalotes have no obvious close relatives. In their "demeanour", plumage and loud duets they are vaguely reminiscent of the *Furnarius* horneros, but their nests differ dramatically. R. S. Ridgely's suggestion that they are "exaggerated" thornbirds has as much merit as any, especially since the nests of the two genera are somewhat similar.

Of all furnariids, the two tuftedcheeks comprising the genus *Pseudocolaptes* are the species most highly specialized on searching tank bromeliads and other epiphytic vegetation. Preliminary observations suggest that only one parent attends the nest, a phenomenon that may be unique within the family. As quantified by S. Sillett and co-workers, *Pseudocolaptes* exhibits marked sexual dimorphism in bill length, again unlike any other furnariid (see Morphological Aspects). The fact that the female is the sex with the longer and straighter bill is also very unusual, and perhaps unique, among the Passeriformes, but parallels the direction of sexual dimorphism shown by many woodpeckers (Picidae) and hummingbirds. Likewise, the Point-tailed Palmcreeper in the monotypic genus *Berlepschia* has no obvious close relatives, but its general morphology has led to its placement next to *Pseudocolaptes* in traditional sequences. In its notorious degree of specialization on palm trees (see Habitat) it is perhaps unmatched by any other Neotropical bird species.

The Striped Woodhaunter occupies a genus, *Hylocistis*, currently treated as monotypic only because data sufficient for splitting it into two species-level taxa have not been published. It is typically placed near the previous two genera on account of similarities in bill shape, which is long and pointed, and was included by Vaurie in what is generally considered an unacceptably broad genus *Philydor*. Its true relationships, however, are uncertain. In shape and plumage, Amazonian populations of *Hylocistis* look more like *Xiphorhynchus* woodcreepers than like other ovenbirds, although they bear at least a superficial resemblance to the furnariid genera *Cichlocolaptes*, *Ancistrops* and *Premnornis*.

The ten genera *Anabacerthia*, *Syndactyla*, *Simoxenops*, *Ancistrops*, *Philydor*, *Anabazenops*, *Cichlocolaptes*, *Thripadectes*, *Automolus* and *Hylodyptes*, mostly called "foliage-gleaners", may indeed form a monophyletic group. They have several features in common. These include habitat preferences, mostly humid or semi-humid forest, and foraging behaviour, involving searching with side-to-side movements along mostly horizontal branches, and to varying degrees searching dead leaves suspended above the ground (see Food and Feeding). In addition, they choose similar nest-sites, those species for which relevant information is available using cavities and tunnels.

Although none of these features is sufficient evidence for monophyly, stronger evidence comes from the intermediacy of some of the species, and from the fact that a number of them have been, or are likely soon to be, switched from one genus to another. For example, the Dusky-cheeked Foliage-gleaner (*Anabazenops dorsalis*), long considered a member of *Automolus*, has been demonstrated convincingly by A. Kratter and Parker to be the sister-species to the White-collared Foliage-gleaner (*Anabazenops fuscus*). The Russet-mantled Foliage-gleaner (*Philydor dimidiatum*) was at one time placed in the genus *Syndactyla*, and in this context the history of the taxon *mirandae*, described from Goiás, in Brazil, is of interest. Formerly treated as a race of the Buff-browed Foliage-gleaner (*Syndactyla rufosuperciliata*), *mirandae* was later believed to be referable to the Russet-mantled Foliage-gleaner, being probably a synonym of the latter's subspecies *baeri*. When the results of a recent study by M. B. Robbins and K. J. Zimmer, based on vocalizations and other characters, are published, it seems likely that the Russet-mantled Fo-

**The Black-capped Foliage-gleaner** is a rather uniform bird with a well-marked facial pattern, a plumage typical of the genus *Philydor*. These foliage-gleaners inhabit humid forest throughout tropical and subtropical South America. Most, like this species, feed quietly in the forest canopy and subcanopy. All forage actively and are skilful acrobats, enabling them to reach many food resources that are unavailable to other, less agile bird species. In the forests in which they occur, most members of this genus are almost always found in mixed-species feeding flocks of passerines. It has been noted that, whereas many bird species will sing occasionally after a peak of activity at dawn, foliage-gleaners in the genus *Philydor* rarely sing after dawn. This trait is shared by other species of furnariid and also by the woodcreepers (*Dendrocolaptidae*), and is perhaps yet more evidence of a close link between the foliage-gleaner lineage in the ovenbirds and the woodcreepers. Some classifications treat the foliage-gleaners, currently split into some ten genera in total, as representing only three genera. The different genera certainly share common traits such as habitat preference, foraging techniques and the use of cavities for nesting. In addition, generic separation has been rather fluid in the past, with some species being assigned first to one genus and then subsequently to another. Clearly, more research is required in order to clarify the phylogeny of this group of birds.

[*Philydor atricapillus*, Ubatuba, São Paulo, Brazil. Photo: Edson Endrigo]

The large, boldly marked and stout-billed **Flammulated Treehunter**

is a furtive denizen of the montane forest of the Andes from Venezuela to Peru, with an outlying population in the Santa Marta mountains of northern Colombia.

It favours dense undergrowth, including bamboo, and can as a consequence be hard to observe. Strong associations with bamboo thickets are not uncommon in the Furnariidae, some species of which are even totally restricted to this habitat. The seven *Thripadectes* treehunters are rather similar and are scattered mainly throughout the Andes, although one species occurs in the mountains of Central America. They nest in burrows usually dug into earth banks.

VIREO]

liage-gleaner will be returned to the genus *Syndactyla*; it certainly appears closer to that genus than to other *Philydor* species in terms of its voice and its upturned lower mandible. Similarly, the Rufous-necked Foliage-gleaner (*Syndactyla ruficollis*) had been placed in the genus *Automolus* until Parker pointed out that its vocalizations indicated that it belonged in *Syndactyla*. The Chestnut-capped Foliage-gleaner (*Hylocryptus rectirostris*), too, was for many decades considered to be an *Automolus*, despite its strikingly different plumage. Several authors have wondered whether the White-throated Foliage-gleaner (*Automolus ro-raimae*) should be placed in *Philydor*; in fact, it was originally described in that genus, and, even after it was moved to its present genus, the juvenile of this foliage-gleaner was long thought to represent a distinct species, "*Philydor hylobius*". The suspicious similarity in plumage and size between the Lineated Foliage-gleaner (*Syndactyla subalaris*) and the Striped Treehunter (*Thripadectes holostictus*) clouds the boundaries between those two genera, which are seemingly separated mainly by bill shape, perhaps the least reliable avian phenotypic character for predicting phylogenetic relationships. Likewise, the Chestnut-winged Hookbill, the sole member of the genus *Ancistrops*, appears to be excluded from the genus *Philydor* only by bill shape. Vaurie attempted to solve these problems by merging the ten genera into three, *Philydor*, *Automolus* and *Thripadectes*, but the reaction of most ornithologists familiar with this group is that this arrangement does no more than reduce the number of "problem" taxa and that, in order to eliminate all such problems, the merger of all ten genera into a single genus would be the only solution. This, however, would result in a genus that most modern systematists would regard as being unacceptably heterogeneous.

The next genus in the current sequence, *Sclerurus*, is sometimes placed at the very end of the family. This position could well be considered a "better" one in that it emphasizes that the leaf-tossers are not clearly close to any other genus with the possible exception of the monotypic *Lochmias*, which is placed next to *Sclerurus* in most treatments. The stiffened feather shafts of the tail of the leaf-tossers are unusual among ground-foraging birds. Leaf-tossers have a conspicuously long, thin, rather straight bill and a broad tail. Using the bill, they flick aside leaf litter, rather than "tossing" it. Their songs, consisting of mainly clear,

whistled notes, are unlike any others within the Furnariidae. *Sclerurus* is almost certainly monophyletic, but it appears to consist of two or three lineages. All six leaf-tossers are birds of humid lowland or lower montane tropical or subtropical forest. Traditional sequences group *Lochmias* with *Sclerurus* because the two share stiffened tail feathers and terrestrial foraging habits, both nest in tunnels, and they are similar in general shape. The nests themselves, however, differ substantially, being a mere pad in the case of *Sclerurus* but a domed mass of plant material in *Lochmias*. Indeed, of the many ovenbirds that nest in holes in banks, *Lochmias* is the only one that constructs such a ball of plant matter in which to lay its eggs.

Making up the final set of genera in the Furnariidae are species that are specialized branch-foragers or climbers, and that nest in tree cavities. They are almost certainly not a natural group, as has already been discussed above with regard to the monotypic genus *Pygarrhichas*. *Megaxenops*, also monotypic, is placed in this group because its upturned lower mandible is thought by some to be reminiscent of an oversized *Xenops* bill, but nothing else in its biology suggests a relationship with *Xenops*. A third monotypic genus, *Heliobletus*, shares some plumage features with the larger-sized *Cichlocolaptes*, and has a similar distribution, but whether the two are close to one another or whether one or both are closer to *Xenops* is uncertain. Some taxonomists have included *Heliobletus* in the latter genus, from which it is possibly not distinguishable except by minor plumage characters. *Xenops* itself is found largely in lowland tropical forests, with some populations in deciduous and lower montane forests. Three of the four species exhibit an unusual tail pattern and a conspicuous whitish malar streak, and are similar in foraging behaviour and voice. The two widespread species, the Plain Xenops (*Xenops minutus*) and the Streaked Xenops (*Xenops rutilans*), are among the most widely distributed furnariids in Neotropical forests, and are well known for their distinctive foraging technique, that of hammering open tiny dead branches and twigs. Little is known of the foraging behaviour of the Slender-billed Xenops (*Xenops tenuirostris*), but the Rufous-tailed Xenops (*Xenops milleri*) differs from the other three in many ways and has been placed by some in its own genus, *Microxenops*. Although it does share a somewhat unusual and conspicuous plumage feature, a broad

With its robust body, short bill and rather plain, featureless plumage, the **Olive-backed Foliage-gleaner** is typical of the genus *Automolus*. Members of this genus often have a contrastingly coloured throat, but lack the prominent facial markings that typify other genera of foliage-gleaners. Like its congeners, this species inhabits the understorey of humid forest, where it is inconspicuous, but it often draws attention by its repeated, rather penetrating calls. Distributed throughout the humid forest of the Amazon Basin, it is an active, acrobatic feeder that specializes in searching hanging clusters of dead leaves for prey hiding within them.

[*Automolus infuscatus cervicalis*, Iwokrama Forest Reserve, Guyana. Photo: Doug Wechsler/VIREO]

wingband, with the other three, it lacks their wedge-shaped bill, black tail markings and pale malar streak. The three "typical" xenops are rather remarkably similar in bill shape and small body size to the tiny piculets (*Picumnus*) of the woodpecker family, presumably reflecting convergence due to similar foraging behaviour, namely the chiselling of dead twigs. Less easily explained are the facts that they also share an unusual tail pattern, in which black vanes contrast with paler vanes to produce a longitudinally striped effect, and that they have similar songs, characterized by very high-pitched trills. Although xenops will adopt piculet holes for their nest-sites, no close, direct association has been reported in terms of foraging behaviour.

As is evident throughout the preceding narrative, the limits of many genera within the Furnariidae are controversial, and reanalyses using modern phylogenetic methods will almost certainly reveal inconsistencies and erroneous assumptions. The underlying problem is that traditional taxonomy, maintained largely by historical momentum rather than by explicit analyses, has placed too much emphasis on "plastic" characters, particularly bill shape. As W. J. Bock noted long ago, bill shape is perhaps the least suitable morphological character upon which to base generic limits. In addition, the Furnariidae are particularly homogeneous with respect to plumage coloration and pattern (see Morphological Aspects). Moreover, traditional taxonomy at the generic level did not incorporate any data relating to voice and behaviour, characters that, as field biologists know, often provide strong phylogenetic information.

Vaurie's 1980 monograph represents the climax of the "broad concept" of the genus, and marks the end, it is hoped, of an era of rampant but weakly supported lumping of genera by those with little or no field experience of the taxa involved. Vaurie subsumed 23 of the genera recognized in 1970 by R. Meyer de Schauensee, and thereby produced large conglomerations of species within a genus in which the only supporting evidence of such relatedness was nest structure and general similarity in body size and shape. Thus, *Thripophaga* and *Philydor*, in particular, were expanded dramatically. These expanded genera are still used by some taxonomists today, even though they are, in many cases, probably paraphyletic or polyphyletic. Fortunately, J. W. Fitzpatrick's review alerted most ornithologists to the many problems with Vaurie's classification that were immediately obvious

to those familiar with the family. As a result, the majority of subsequent authors retained the generic arrangement used by J. L. Peters in his 1951 checklist and adopted by Meyer de Schauensee in 1966 and 1970.

Nevertheless, the generic limits established by Peters are not without problems. In fact, they are controversial with regard to almost all major genera. How a genus is delimited is largely arbitrary, so long as, on the one hand, the component taxa comprise a monophyletic group and, on the other, some logical "break" ex-

The small and rather delicate **Sharp-billed Treehunter** feeds at middle and canopy levels in humid and montane forests throughout its restricted range, which is centred on south-east Brazil. It specializes in gleaning arthropods from slender branches and twigs, and is also often seen to investigate dense tangles of vines and creepers. It is an acrobatic feeder in the manner of many foliage-gleaners, but its taxonomic position is uncertain. The Sharp-billed Treehunter shares some features with Xenops, but it differs vocally from those species. It currently occupies a monotypic genus.

[*Heliobletus contaminatus contaminatus*, Campos do Jordão, São Paulo, Brazil. Photo: Edson Endrigo]

Both the **Streaked Xenops** and the **Plain Xenops** are representatives of the rather unusual birds of the genus *Xenops*. These two species have a decidedly upturned lower mandible and, although not obvious in these photographs, the bill is also compressed laterally. This interesting bill morphology is related to their foraging behaviour, that of hammering twigs and small branches to expose invertebrate prey, usually while climbing along thin branches and twigs and into vine tangles. The soft tapping sound heard as these tiny birds forage often leads to their detection in the field.

Features that the xenops share include conspicuous wingbands.

Three members of the genus, which consists of only four species, have an unusual tail pattern (again, not well illustrated here) and peculiar silvery-coloured malar stripes.

In terms of size, bill structure and foraging behaviour, therefore, they display a remarkable convergence with the piculets (*Picumnus*); bizarrely, they also have a similar tail pattern and vocalizations. These two species of xenops are remarkably widespread, and the genus is represented in all the tropical and subtropical forests of South America.

The Plain Xenops illustrated here is of the nominate subspecies, which has a disjunct range covering the forests of coastal east Brazil, eastern Paraguay and north-east Argentina. Smaller than the other subspecies, it differs further from them in a number of plumage features and may well constitute a separate species, although no obvious vocal differences have been detected to date.

ists between it and other units thus defined. Many controversies concerning generic limits are, therefore, essentially of minor importance. The issue of monophyly, however, is of critical importance if a classification is to be based on phylogeny, for the units within a taxon must all share a common ancestor, and all must be more closely related to each other than they are to any other taxa outside the group.

Although the classification currently used for the Furnariidae avoids many potential problems of paraphyly by using narrowly defined genera, many of which are monotypic, two of Vaurie's mergers at the genus level have been retained. First, the merging of *Geobates* into *Geositta* is necessary to avoid possible paraphyly of *Geositta*. The Campo Miner (*Geositta poeciloptera*), the sole species in the former *Geobates*, is probably a "paedomorphic" species, one in which what are normally juvenile characters are retained in the adult stage, with the short bill and tail being merely "tag-along" features on the route towards the evolving of smaller body size. Otherwise, this species is very similar in plumage and in display behaviour to other miners, particularly the Common Miner (*Geositta cunicularia*). Second, it is desirable to merge *Poecilurus* into *Synallaxis* because the nests and voices of the three spinetails previously placed in *Poecilurus* are extremely similar to those of some *Synallaxis* species; indeed, the similarity is greater than that among some species traditionally placed in *Synallaxis*. In fact, there appears to be no character that allows diagnosis of *Poecilurus* as a genus other than a composite of individual species' plumage patterns. Again, potential paraphyly of *Synallaxis* with respect to *Poecilurus* is avoided by the merger of these two genera.

Problems concerning species limits are numerous in the Furnariidae. As with many large Neotropical families, the hitherto existing species-level taxonomy is in general the product of a generation of taxonomists who had little appreciation of vocal differences and of the importance of these in signalling species limits. Numerous empirical studies within the last three decades have demonstrated that vocal differences are strongly associated with breaks in gene flow between populations, often with minimal accompanying differences in plumage. The lesson is that plumage differences among populations often correlate with more dramatic, biologically important differences in vocalizations that have consequences for gene flow. These plumage differences were dismissed as inconsequential in determining species limits by many authors who, in retrospect, used a version of the Biological Species Concept that too frequently emphasized similarities rather than differences.

With the benefit of detailed recent studies of various tropical suboscine birds undertaken by Whitney, Isler and Isler, Zimmer, T. S. Schulenberg, N. Krabbe, C. Marantz, A. Aleixo and others, it can be predicted that virtually all widespread "species" of suboscines that show discrete geographical variation in

One of the most distinctive of all furnariids is the

#### **White-throated**

**Treerunner** with its long, upswept bill. This arboreal forager locates its food by climbing around trees in a manner reminiscent of a nuthatch (*Sitta*), even moving downwards head-first on occasion. Typical ovenbird adaptations for this climbing lifestyle include a well-stiffened tail, the feathers of which have long protruding "spines". Recorded prey items of this unusual species include adult and larval beetles, and these are taken by the probing and active excavation of tree branches and trunks. The White-throated Treerunner is monotypic and has no obvious close relatives. It is endemic to the southern beech (*Nothofagus*) forests of southern Chile and Argentina.

[*Pygarrhichas albogularis*, Neuquén, Argentina.

The preening behaviour shown by this **Rufous Hornero** is common to all birds. Preening is a vital and routine activity that ensures that the plumage is maintained in good condition. For any flying bird it is obviously essential that the flight-feathers be kept in good working order, but preening the body feathers also ensures that their important insulating properties are maintained. This individual has almost certainly been stimulating the preen gland above the tail to secrete oil on to its bill. Preen oil is thought to contain waterproofing agents, as well as having anti-fungal and anti-bacterial properties.

[*Furnarius rufus commersoni*, Pantanal, Mato Grosso, Brazil.  
Photo: Xavier Ferrer & Adolf de Sostoa]

This **Creamy-rumped Miner** is portrayed preening, wing-stretching and sunning itself. Little information has been published on the comfort behaviour of the ovenbirds, but it probably does not differ much from that of other passerines. Preening is an important task for all birds, and much time is devoted to this activity each day. In the two left-hand pictures the bird can be seen precisely preening individual feathers by carefully nibbling them with the bill tip, zipping together feathers that have become disarranged and adding preen oil to each feather. During the process of preening, dirt particles, feather debris and parasites are removed. Wing-stretching (top right) rearranges the flight-feathers in the correct order after preening has taken place. Both during and after bouts of preening, it is not uncommon to see birds sunning themselves (bottom right). Here, the miner has ruffled up the feathers on the back to expose the underlying surface to the sun. Sunning in this way may have a number of benefits. For species that inhabit harsh, cold environments, such as the Creamy-rumped Miner, which occurs at high elevations in the Andes of central Chile and Argentina, it may be important in the efficient maintenance of body temperature. Sunning may also be beneficial in that ultra-violet light breaks down preen oil to vitamin D, which is then ingested by the birds during preening. It is also thought that the raising of the body temperature in this way may encourage parasites to be more active and therefore more easily located and removed.

Bathing in water is an important part of the process of maintaining a bird's plumage in good condition and is usually a precursor to preening. This **Rufous Hornero** is adopting one common bathing strategy by standing in water. It is ruffling its feathers, flicking its wings and tail and ducking its head beneath the surface to splash water all over its body. During this process, the feathers do not become waterlogged but merely wetted. The bird emerges after a short time to shake and flap the excess water from its plumage before starting to preen. Notwithstanding a dearth of information on the comfort behaviour of the Furnariidae, it seems highly likely that many ovenbirds living in more arid regions will indulge in dust-bathing activity, which serves the same purpose. In this form of bathing, dust replaces water and the bird simply throws dust over itself and allows this to run through its plumage before shaking it all off. In either case the aim of bathing is much the same, namely the removal of dried skin, debris, parasites and excess preen oil. Some species of ovenbird have been observed to perform anting, and this activity may be more widespread among the Furnariidae than current observations indicate. Anting involves either grabbing ants and applying them to the plumage or literally bathing in swarms of ants. The insects discharge formic acid into the plumage of the bird, and this action either benefits the bird in terms of reducing the number of active parasites that it carries or simply makes the ants more palatable before being eaten. The precise reason for this intriguing behaviour remains a matter of conjecture.

phenotypic characters across major barriers to gene flow, such as Amazonian rivers and Andean dry canyons, will be found to consist in fact of multiple biological species-level taxa. Within the Furnariidae, prime examples are the Common Miner, the Pale-breasted Spinetail (*Synallaxis albescentis*), the Striped Woodhaunter, the Scaly-throated Foliage-gleaner (*Anabacerthia variegaticeps*), the Buff-throated Foliage-gleaner (*Automolus ochrolaemus*), the Ruddy Foliage-gleaner (*Automolus rubiginosus*) and the Plain Xenops. Within each of these taxa, qualitative vocal differences already noted among populations are such as to hint strongly that more than one species is involved. Zimmer has recently demonstrated precisely this for three taxa each hitherto considered a single species, namely *Cranioleuca vulpina*, *Pseudoseisura cristata* and *Automolus infuscatus*.

Some authors already treat certain furnariid taxa as full species even though published data in support of such treatments are lacking or unsatisfactory. The splitting of the Striped Woodhaunter into two species, the "Eastern Woodhaunter" as *Hylocistis virgatus* and the "Western Woodhaunter" as *H. subulatus*, is one example. Others include the recognition of the race *chinchipensis* of the Necklaced Spinetail, the race *dissita* of the Rusty-backed Spinetail and the race *maculipictus* of the Freckle-breasted Thornbird (*Phacellodomus striatocollis*) as full species, under the respective names of "Chinchipe Spinetail", "Coiba Spinetail" and "Spot-breasted Thornbird". Although these "splits" are almost certainly valid, it is considered wiser at present to adopt a conservative approach and to await the results of formal analytical studies. Further "species" that probably contain two or more species-level taxa include the Plain Softtail, the Red-eyed Thornbird (*Phacellodomus erythrophthalmus*), the Rufous-rumped Foliage-gleaner (*Philydor erythrocerum*) and the Sharp-tailed Streamcreeper (*Lochmias nematura*). In other cases, involving taxa treated as allospecies, current species limits do not seem to accord with the delimitations that would be made on the basis of voice or other characters. This applies, for instance, to the Plain-crowned (*Synallaxis gujanensis*) and White-lored Spinetails (*Synallaxis albilora*) and to the Line-cheeked (*Cranioleuca antisiensis*) and Baron's Spinetails (*Cranioleuca baroni*).

On the other hand, some widely distributed taxa exhibit surprisingly little clear vocal differentiation, at least according to what has appeared in the literature. For example, the Buff-browed

Foliage-gleaner, the Buff-fronted Foliage-gleaner (*Philydor rufum*) and the Streaked Xenops have large ranges in which they show fairly pronounced geographical variation in plumage, but published descriptions do not indicate any major differences in voice throughout the range of any one of them. Quantitative analyses, of course, could easily dispel these qualitative impressions. Furthermore, it is clear from some examples that some barriers to gene flow are not accompanied by dramatic vocal differences. Consider, for instance, the case of the recently discovered Bolivian Spinetail (*Cranioleuca henricae*). S. Mayer and J. Fjeldså were unable to detect any major vocal differences between it and its sister-species, the Stripe-crowned Spinetail (*Cranioleuca pyrrhophia*), yet their ranges are essentially parapatric in central Bolivia, with no sign of gene flow between the two phenotypically very different populations. In fact, many species-level taxa in the genus *Cranioleuca*, in particular, seem to have very similar voices, although the caveat must be added that formal vocal analysis is lacking. Whether subtle differences in vocalizations, pronounced plumage differences without corresponding vocal differences, or other characters result in reproductive isolation has yet to be determined.

At the opposite extreme, several taxa generally treated as species are maintained at such largely through historical tradition, rather than on the basis of objective evidence or analyses. Examples of taxa that could be considered conspecific include the Plain-breasted (*Upucerthia jelskii*) and Buff-breasted Earthcreepers (*Upucerthia validirostris*), the Surf (*Cinclodes taczanowskii*) and Seaside Cinclodes (*Cinclodes nigrofumosus*), Berlepsch's (*Asthenes berlepschi*) and the Creamy-breasted Canasteros, the Beautiful and Pearled Treerunners (*Margarornis squamiger*), the Buffy (*Pseudocolaptes lawrencii*) and Streaked Tuftedcheeks (*Pseudocolaptes boissonneautii*), and the Spotted (*Premnoplex brunescens*) and White-throated Barbtails (*Premnoplex tatei*). Recognition of the Royal Cinclodes (*Cinclodes aricomae*) as a species separate from the Stout-billed Cinclodes (*Cinclodes excelsior*) is a more recent tendency, but equally lacking in convincing documentation. Nevertheless, in these cases current tradition has been followed to avoid what most would consider a worse mistake, namely lumping forms that really merit treatment as separate species. Although justification for species rank is weak, relying primarily on plumage and micro-habitat differences,

Display with singing is the primary method used by many passerines to announce territorial occupation and boundaries and, if need be, to attract a mate. The **Sharp-billed Canastero**, while singing from the tops of bushes in the early morning, opens its wings to expose the underwing and its prominent lining. This visual display probably helps to emphasize the vigour of this male in the eyes of its competitors and potential mates. Ovenbirds are frequent songsters, but most of them produce rather uniform, unappealing, invariably harsh or buzzy vocalizations. Little detailed information exists on this aspect of ovenbird biology, and no thorough bioacoustic analysis of any furnariid has yet been undertaken.

In the open campo and cerrado habitats that it occupies in southern Brazil, the **Campo Miner** uses song and wing-raising displays to declare its territory and to advertise its fitness for breeding. These birds often perch on termite mounds and repeatedly deliver their simple song. While singing, they raise their wings to expose the conspicuous broad chestnut and black wingbands. This species' song consists of a simple, almost musical "sweep" note repeated over and over again. Many ovenbird songs are similarly simple, consisting mainly of short series of harsh or buzzy notes that speed up, slow down and fall or rise in pitch. Miners also undertake short display-flights in which they hover up to 50 m above the ground while singing and, again, displaying their wing and tail patterns. Song-flights and conspicuous displays of this type are common strategies adopted by birds living in open habitats. The Campo Miner specializes in rapidly colonizing areas of recently burned grassland, and it must be semi-nomadic and capable of dispersing widely to locate suitable breeding habitat. It is currently considered to be a Near-threatened species, principally because of agricultural intensification and plantation development in its cerrado habitats. This species is often included in a separate, monotypic genus (*Geobates*), a treatment based on the fact that it is smaller than the other miners, has a shorter tail and bill and a different underwing pattern, and has a more easterly distribution.

A singing **Bay-capped Wren-spinetail** delivers dry, insect-like trills, in bursts 2-3 seconds long, from well-hidden perches in its favoured wet-marsh habitat. This furnariid is a shy and retiring resident of fresh and brackish marshes in the pampas region of Argentina, Uruguay and southern Brazil, where it particularly favours wet beds of *Eryngium* and *Scirpus*. Because of its relatively small range and its dependence on wetlands, this species is currently listed by BirdLife International as Near-threatened. Potential threats include land drainage and a lowering of the water table caused by plantation development in and around wetlands within its range.

Photo: Yves Bilat]

the two probably differ from each other as much as do the members of some other pairs of cinclodes traditionally treated as separate species, such as the Surf and the Seaside Cinclodes.

A particularly interesting case involves the cinclodes of isolated mountain ranges in western Argentina, where two species, the Cordoba Cinclodes (*Cinclodes comechingonus*) and Olrog's Cinclodes (*Cinclodes olrogi*), occur sympatrically, yet both have been considered to be no more than subspecies of the widespread Bar-winged Cinclodes (*Cinclodes fuscus*). Other workers, however, regard Olrog's Cinclodes as a subspecies of the Grey-flanked Cinclodes (*Cinclodes oustaleti*). As pointed out by one of the original describers, Olrog's Cinclodes is remarkably similar in appearance to the races *riojanus* and *yzurietae* of the Bar-winged Cinclodes. Regardless of taxonomic ranking, it remains a mystery whether the mountains of Córdoba and San Luis have been colonized by two species of cinclodes, each then differentiating into a geographical isolate, or twice by the same species, each time producing a single isolate.

Lineages within the Furnariidae show a pronounced tendency to produce geographically isolated and phenotypically differentiated populations. This is perhaps best typified by the *Cranioleuca antisimensis-baroni* complex, which provides one of the most intriguing and dramatic examples of inter-population variation to be found among Neotropical birds. This variability includes, between the extremes of the complex, a difference in body mass of nearly 100% and plumage differences substantially greater than are found among many closely related congeners. Comparison of the small, richly coloured nominate *antisimensis* of lowland west Ecuador, weighing 15 g, with the large, darker and more contrastingly patterned 30-g *baroni* of high elevations in central Peru naturally leads one to conclude that two very different species are involved; these forms, however, grade into one another in a stepwise clinal manner, and it is uncertain where to draw the line between populations assigned to one or the other "species". Populations currently treated under Baron's Spinetail at its northern extreme are more similar in size, pattern and colour to the subspecies *palamblae* of the Line-cheeked Spinetail than they are to the south-eastern populations, such as the race *capitalis*, of Baron's Spinetail. Each specimen locality seems to represent a diagnosable population, and a thorough, quantitative analysis that includes plumage, morphometrics, vocalizations and genetics will

surely produce a landmark study of geographical differentiation and speciation.

Another group in desperate need of an in-depth study is the *Asthenes wyatti-punensis* complex, which extends from the Santa Marta Mountains and northern Andes, in north Colombia, south-

The song of the **Grey-throated Leaf-tosser**, like that of its five congeners, is very uncharacteristic among the ovenbirds. It consists of pleasant whistled refrains which lack the harsh, grating qualities typical of the rest of the family. The leaf-tossers show no close affinities with any other genus except, perhaps, the monotypic Sharp-tailed Streamcreeper genus (*Lochmias*), with which they share some similarities, all of which may simply reflect convergence. Leaf-tossers are so called because of their foraging method, which involves flicking aside leaves with the bill as they seek prey on the forest floor. Unusually for a largely terrestrial furnariid genus, some species appear to press the tail against the ground when feeding or against a tree trunk when alarmed, and their stiffened tail feathers are presumably related to this behaviour.

When proclaiming its territory, the male **Araucaria Tit-spinetail** delivers its high-pitched, excited trills from the plant on which this ovenbird is totally dependent. This is an extreme habitat specialist, occurring only in *Araucaria angustifolia* trees, whether those in forests or single trees in clearings and gardens. As the distribution of *Araucaria* is restricted to the Atlantic Forest of south-east Brazil and north-east Argentina, the *Araucaria Tit-spinetail* is also confined to that region. It feeds acrobatically, either singly or in pairs, at middle and canopy levels. Because it differs from others in the genus *Leptasthenura* in bill and tail shapes and certain plumage features, it has in the past been placed in a separate, monotypic genus.

[*Leptasthenura setaria*, Campos do Jordão, São Paulo, Brazil. Photo: Edson Endrigo]

wards to northern Argentina in a series of mostly discrete populations that show pronounced geographical variation in plumage and, perhaps, voice. The form *punensis*, although currently treated as a subspecies of the Puna Canastero (*Asthenes sclateri*), has often been considered to form a separate species along with the two races *cuchacanchae* and *lilloi*. Alternatively, these same three taxa have in the past been treated as conspecific with the Austral Canastero (*Asthenes anthoides*). Similarly, the southern subspecies *azuay* and *graminicola* of the Streak-backed Canastero (*Asthenes wyatti*) were once treated as separate species, and they may, indeed, be more closely related to the Puna Canastero than to other taxa currently included in *A. wyatti*. The Streak-backed and the Puna Canasteros are considered to be sister-species, but, because they appear to intergrade in the region of Lake Titicaca, on the Peru-Bolivia border, it may be better to regard them as conspecific. Historically, interpretations of species limits in this group have fluctuated more than is the case for any other species complex in the family.

Another complex awaiting a thorough study is the *Schizoeaca* thistletails of the timber-line ecotone of the Andes. Some authors unite all members of the genus in a single species, whereas others prefer to rank the major taxa as full species. The vocalizations of all thistletails seem to be fairly similar, but the plumage patterns differ to an extent that is not found within other species-level taxa in the Furnariidae. The various thistletail taxa comprise a series of allopatric, mountain-top replacements; when major units are treated as full species, they form a classic superspecies. This lineage illustrates three themes in geographical variation of birds of the Andes: the tendencies to form leap-frog patterns of colour variation, with similar-looking taxa separated geographically by less similar-looking ones, to show latitudinal size variation that is the opposite of Bergmann's rule, and to have the most rufescent populations at the latitudinal extremes. The situation can be illustrated by the case of the White-chinned Thistletail (*Schizoeaca fuliginosa*), which is almost certainly paraphyletic with respect to the Mouse-coloured Thistletail (*Schizoeaca griseomurina*), the distribution of which it brackets to the north and south. The Mouse-coloured Thistletail is probably more closely related to a parapatric subspecies, probably the nominate race, of the White-chinned Thistletail than are the latter's northern and southern groups to each other. Perhaps a reflection of

this relationship is that the Mouse-coloured and the nominate race of the White-chinned share a plumage feature, a white eyering, that is not found in the two southern races of the latter.

With over 600 described subspecies in the Furnariidae, a rigorous re-evaluation of the diagnosability of these named taxa is a daunting task, one requiring a major scientific treatise. For cur-

Normally skulking in the dense, emergent vegetation of wet marshes, the **Curve-billed Reedhaunter** is most easily observed when singing. Males deliver a rapid series of harsh notes that ascend and then descend in pitch, before fading at the climax. The reedhaunter feeds by gleaning vegetation and takes a variety of arthropods, including ants, orthopterans and beetles. The nest consists of a ball of woven grass, leaves and fibrous material, lined with soft plant material, and attached to, or supported by, emergent vegetation. Access is via a side entrance equipped with a woven "awning", an architectural feature found in the nests of only two other ovenbird species.

[*Limnornis curvirostris*, Otamendi Reserve, Buenos Aires, Argentina. Photo: José & Adriana Calo]

This **Buff-breasted Earthcreeper** has seized a large, winged insect. The long, decurved bill of this species is used for probing and excavating in bare earth and turf for invertebrate prey, and also for gleaning food directly from the surface.

Recorded prey items of this furnariid include beetles, flies and springtails (Collembola).

Considering the large number of species in the family, the ovenbirds have remarkably narrow dietary preferences, these being almost wholly restricted to invertebrates, mainly arthropods. Commonly taken insects include cockroaches, beetles, grasshoppers and crickets, and the caterpillars of moths and butterflies. Ovenbirds are "substrate-oriented" foragers, and many specialize in searching very specific substrates for hidden and cryptic invertebrates. The Buff-breasted Earthcreeper is found in high-elevation puna grassland in the Andes of southern Bolivia and north-west Argentina.

As depicted here, it favours areas with dry, ephemeral watercourses and ravines, scattered grass and patches of bare earth. It nests at the end of a tunnel about a metre long excavated into a bank, or in a crevice in rocks. The tunnel leads to a nest-chamber that has a pad of grasses on which the two eggs are laid. As is the case for many of the high-elevation grassland birds in South America, there are comparatively few anthropogenic threats, except perhaps overgrazing. The Buff-breasted Earthcreeper is consequently fairly common, at least locally.

This **White-eyed Foliage-gleaner** has captured a snail deep in the forest understorey. This species, together with a number of other furnariids inhabiting humid forest, specializes in searching dead leaves and debris, a striking example of the "substrate specificity" that is frequently exhibited by members of the family. Dead-leaf micro-habitats have been shown to be exceptionally rich in invertebrates when compared with green foliage; this is because, during the day, they shelter a wide range of largely nocturnal arthropods.

[*Automolus leucophthalmus sulphurascens*, Minas Gerais, Brazil. Photo: Anita Studer]

rent purposes, therefore, it is considered best to rely on existing descriptions and literature as the main method of evaluation. Other than the addition of newly described subspecies, the 1951 classification of Peters has been largely maintained herein, unless published revisions have indicated otherwise. In some cases, however, subspecies recognized by Peters or others have been synonymized with other taxa in the current classification. Detailed examination of museum material, including that in the extensive collections at the Museum of Natural Science, Louisiana State University, in the USA, has revealed that, in these instances, the characters that supposedly allow diagnosis clearly fail to do so. Just one of many examples illustrating the complexity of such problems is provided by the Bar-winged Cinclodes. In this case, it is unclear whether the forms *rivularis* and *longipennis*, both described in the nineteenth century, are valid races. It is possible that the whiter individuals from the drier areas of the Peruvian Andes are the "true" representatives of the subspecies *albiventris*, leaving at least one of the other names, presumably *longipennis*, available for humid-slope birds. The form *rivularis*, of the Junín region of Peru, is supposed to differ from *longipennis* in having a less rufescent back, paler flanks, and less heavily margined breast feathers; although this does, indeed, apply to some specimens from the Junín region, the type locality for *rivularis* is Maraynioc, at or near the humid eastern slope.

Although many subspecies were described from inadequate samples of specimens and localities, and before the word "statistics" had even entered the vocabulary of biologists, the "benefit of the doubt" has generally been accorded to named taxa when discrete differences are apparent, even if appropriate sampling of specimens from intermediate regions is lacking. In contrast to temperate latitudes, geographical variation in tropical birds, largely sedentary and more sensitive to barriers to gene flow, is often discrete and abrupt, with named entities an appropriate typology for cataloguing such variation. Nevertheless, it would be surprising if any modern subspecies typology, if rigorously analysed, survived without revision. For example, recent examination of specimens revealed at least four undescribed geographical populations, of the Dark-breasted (*Synallaxis albigularis*) and the Rufous Spinetails (*Synallaxis unirufa*), Baron's Spinetail and the Streak-throated Canastero (*Asthenes humilis*), that appear to merit subspecies rank. Other subspecies, as yet undescribed, have

been discovered by Fjeldså, Krabbe and others; these involve, for example, the Tawny Tit-spinetail (*Leptasthenura yanacensis*), the Puna Thistletail (*Schizoeaca helleri*), the Sooty-fronted Spinetail (*Synallaxis frontalis*), the Creamy-breasted Canastero, the Scribble-tailed Canastero (*Asthenes maculicauda*) and the Line-cheeked Spinetail.

The number of species in Furnariidae will undoubtedly increase in the coming decades as new species, and perhaps even further new genera, are discovered. The lesson from the astounding discovery of the Pink-legged Graveteiro (*Acrobatornis fonsecai*) should not be lost on field biologists or conservationists. Nests of this species are plainly visible from one of Brazil's major highways, and virtually every ornithologist who has worked in eastern Brazil over the last century has passed literally within sight of the bird, yet this furnariid, so different from any other that it clearly demanded the description of a new genus, remained undetected until 1994. In many ways, this is the most remarkable new bird species to have been discovered in the Western Hemisphere in the last 25 years. Almost as amazing is the fact that the Long-tailed Cinclodes (*Cinclodes pabsti*) remained undescribed until 1969; not only does southern Brazil have a long history of exploration by prominent ornithologists, but the cinclodes are typically among the most conspicuous ovenbirds and some of the easiest to find.

Furthermore, some other species of ovenbird are known from a single locality or a closely grouped set of localities, examples being the Orinoco Softtail, the Hoary-throated and Bolivian Spinetails and the Cipo Canastero (*Asthenes luizae*). Others again, such as the Russet-mantled Softtail, the Royal Cinclodes, the two *Xenerpestes* greytails and the Bolivian Recurvebill (*Simoxenops striatus*), occur at widely scattered localities, but only a few specimens of each are available. Strictly from a statistical sampling perspective, therefore, it is highly likely that additional species remain to be detected, especially when one considers how much of South America has still to be investigated thoroughly by competent field ornithologists.

Besides the Pink-legged Graveteiro and the Long-tailed Cinclodes, seven other furnariids new to science have been discovered since Meyer de Schauensee's classic 1970 inventory of South American birds. These are the Apurímac Spinetail (*Synallaxis courseni*), first described in 1971, the Vilcabamba (*Schizoeaca*

Searching for invertebrates in shallow running water is one foraging strategy of the **Grey-flanked**

**Cinclodes**. This species inhabits open grassy and rocky habitats, from sea-level to about 4000 m, in central and southern Chile and adjacent areas of Argentina. At higher elevations it appears to favour the vicinity of streams. It obtains its food by gleaning invertebrates from the surfaces of vegetation, bare earth and rocks. The genus in general is notably tied to wetland habitats and their margins. One exception is the **Cordoba Cinclodes**, pictured here (below) with a captured earthworm.

This species, which is confined to west-central Argentina, favours open grassy, often rocky, habitats in submontane areas. It, too, feeds by gleaning invertebrates from bare earth, vegetation and rocks, and its recorded food items include a range of arthropods, as well as some seeds. Although the majority of food items taken by ovenbirds consist of arthropods, the various species of cinclodes demonstrate that a range of other prey can be important to some genera.

Unusually among the Furnariidae, molluscs make up a high proportion of the prey of many *Cinclodes* species, especially those which specialize exclusively on marine intertidal habitats. Seeds and fruit have been recorded as food for a number of ovenbirds and may be an important part of the diet of some species. In addition, small vertebrates are taken by the members of several genera.

In the harsh environment in which it lives, the **Blackish Cinclodes** has adapted to the conditions by using a diverse array of food resources. It frequents rocky and gravelly beaches on the islands and coastline of the southern tip of South America and the Falkland Islands. Its prey items include a range of arthropods and marine invertebrates, which it captures by employing a variety of foraging techniques. Strandline kelp debris and floating mats of kelp are important feeding areas and are carefully scrutinized for hidden prey; using the bill, the birds often hack into the rotting kelp to expose prey animals. As demonstrated in the lower photo, the Blackish Cinclodes is also frequently found in the vicinity of colonies of marine mammals and seabirds, where it chases invertebrates attracted to these sites and disturbed by the moving animals. It also searches seabird faeces and nests for invertebrate prey, and has been recorded as feeding on damaged eggs and on scraps of fish and other left-over food items brought to the chicks in seabird nests. The Blackish Cinclodes is an incredibly tame bird and will even follow humans as they walk along the beach, taking advantage of the invertebrates disturbed by the tramping feet. When chasing flying insects, it sometimes resorts to brief aerial sallies from the ground. Understandably for such a tame bird, it has suffered a marked reduction in its range following the introduction of ground predators such as rats and cats. As a result, this cinclodes is now very rare on the mainland and is absent from many of its former haunts.

*vilcabambae*) and Perija Thistletails (*Schizoeaca perijana*), described in 1972 and 1977, respectively, Olog's Cinclodes, described in 1979, the Alagoas Foliage-gleaner (*Philydor novaesi*), described in 1983, the Cipo Canastero, described in 1990, and, finally, the Bolivian Spinetail, described in 1997.

### Morphological Aspects

Although Furnariidae is one of the most diverse families in the world in terms of bill and tail morphology (see below), its members share a general outward appearance that typifies the ovenbirds. The mostly brown plumage, the constant pattern themes such as prominent streaks, throat patches, a long and often graduated or "spiny" tail, wingbands and tail patches that show in flight, combined with unmusical and often harsh voices, usually wary or sneaky behaviour, and often moderately to strongly acrobatic perching behaviour and clambering locomotion along branches, with consequently oversized feet, all signal "ovenbird" to the ornithologist.

Ovenbirds range in size from the tiny Slender-billed Xenops, only 10 cm in total length, to the Brown Cachalote (*Pseudoseisura lophotes*) and the Flammulated Treehunter (*Thripadectes flammulatus*), both some 25 cm long. The lightest in weight are about 8 g, as in some *Leptasthenura* species, whereas the heaviest is the 109-g White-bellied Cinclodes (*Cinclodes palliatus*).

The overwhelming majority of furnariids are basically brown in colour, perhaps to a greater degree than is evident in any other of the world's major bird families. Although the Blackish Cinclodes (*Cinclodes antarcticus*) comes close, not one species is all black, which is rather unusual for such a large family, especially in the suboscines. Only a single species, the White-bellied Cinclodes, is truly all white in a substantial portion of its plumage, and in only four species is the predominant colour something other than a shade of brown. The two *Xenerpestes* greytails, as well as the recently discovered Pink-legged Graveteiro, are predominantly grey, with some black, whereas the Orange-fronted Plushcrown is mostly greenish and yellowish. This last is the only furnariid with any bright coloration of this sort, and, in fact, the plushcrown's uniqueness within the family in terms of colour once led some to doubt whether it was a true member of the

Furnariidae. That all four of these "oddly" coloured ovenbirds are somewhat local or rare suggests that these evolutionary "experiments" in coloration have not been particularly successful. Whether they are recent phenomena or relicts of an ancient but now extinct furnariid radiation is not known.

Yellow is the only bright spectral colour found in ovenbird plumage, albeit rarely. In addition to the Orange-fronted Plushcrown, which has a yellow-orange forehead and a yellow throat, four other species have small patches of yellow on the throat. These are the Chotoy Spinetail (*Schoeniophylax phryganophilus*), the Sulphur-throated Spinetail (*Cranioleuca sulphurifera*), the Yellow-chinned Spinetail and the Pearled Treerunner. Others, such as the Speckled Spinetail (*Cranioleuca gutturata*) and the Rufous-tailed Foliage-gleaner (*Philydor ruficaudatum*), approach the condition of having pure yellow in the plumage.

Within the broad colour "brown", however, the Furnariidae show an unparalleled diversity of shades, at their extremes flirting with red, orange, yellow and black. Some of the shades of chestnut, rufous and ochraceous are so intensely bright that they appear almost to glow, like spectral colours. At the other extremes, many species of arid areas are so dull in coloration that to call them either greyish-brown or brownish is a generous stretch of the limits of these colours.

Compensating to a degree for lack of bright colours, many ovenbirds have complex plumage patterns that make them comparatively attractive. Many of the spots and stripes that contribute to these patterns are emphasized by contrasting margination of the feathers so marked, making them stunning. Species such as the Pearled Treerunner, the Point-tailed Palmcreeper and the Flammulated Treehunter display some of the most striking plumage patterns among Neotropical birds. Many furnariids also have conspicuous, contrasting patches of paler colour in the tail and wings that are revealed in flight. In spite of the conspicuous wingbands found in several genera, the family as a whole is notable for the near absence of prominent wingbars.

Although the display repertoires of ovenbirds are poorly documented, plumage patterns are clearly emphasized during display in some genera. The semi-concealed throat patch of many *Synallaxis* spinetails and *Asthenes* canasteros is revealed during displays, when the throat feathers are erected to expose their darker bases. The cinclodes raise their wings while singing, exposing

The stout bill of this **Streak-capped Treehunter** was more than a match for a comparatively large Anolis lizard. The feeding habits of this furtive, understorey furnariid are poorly known, and vertebrates had not previously been confirmed as part of its diet. Other members of the genus *Thripadectes*, however, are known to take vertebrates, mainly frogs, lizards and salamanders. These supplement a diet of what are more typical prey of furnariids, such as molluscs, beetles, cockroaches, katydids, spiders and caterpillars. The Streak-capped Treehunter occurs in the montane forest of north Venezuela and the Andes, southwards to northern Ecuador.

[*Thripadectes virgaticeps*  
*virgaticeps*,  
Carchi, Ecuador.  
Photo: Doug Wechsler/  
VIREO]

A rather catholic taste in invertebrate prey is exhibited by the thrush-like **Rufous Hornero**, an individual of which is here portrayed as it captures and dispatches a freshwater crab.

This species forages while strutting around with a characteristic "high-stepping" gait, and gleans invertebrates and seeds from areas of bare earth and leaf litter. The varied diet of this large hornero is well studied compared with that of many ovenbirds and appears to include good numbers of ants, which is unusual among passerines.

Other recorded prey items include beetles, termites, crickets, mole-crickets, caterpillars, grasshoppers, hemipteran bugs, worms, spiders and snails.

The Rufous Hornero has a huge range that covers much of lowland southern South America, where it is found in open second growth, farmland, pasture and urban parks and gardens. It favours areas with disturbed, bare soil and is especially numerous near human habitations. It is a well-known and popular species throughout its range, and has even been designated the national bird of Argentina. Its preference for open, often anthropogenic habitats, coupled with the widespread deforestation of South America in historical times, has enabled this furnariid to expand its range dramatically in recent decades.

[*Furnarius rufus paraguayae*,  
Rio Pilcomayo  
National Park,  
Formosa, Argentina.

Calo]

The distinctive **Sharp-tailed Streamcreeper** is often encountered as it stands in shallow running water, seeking invertebrates on the beds of streams and small rivers. This individual has taken a small larva or worm. The streamcreeper also gleans items from moss-covered rocks in the streambed and from bare mud and leaf litter along riparian corridors. It is unusual in being the only burrow-nesting ovenbird that builds a small domed nest of plant material at the end of the tunnel. Although the genus is monotypic, this species has several disjunct populations: in northern Venezuela, the Andes, and eastern Paraguay, south-east Brazil, north-east Argentina and Uruguay. It may be that these represent more than one species.

[*Lochmias nematura*,  
Caraça National Park,  
Minas Gerais, Brazil.

prominent wingstripes. Species in several genera have erectile crown feathers that also seem to be emphasized during displays (see General Habits), as demonstrated by, for example, the Crested Hornero (*Furnarius cristatus*), the Sulphur-throated Spinetail, the Lark-like Brushrunner and the Brown Cachalote. Others, including the Tufted (*Leptasthenura platensis*) and Araucaria Tit-spinetails (*Leptasthenura setaria*) and the Crested Spinetail (*Cranioleuca suberistata*), have slightly elongated crown feathers that are possibly also used during display.

The Furnariidae exhibit a wide range of bill shapes, probably the largest of any Neotropical family. The typical insectivore bill shape is by far the most common, and it is the only or the predominant one in several of the large genera, such as *Geositta*, *Cinclodes*, *Leptasthenura*, *Cranioleuca*, *Synallaxis*, *Asthenes*, *Philydor* and *Automolus*. A longer, relatively thinner bill is associated with the probing of substrates, and is found in such genera as, for instance, *Upucerthia* and *Sclerurus*. A decurved bill, associated with probing and digging, is possessed by some species, including the Slender-billed Miner (*Geositta tenuirostris*), several *Upucerthia* earthcreepers and the Stout-billed and Royal Cinclodes. A different type of bill, wedge-shaped or chisel-shaped bill, with the distal portion of the maxilla distinctly upturned, and with the mandibles laterally compressed in some cases, is well represented in the family, being possessed by, for example, *Simoxenops*, *Megaxenops*, most *Xenops*, *Pygarrhichas* and, to a lesser degree, *Syndactyla* and *Anabazenops*. This bill shape is usually associated with chiselling motions used to remove material from substrates or to enlarge existing cracks.

With the exception of a few families including the pheasants and partridges (Phasianidae) and the birds-of-paradise (Paradisaeidae), in which the tail is used prominently in display, perhaps no other avian family shows so much variation in tail shape as does Furnariidae. This is reflected in the English names of many groups, such as wiretail, thistletail, spinetail, softtail, prickletail and barbtail, as well as in many scientific names: *Aphrastura* means "strange tail", *Leptasthenura* "thin weak tail" and *Sclerurus* "stiff tail", and *Pygarrhichas* can be translated as "rump with a basket". Much of the variation in tail structure is associated with varying uses of the tail as a brace during foraging. At one extreme is the tail of the truly scansorial, climbing, species such as the White-throated Treerunner and the *Margarornis* treerunners,

in which the rachis of some rectrices is stiffened throughout its length, with the distal ends of the shafts downcurved and devoid of barbs; the tail is used as a brace during climbing. A virtual continuum exists from this extreme to the typical passerine tail, which lacks such modifications, with dozens of species in such genera as *Cranioleuca*, *Berlepschia*, *Pseudocolaptes* and *Cichlocolaptes* showing some degree of strengthening of the tail for clinging or acrobatic manoeuvring. Although modifications of the tail are in general good predictors of climbing ability in the Furnariidae, there are three genera in which a stiffened tail or the possession of tail spines is not clearly associated with such foraging behaviour. The leaflossers, in *Sclerurus*, have stiffened rectrix shafts, but these birds are strictly terrestrial in their foraging; nevertheless, several observers have noted that, when flushed, they cling vertically to trees and branches, and Whitney has found that they roost in this position at the bases of trees. Unlike *Sclerurus*, the Sharp-tailed Streamcreeper has protruding tail "spines", but the rectrix shafts are not so strong as those of the leaflossers. Perhaps the streamcreeper, too, will eventually be found to cling occasionally to vertical trunks, or possibly rocks. Most mysterious are the cachalotes in the genus *Pseudoseisura*, which have both slightly stiffened rectrices and protruding terminal spines. To date, they have not been reported as using the tail in any way as a brace; indeed, their foraging behaviour indicates that they are among the least likely in the family to do so.

Many ovenbirds have a disproportionately long tail, as is evident in such species as Des Murs's Wiretail, many *Schizoeaca* thistletails, *Leptasthenura* tit-spinetails and *Synallaxis* spinetails. These have what is, in relation to body size, some of the longest tails of any bird in the world, at least if one disregards those species, such as many pheasants, hummingbirds, birds-of-paradise, whydahs (*Vidua*) and others, in which the tail is known to function as an ornament during display. Many of the longer-tailed furnariids also have somewhat "decomposed" vanes, especially distally, where gaps between the barbs are unusually large. At the other extreme, a few ovenbirds have a disproportionately short tail, examples being the Campo Miner and some xenops.

The Furnariidae are fairly homogeneous with regard to wing shape. Most have relatively short, rounded to somewhat pointed wings that reflect their generally sedentary status and the absence of aerial foraging. Sedentary species inhabiting dense vegeta-

tion, such as members of the genera *Synallaxis*, *Certhiaxis*, *Schizoeaca* and *Thripadectes*, tend to have the most rounded wings, with a minimum of primary extension. Some terrestrial foragers are also represented at this extreme, among them species in *Sclerurus* and *Upucerthia*, although not the migratory Scale-throated Earthcreeper (*Upucerthia dumetaria*). Those furnariids that, although sedentary, fly frequently between foraging sites tend to have somewhat longer, more pointed wings, this being the case for species in *Leptasthenura*, *Cranioleuca*, *Margarornis*, *Pseudocolaptes*, *Philydor* and *Xenops*. The only ovenbirds with long wings and large primary extensions are the miners and the cinclodes, all of which typically make long flights between foraging sites, and several of which are migratory. It is also of relevance that many, perhaps all, miners give song-flight displays, and short aerial displays have been reported for three species of cinclodes.

Although comparative quantitative data are not available, ovenbirds strike most field observers as having oversized legs and feet in terms of thickness. This is presumably associated with the high frequency of acrobatic manoeuvres requiring stronger grasping power, which is evident during foraging. Possibly as a consequence, many furnariids use their feet to hold large prey items while they kill and eat them.

The morphological radiation of the Furnariidae has generated many cases of what are widely regarded as examples of convergent evolution, involving taxa that are similar in morphology and ecology to taxa in other, often distantly related, bird families. This convergence is often reflected in the English and scientific names. Although rigorous quantitative evaluation of the proposed examples of convergence is lacking, many of these are striking, at least superficially. One of the most remarkable is the aptly named Wren-like Rushbird, which is amazingly similar in plumage, morphology, behaviour and habitat to the Marsh Wren (*Cistothorus palustris*) of the family Troglodytidae. The harsh mechanical nature of some of its notes and its high rate of song delivery also suggest bioacoustic convergence. Indeed, a comparison of the vocal repertoires of these two would make a fascinating study; the suboscine rushbird would be predicted to have a drastically limited repertoire compared with the astounding individual repertoires documented for the Marsh Wren by D. E. Kroodsma. The marsh-inhabiting Curve-billed Reedhaunter is

remarkably similar in plumage and behaviour to some Old World marsh-dwelling *Acrocephalus* warblers. Similarly, the curve-billed members of the genus *Upucerthia* bear a reasonable resemblance to several thrashers (*Toxostoma*) of the family Mimidae, and both groups inhabit arid scrub. The White-throated Treerunner is widely considered to be partially convergent with the large *Sitta* nuthatches in plumage and behaviour, but its fortified, bark-bracing tail differs from that of the nuthatches. Tit-spinetails have long been considered convergent in morphology and behaviour with the Old World *Aegithalos* long-tailed tits; this is reflected in their English name, as well as in the scientific name of one, the Plain-mantled Tit-spinetail (*Leptasthenura aegithaloides*).

Less convincing examples of convergence mentioned by various authors include the general similarities between the miners and some larks (Alaudidae) or wheatears (*Oenanthe*), between some canasteros and the *Anthus* pipits, and between the cachalotes and the jays of the Corvidae family. The similarities to birds living elsewhere in the world are often alluded to in the scientific names of the genera, with appropriateness ranging from good to not so good. *Cinclodes*, meaning "like a dipper (*Cinclus*)", and *Certhiaxis*, or "treecreeper (*Certhia*)-spinetail", are fitting enough, whereas it is less easy to accept, for example, *Geositta*, *Upucerthia*, *Pseudocolaptes*, *Cichlocolaptes*, *Anabacerthia* and *Pseudoseisura*, which mean, respectively, "earth nuthatch", "hoopoe (*Upupa*)-treecreeper", "false woodpecker", "thrushy woodpecker", "climbing treecreeper" and "false wagtail (Motacillidae)".

The Furnariidae are notable for their lack of sexual dichromatism. No species shows a strong difference in plumage between the sexes, but a few exhibit subtle differences. Females of the Wren-like Rushbird, the Ruddy Spinetail (*Synallaxis rutilans*), the Chestnut-throated Spinetail (*Synallaxis cherriei*) and, perhaps, the Plain Softtail are slightly paler than their respective males. The general absence of sexual dichromatism in the family is consistent with the widespread suspicion, despite limited data, that differences in the sexes' roles during breeding are minimal and that variations from strict monogamy are few.

In terms of size, sexual dimorphism is slight. For virtually all species for which samples are sufficient, males average slightly larger than females in linear measurements. K. Winker and col-

**This Hudson's Canastero** is busy feeding its chicks and has caught a grasshopper (*Leptysma argentina*). This secretive ovenbird inhabits tall grass and sedges in and around marshes in the pampas region of eastern Argentina and Uruguay. It has been recorded as feeding also on caterpillars, beetles, pentatomid bugs and Hymenoptera. There is little information on the foraging techniques employed by this species but, like other canasteros, it presumably gleans arthropods from the ground, vegetation and the bases of sedge and grass tussocks. The nest is either a simple hollow beneath a clump or tussock of vegetation, and with a woven dome of grass and thin twigs, or a spherical woven mass slightly off the ground in a grass clump.

[*Asthenes hudsoni*, Argentina.  
Photo: Yves Bilat/Ardea]

Food items such as this juicy caterpillar will make an ideal offering for the chicks of the **Bay-capped Wren-spinetail**.

This furnariid gleans invertebrates from marsh vegetation, and has been recorded as taking a variety of arthropods such as beetles, Neuroptera and Hymenoptera. The well-hidden nest is a deep cup of grass and reeds, placed low down, or on the ground itself, and protected from above by dense vegetation.

This ovenbird is similar in size and shape to many of the other "spinetails", but its plumage is distinctive.

It occupies a monotypic genus, although it has in the past been placed within the *Synallaxis* spinetails, and some authors have postulated that it demonstrates affinities with the *canasteros* (*Asthenes*) and the tit-spinetails (*Leptasthenura*). The Bay-capped Wren-spinetail is just one of the many ovenbirds that have a direct association with wetland habitats.

A high proportion of the family is found in such habitats, ranging from the rocky, intertidal marine zones to the remote bogs of the high Andes.

Aside from those furnariids that, like the Bay-capped Wren-spinetail, frequent freshwater marshes with abundant emergent vegetation,

there are also the *Cinclodes* species, most of which are found at the water's edge in a variety of different habitats, the riparian *Certhiaxis* spinetails, and a stream-haunting specialist, the Sharp-tailed Streamcreeper (*Lochmias nematura*).

[*Spartonoica maluroides*, Salado's Depression, Buenos Aires, Argentina.  
Photo: Yves Bilat]

These two species of leaftosser are both bringing large prey items with which to feed chicks in the nest. The **Grey-throated Leaftosser** in the upper photo has caught a large orthopteran, whereas the **Rufous-breasted Leaftosser**, depicted below it, is carrying a big spider in its bill. The six leaftosser species are similar in their habitat requirements, and all have a specialized feeding technique. They occur in damp areas of humid and montane forest in Middle and South America, where they tend to be a scarce component of the avifauna and are usually encountered singly or in pairs. Leaf tossers feed by gleaning, probing moist soil, leaf litter and rotten wood, and flaking apart deep leaf litter by vigorously flicking it aside to expose prey. It is this last activity that gives these birds their vernacular name. While foraging energetically in this manner, they often press the tips of the tail feathers, the shafts of which are stiffened, into the ground. The recorded diet of the genus includes termites, cockroaches, beetles, annelid worms, ants, spiders and small frogs. The tackling of large items, incidentally, is not unusual in the ovenbird family, many members of which are notable among passerines for using their feet as a means of helping to subdue and dispatch prey. The degree of substrate specialization displayed by the leaf tossers is just one example in a family in which such specialization is commonplace. The variety of substrates utilized by various furnariids includes, among others, tree branches and trunks, live foliage, hanging dead leaves, epiphytes, fallen logs, bamboo stems and bare ground.

Like many species in its genus, the **Cordilleran Canastero** forages by gleaning a variety of arthropods from the ground and, occasionally, from low vegetation. This foraging behaviour reflects the habitat preferences of the majority of the canasteros, which occur mainly in open and semi-open habitats with rocky or grassy terrain. Prey taken by this species includes ants, cockroaches and beetles. Foraging techniques adopted by some of the other canastero species include acrobatic, arboreal gleaning in low vegetation, as well as searching and even burrowing into tussocks, and occasional sallying after aerial insects or flying up to grab insects from low vegetation. The Cordilleran Canastero occurs in a variety of grassland and scrub habitats, from sea-level to 4500 m, ranging from Peru southwards to southern Argentina. Although it shows a strong preference for grassland, it can also be found in dry montane scrub, *Polylepis* thickets and open woodland.

Adolf de Sostoa]

leagues have presented the most sophisticated analyses of sexual dimorphism for any members of the family. For the Buff-throated Foliage-gleaner, they found that males had significantly longer wings, tail and tarsi, but that the difference in bill length was not statistically significant. Males of the Plain Xenops had significantly longer wings and tails than those of the females, but the differences in bill and tarsus lengths were not significant. Perusal of Vaurie's extensive tables of measurements suggests that these trends, with the sexes exhibiting the greatest differences in wing and tail lengths and the least in bill length, should be almost universal within the family. The sole exception to the above pattern is the tuftedcheeks, the females of which have a considerably longer bill than that of the males, the degree of sexual dimorphism varying geographically. In the Streaked Tuftedcheek, the difference is so great that individuals can be sexed by sight in the field. Because of this, and the fact that the foraging behaviour of the two tuftedcheeks is amenable to visual studies, the study by S. Sillett and colleagues has set the stage for a fascinating research project with *Pseudocolaptes* for somebody interested in the underlying causes of sexual dimorphism.

Distinct juvenile plumages are found in many species of furnariid. Precise plumage sequences have yet to be worked out rigorously, and in many genera the skull never fully ossifies, thereby complicating the determination of age of individuals. Generalizations are, therefore, premature and synthesis impossi-

ble. In many cases, attribution of a plumage to the category of "juvenile" is based on assumption, and all such designations should be treated with caution. Nevertheless, it seems that the majority of ovenbirds possess a juvenile plumage that differs moderately to strongly from the adult plumage. Its scarcity in specimen series of most species suggests that its duration may be only several months or less. Most juvenile plumages are characterized by one or more of three themes. These are an ochraceous wash on the underparts, an increase in dusky feather margins that produces a scaly appearance, usually on the throat and breast, and an absence of, or reduction in, the contrasting throat or crown patches that characterize adult plumage. The taxonomic distribution and phylogenetic implications of these themes is in need of analysis. So far, there is no documented example of an ovenbird species breeding in any sort of juvenile or immature plumage.

For no species in the family have the timing and sequence of moults been elucidated. Nothing, however, suggests that the Furnariidae are unusual in these respects. The degree of overlap, or lack of it, between timing of breeding and moult has not been quantified in detail for any species. Moults that produce seasonal changes in plumage types are unknown.

Just as with the plumage, the Furnariidae are relatively dull and homogeneous with respect to the coloration of the irides, bill, tarsi and toes. Analysis of bare-part coloration among the ovenbirds, as for most birds, is limited by the absence of a feasi-

In characteristic posture, this **Wren-like Rushbird** intently forages for invertebrates on a mat of floating vegetation. This unusual furnariid gleanes items from vegetation, and occasionally from bare mud and water, in fresh and brackish marshes with abundant emergent vegetation (especially *Scirpus*). The rushbird provides the most striking example of convergence. In plumage, morphology, behaviour and habitat and, to some extent, vocally, it is remarkably similar to the Marsh Wren (*Cistothorus palustris*) of North America. It occupies a monotypic genus of uncertain affinities, but its nest architecture points to a possible relationship with the two reedhaunters (*Limnornis*, *Limnornites*).

[*Phleocyptus melanops melanops*,  
El Palenque,  
Buenos Aires, Argentina.  
Photo: Andy & Gill Swash]

ble, quantitative scoring methodology. Much or most of the variation evident from specimen labels is probably due to differences in preparators' scoring techniques, to light conditions at the time of scoring, and to varying degrees of post-mortem change. With these problems in mind, the following generalizations are possible. The vast majority of furnariids have brown or dark brown irides, but some have reddish, chestnut or yellow irides. In some species, iris colour shows a puzzling range of variation among specimens that does not seem to be associated with sex. Exam-

ples of this phenomenon include the Chotoy Spinetail, several *Synallaxis* and several *Cranioleuca* spinetails, the Yellow-chinned Spinetail, the Rufous-fronted (*Phacellodomus rufifrons*), Little, Streak-fronted and Freckle-breasted Thornbirds, the Equatorial Greytail (*Xenerpestes singularis*), the Brown-rumped Foliage-gleaner (*Automolus melanopezus*) and the Henna-hooded Foliage-gleaner (*Hylocryptus erythrocephalus*). The bills of most ovenbirds are typically dark, with the lower mandible often paler than the upper. The tarsi and toes are generally dull and rather

**Tufted Tit-spinetails** forage actively, and at times acrobatically, as they glean such items as beetle larvae and small spiders from foliage, slender branches and twigs. The individual portrayed here appears to be intently searching for prey among epiphytic lichens, and is obviously using its tail for support. The foraging technique of this species is typical of the members of this genus, which are largely arboreal, feeding at all levels from the understorey up to the canopy. Tit-spinetails usually occur in pairs or small groups, and are often found in mixed-species feeding flocks, even on occasion alongside other members of the genus.

[*Leptasthenura platensis*,  
Salado's Depression,  
Buenos Aires, Argentina.  
Photos: Yves Bilal]

When foraging, usually low down in the forest, the **Ruddy Foliage-gleaner** occasionally pecks and probes at decaying branches. Other techniques include gleaning from dead leaves and, at times, flicking through leaf litter in leaf-tosser (*Sclerurus*) fashion. As well as arthropods, it takes some small frogs and lizards. This ovenbird, found locally in the Middle American mountains, the Andean foothills and the Guianan Shield, appears to favour hill and lower montane forest, and may be tied to damp, densely vegetated ravines. The population in southern Venezuela, the Guianas and Amazonian Brazil, differing vocally and in size, probably represents a separate species.

[*Automolus rubiginosus nigricauda*,  
El Placer,  
Esmeraldas, Ecuador.  
Photo: Doug Wechsler/  
VIREO]

dark, usually some shade of olive, grey or brown, or black, paler shades of pinkish or yellowish being relatively scarce; tarsus colour tends to be homogeneous within a genus. The only two species with brightly coloured tarsi are the Orange-fronted Plushcrown, which has bright yellow or orange-yellow legs, and the Pink-legged Graveteiro, with bright pink legs. The presence of such bright coloration in these two members of a large family generally having dull tarsi is another character to suggest that they are closely related, if not sisters. Areas of bare facial or throat skin are not found in the Furnariidae.

Most ovenbirds use flight to move from one spot to another, generally flying only very short distances at a time. As mentioned above, this is reflected in their wings, which are typically relatively short, and rounded to modestly pointed. Exceptions include the miners and the cinclodes, all inhabiting open country, where long flights are frequently used to move from one foraging spot to another. At the other extreme, many species found in dense undergrowth are known for their weak, fluttering flight, and seldom fly more than a few metres at a time; the *Schizoeaca* thistletails and the *Synallaxis* spinetails are examples.

The number of furnariids that climb or hitch along or up branches is very high. Moreover, the number of species for which the characteristic motion is to climb vertical branches is probably higher in Furnariidae than in any family except those consisting almost exclusively of climbers, such as the woodpeckers, the nut-hatches (*Sittidae*), the treecreepers (*Certhiidae*) and, especially, the woodcreepers, the last of which is, in any case, probably better included within the Furnariidae as its most scansorial lineage (see Systematics). Even with the exclusion of the dendrocolaptids, the number of species with additional modifications for climbing, such as stiffened tail shafts, strong and bare tips of the rectrices, and strong toes, is exceptionally high. The use of various hanging manoeuvres when foraging is probably greater than in any other species-rich family of birds except the tits (*Paridae*). Many ovenbirds frequently hang downwards or even upside-down to reach the undersides of branches or suspended dead leaves.

Locomotion for those species that are mainly terrestrial naturally involves running, scuttling and walking to various degrees. Most terrestrial species move by means of short scuttling walks and runs, and some short hops. Hopping to the extent found in the thrushes, for example, is unknown. The only members of the

family that have a pronounced high-stepping walk are the horneros. The miners, the *Upucerthia* earthcreepers and the Lark-like Brushrunner can run fast for considerable distances, as also can horneros when frightened.

Finally, it is of interest to mention the peculiar musty odour emitted by at least some of the spinetails. This is sufficiently strong that a museum curator can tell immediately when the spinetail cabinet is open. The odour is similar to that given off by specimens of two tanagers (*Thraupidae*), the Black-capped (*Hemispingus atropileus*) and Orange-browed Hemispinguses (*Hemispingus calophrys*), and also, as noted by H. D. Pratt, by the Hawaiian honeycreepers (*Drepanididae*). It is rather faint and difficult to detect on individual specimens, and perhaps not easy to distinguish from odour secondarily acquired by spinetails through being housed with specimens that actually produce it. Presumably, the odour is derived from some component of the oil of the uropygial gland, but it is not known whether it has any function, such as ectoparasite repulsion.

## Habitat

It would be far easier to discuss the habitats not occupied by members of the Furnariidae, rather than those in which they do occur. In fact, every terrestrial habitat in South America that supports primary productivity also has at least one species of ovenbird. Furnariids are found from the highest elevations that support life in the Andes all the way down to lowland Amazonia, which harbours the world's richest bird communities. Their habitats range from perpetually wet cloudforest to virtually rainless desert, and also include river-island mudflats, coastal sand dunes, saltwater marshes, and even the rocky intertidal zone. In fact, the two ovenbirds living in the last-mentioned habitat, the Seaside Cinclodes and the Surf Cinclodes, may be the only passeriform species found only in a truly marine environment. Furnariids are also found in virtually all human-created habitats, from urban parks to degraded pastures.

Ovenbirds are prominent components of all bird communities in South America. The corollary of this extreme range in habitats occupied is that the furnariid lineage shows extreme flexibility in the limits of physiological tolerances, with several spe-

The boldly patterned and striking **Pearled Treerunner** is an acrobatic feeder, often hanging upside-down when searching for food. It creeps along branches, including the undersides, using its tail for support if necessary, and often ventures out to the slender terminal twigs of trees. The Pearled Treerunner lives in the Andes, from Venezuela to Bolivia, and favours the mossy, epiphyte-covered trees of high-elevation elfin forest. Here, it gleans arthropods directly from epiphytes and, occasionally, from bark and dead leaves. It tolerates mild habitat disturbance, and is a reasonably common furnariid throughout its range.

[*Margarornis squamiger perlatus*,

Zamora-Chinchipe,  
Ecuador.  
Photo: Doug Wechsler/  
VIREO]

cies living in some of the coldest, hottest, driest, wettest and saltiest habitats colonized by any species in the huge order of Passeriformes.

The highest number of syntopic furnariids occurs in lowland tropical forest. *Terra firme* forest in Amazonia usually has 10-17 syntopic species. Transitional forest in western Amazonia typically has 12-14, with a taxonomic composition similar to that of *terra firme*. Usually ten to twelve ovenbird species are found in the humid forests of lowland south-eastern Brazil. Central American lowland tropical forest, on the other hand, may harbour only three to six, reflecting the rapid northward decline in ovenbird diversity. In the Andes, lower montane forests at, say, 1500 m can support 10-15 syntopic furnariids, depending on latitude, and are thus as rich as lowland localities, whereas high-elevation cloudforest, at around 3000 m, may have only three to seven, again depending on latitude. Deciduous forests of central and southern Bolivia hold an average of five or six species of ovenbird. Although the species richness of ovenbirds is drier, colder or more open habitats of the Neotropics may not be so high as that in humid tropical forest, ovenbirds may form a much higher proportion of the avifauna in the former biotopes. F. Vuilleumier's 1985 compilation of the avifaunas of extreme southern South America indicates that *Nothofagus* forest, for example, may have only three species of furnariid, but these can represent more than 15% of the true forest species. In the Andes, rocky slopes with scrub or *puna* grassland may support no more than four to six ovenbird species, yet this total could represent 25% of the local avifauna.

Within the Furnariidae, many genera share patterns of habitat association, which in turn are related to biogeography. For example, *Geositta*, *Upucerthia*, *Cinclodes* and *Asthenes* are found primarily in open non-forested habitats of the high Andes and Patagonian regions, with a few species, such as the Campo Miner, the Long-tailed Cinclodes and the Cipo Canastero, representing minor "outposts" farther north-east in the subtropical southern lowlands. Similarly, although *Furnarius* and *Phacellodomus* are primarily lowland genera of semi-open habitats of tropical and subtropical southern South America, a few taxa live in similar habitats farther north-west, especially in the Marañón Valley and the *llanos* region; these are the nominate race and the race *cinnamomeus* of the Pale-legged Hornero (*Furnarius leucopus*), subspecies *inornatus*, *castilloi* and *peruvianus* of the Rufous-

fronted Thornbird, and the monotypic Chestnut-backed Thornbird (*Phacellodomus dorsalis*). The three genera *Margarornis*, *Pseudocolaptes* and *Thripadectes* are restricted to humid montane forest of the Andes and the highlands of Costa Rica and western Panama. *Anabacerthia* is similar, but has a representative in montane areas of south-eastern South America. Four genera, *Philydor*, *Automolus*, *Sclerurus* and *Xenops*, are confined mainly to lowland tropical forest of Central America, Amazonia and the Atlantic Forest region. In contrast to the rest of the family, the genera *Synallaxis* and *Cranioleuca* are extremely broad in their habitat and biogeographical distributions.

In general, many members of Furnariidae show a strong tendency for specialization on habitats of unusual vegetation structure. Thus, several members of the family represent some of the most severe examples of habitat restriction among birds. The Point-tailed Palmcreeper is completely confined to groves of palm trees, mainly of the genus *Mauritia*. As these groves can be remarkably isolated from one another, and sometimes remarkably small, the palmcreeper presumably has excellent dispersal abilities that allow individuals, most likely independent young, to colonize isolated habitat clumps, perhaps then spending their entire lives within that clump. The vigour with which a pair of palmcreepers responds to tape playback suggests that these palm groves, often scarce, are tenaciously defended against prospecting individuals. The Araucaria Tit-spinetail is likewise restricted to a single species of tree, *Araucaria angustifolia*. Although this tree is more widespread and continuously distributed within its range than are the palms required by the Point-tailed Palmcreeper, the degree to which the Araucaria Tit-spinetail is restricted to that tree species is at least as dramatic. As a further example, the recently discovered Cipo Canastero is confined to a particular scrubby habitat found only around isolated rocky outcrops. Its global population must, therefore, be remarkably small, for the total area of such habitat, known as "*campo rupestre*", is minuscule in comparison with most habitat types.

The Furnariidae are particularly prominent as habitat specialists along the gradient of successional vegetation on river islands and some borders of major rivers in Amazonia. The various stages of succession, from open beaches to, ultimately, tall forest that is seasonally flooded, in general have an avifauna that shares few species with adjacent *terra firme* tropical forests. G. H.

Probing the nodes of bamboo plants in search of arthropods is one of the primary foraging methods of the **White-collared Foliage-gleaner**.

This species, which is restricted to the montane evergreen components of the Atlantic Forest of south-east Brazil, is strongly associated with bamboo thickets. It is an acrobatic feeder, mostly in the middle storey, and often climbs vertical stems and hangs upside-down as it forages. It obtains its invertebrate food by gleaning and probing along branches and among green and dead leaves.

The heavy, sharp bill of this furnariid is distinctive because of the straight culmen and sharply upturned lower mandible, and is occasionally used by the bird to hammer holes in bamboo stems to uncover prey.

A preference for bamboo is not uncommon within the ovenbird family.

At least three furnariid species are found exclusively within lowland *Guadua* bamboo thickets, and several others, including the one illustrated here, exhibit strong associations with bamboo habitat and are probably dependent on it. Studies have demonstrated, for example, that over 80% of the foraging activity of the White-collared Foliage-gleaner is directed at finding prey in bamboo plants. This ovenbird, incidentally, was formerly the sole member of the genus *Anabazenops*, but it has now been joined by the reclassified Dusky-cheeked Foliage-gleaner (*A. dorsalis*), which was previously treated as one of the *Automolus* foliage-gleaners.

[*Anabazenops fuscus*,  
Itatiaia National Park,  
Rio de Janeiro, Brazil.  
Photo: Edson Endrigo]

Rosenberg studied the birds of the early-successional stages on river islands in Peru. The furnariids that he considered obligate specialists on this habitat were the Pale-billed (*Furnarius torridus*) and Lesser Horneros (*Furnarius minor*), the White-bellied Spinetail (*Synallaxis propinqua*), Parker's Spinetail and the Red-and-white Spinetail. The White-bellied Spinetail is restricted to the earliest stage, a scrubby band of vegetation dominated by the willow-like shrub *Tessaria*. The Lesser Hornero, too, is found there, but it also occurs in the understorey of *Cecropia* woodland. Parker's Spinetail is most common in the early-successional scrub, but also ranges into *Cecropia* forest. The other two species were rare or absent at Rosenberg's primary study site. The Red-and-white Spinetail is highly restricted to the margins of oxbow lakes bordered by brush and grass, whereas the Pale-billed Hornero is found on older islands in *Cecropia* forest, mainly at edges. M. Cohn-Haft and Whitney have recently discovered that the Scaled Spinetail (*Cranioleuca muelleri*) is restricted to tall *várzea* forest.

The reason why the Furnariidae are so well represented among the Amazonian riverine-habitat specialists is presumably that the family has many species restricted to tropical water-edge habitats in general, thereby providing a large pool of candidates for such specialization. The Amazonian taxa usually have sister-species that are also associated to some degree with aquatic or water-influenced habitats, but have much wider distributions. For example, the Red-and-white Spinetail's sister-species is the much more widespread Yellow-chinned Spinetail of tropical marshes, and that of Parker's Spinetail is the far more widespread Rusty-backed Spinetail of riverine scrub and other water-edge vegetation. The Lesser and Pale-billed Horneros may both have shared a common ancestor with the Pale-legged Hornero, a more widely distributed species. The Scaled Spinetail's closest relative is presumably the Speckled Spinetail, also of *várzea* forests in Amazonia. In the case of the White-bellied Spinetail, however, the sister-species in *Synallaxis* is not certain.

Specialization on bamboo thickets, as illuminated by Parker and quantified mainly by Kratter, is a feature of many Neotropical bird species, and the Furnariidae are well represented among the bamboo specialists. The Peruvian Recurvebill (*Simoxenops ucayalae*), the Dusky-cheeked Foliage-gleaner and the Brown-rumped Foliage-gleaner are found only in or near *Guadua* bam-

boo thickets or, locally, in structurally similar *Gynerium* cane thickets. Other ovenbird species are strongly associated with thickets of bamboo, either *Guadua* in the lowlands or *Chusquea* in the mountains, but may not be restricted to them; examples include Des Murs's Wiretail, the Itatiaia Thistletail, the Rufous-capped (*Synallaxis ruficapilla*), Apurimac, Rufous, Cabanis's (*Synallaxis cabanisi*), White-browed and Light-crowned Spinetails (*Cranioleuca albiceps*), the Chestnut-crowned (*Automolus rufipileatus*), Rufous-necked and White-collared Foliage-gleaners, and the Striped and Flammulated Treehunters.

Parker, Fjeldså and colleagues have shown that the *Polylepis* woodlands of the high Andes have many bird species restricted to them. Surprisingly few, however, are ovenbirds, given the family's propensity for narrow habitat restriction. The Royal Cinclodes and the White-browed Tit-spinetail (*Leptasthenura xenothorax*) are the only furnariids known to be strict *Polylepis* habitat specialists. On the other hand, just as with bamboo, many furnariids are prominent members of the *Polylepis* avifauna, among them the Striated Earthcreeper (*Upucerthia serrana*), the Brown-capped (*Leptasthenura fuliginiceps*), Tawny, Rusty-crowned (*Leptasthenura pileata*), Streaked (*Leptasthenura striata*) and Andean Tit-spinetails (*Leptasthenura andicola*), the Creamy-crested (*Cranioleuca albicapilla*) and Baron's Spinetails, and the Line-fronted (*Asthenes urubambensis*) and Many-striped Canasteros (*Asthenes flammulata*), as well as the subspecies *arequipae* of the Creamy-breasted Canastero. Some of these ovenbirds may reach their highest densities in this habitat.

In many cases, it is suspected that a species must be restricted to a very narrowly distributed habitat, but the parameters that define this have yet to be discovered. The Hoary-throated Spinetail, for example, is known only from a small area of the upper Rio Branco, in extreme north Brazil and adjacent Guyana, where it is found in river-edge habitat. Such habitat, however, is essentially universal in Amazonia. Does the riverine habitat where the spinetail lives consist of some unusual plant association, found nowhere else? If not, what limits this species to that area? Similarly, the Orinoco Softtail is known only from one locality in the upper Rio Orinoco region; one wonders what is so unusual about that particular locality from the perspective of the softtail. The Russet-mantled Softtail is found at just a few localities in the Andes of northern Peru, generally in stunted timber-line forest;

**The Buff-tufted Cheek** specializes in rooting through dense epiphytic growth and associated debris in humid montane forest, where it targets, in particular, large bromeliads. These often contain little pools of water supporting communities of aquatic invertebrates and small vertebrates, such as frogs and salamanders, high in the canopy. Doubtless, it was from one of these that this individual obtained the frog that it is carrying back to its nest. This species exhibits strong sexual dimorphism in bill length, the female's bill being significantly the longer. This difference presumably confers an advantage in the exploitation of feeding resources, although the precise benefit remains a mystery.

[*Pseudocolaptes lawrencii lawrencii*, San Gerardo de Dota, San José, Costa Rica. Photo: Eduardo Libby]

Duetting and display by the **Brown Cachalote** probably achieve two aims, by affirming territorial ownership to possible rivals and also strengthening the bond between the partners. This species is thought to be monogamous, and mates sometimes stay together throughout the year. The pair-bond, however, appears to vary in duration, in some cases lasting for one season and in others representing a lifelong partnership. The sexes of the Brown Cachalote seem to have equal roles in incubation and brood-rearing. Although little or no detailed information exists for other furnariids, this pattern is thought to hold for the majority of the family.

[*Pseudoseisura lophotes*  
argentina,  
Las Lajitas,  
Salta, Argentina.

Photo: José & Adriana Calo]

it seems unaccountably absent from areas with similar habitat in the region, although, admittedly, this absence could be an artifact of poor sampling in the region. As a final example, the White-bellied Cinclodes appears to be confined to a relatively small area of high-elevation *puna* in central Peru, and is most frequently found in cushion-plant (*Distichia*) bogs. Boggy areas, however, are widespread in the *puna* zone of the Andes. What, if anything, is so different about the areas inhabited by this cinclodes?

Exposing of the prominent underwing pattern is a display method employed by a number of ovenbirds, most notably the miners (*Geositta*). For this **Scale-throated Earthcreeper** it probably serves a dual purpose by proclaiming territorial ownership and, further, attracting a mate and signalling a readiness to breed. This furnariid occurs in arid montane and lowland scrub and *puna* grassland. As with many avian species that inhabit arid regions, the breeding season will start with the commencement of the wet season. Persistent single-male song-perch singing or display has not been recorded for the Furnariidae, and this ties in with the belief that most members of the family are strictly monogamous.

Many of the Furnariidae, perhaps more than in any other passeriform family, are associated directly with water, from rocky intertidal pools to the edges of forest streams and to bogs in the high Andes. For example, most cinclodes species show affinities, to varying degrees, for water-edge habitats, some being totally restricted to littoral habitat; the Sharp-tailed Streamcreeper feeds almost exclusively along the edges of streams. At least three *Furnarius* ovenbirds, the Pale-legged, Pale-billed and Lesser Horneros, also regularly feed at the edges of rivers and streams. The Wren-like Rushbird, the Straight-billed and Curve-billed Reedhaunters, the Bay-capped Wren-spinetail and the Sulphur-throated Spinetail are mainly restricted to emergent vegetation in marshes, but the extent to which they take prey from the water, rather than from the vegetation, is unknown. Likewise, the two *Certhiaxis* spinetails are restricted to marsh and marsh-edge vegetation but, again, it is not known whether they obtain any prey from the water itself.

Similarly, it is possible that no other passeriform family contains so many species for which rocks are an essential habitat component, either as foraging substrates or as nest-sites. Although quantitative data are lacking, at least 16 furnariids are reported to glean rocks regularly or occasionally for food. These are the Creamy-rumped Miner (*Geositta isabellina*), the Bolivian Earthcreeper, the Royal, Bar-winged, Cordoba, Olog's, Surf, Seaside and Blackish Cinclodes, the Band-tailed Earthcreeper (*Eremobius phoenicurus*), the Crag Chilia (*Chilia melanura*), the Tawny and Plain-mantled Tit-spinetails, the Black-throated Thistletail (*Schizoeaca harterti*), the Cactus Canastero (*Asthenes cactorum*) and the Sharp-tailed Streamcreeper. Species known to use the crevices among or under rocks as nest-sites are the Rock (*Upucerthia andaeicola*), Straight-billed (*Upucerthia ruficauda*) and Chaco Earthcreepers, the Crag Chilia, the Long-tailed, Dark-bellied (*Cinclodes patagonicus*) and White-winged Cinclodes (*Cinclodes atacamensis*) in addition to five of the above-mentioned seven, the Brown-capped Tit-spinetail, the Cordilleran (*Asthenes modesta*), Sharp-billed (*Asthenes pyrrholeuca*) and Cipo Canasteros, the Spotted Barbtail and the Pearled Treerunner. Further fieldwork will certainly expand these lists. Of course, many additional species also occur in rocky habitats, but whether those species use rocks for anything other than singing perches has not been determined.

The incredible mud nest of the **Rufous Hornero** is just one of the many extraordinary nests built by a family of birds that display an incredible extravagance, diversity and complexity in nest architecture. The Rufous Hornero constructs its nest, using classic "adobe" techniques, from mud mixed with plant matter or dung. The result resembles an oven, and it is from this that the family has acquired its scientific and vernacular names. The globular structure is divided by an interior wall that partially separates the entrance area from the nest-chamber, inside which the eggs are laid on a crude cup of grass. The orientation of the entrance is variable, but often faces away from the prevailing wind. Nest design varies slightly, with some nests having two entrances and others having the entrance at the top. The large structure is usually conspicuously sited on a tree branch, post or roof, or even on the ground in bare areas. Building work can take up to three months or as little as two weeks, but in either case it involves the pair-members in an enormous expenditure of energy. Such a high-energy outlay in nest-building, however, is by no means unusual for the members of the Furnariidae. The resulting nests are some of the most outstanding protective shelters built by any of the world's birds, and probably explain why the ovenbird family is so well represented in the avifaunas of the harshest South American environments. Despite the amount of energy invested by ovenbirds in their nests, these are almost never reused by the birds that build them. Such well-built structures are, however, quickly taken over by a variety of other birds and animals in subsequent seasons.

### General Habits

Broadly speaking, the furnariids are not conspicuous in their behaviour. Although they often adopt acrobatic postures when perching, they are generally rather skulking birds and tend to be wary. As a consequence, their general behaviour is not well understood.

So far as is known, all members of the family are exclusively diurnal. Many ovenbirds typically roost in their nests outside the breeding season, and some species construct nests that seem to serve only as roosting sites. Others, however, such as the Rufous Hornero, the Rufous-breasted Spinetail and the Slaty Spinetail (*Synallaxis brachyura*), do not sleep in their nests, but in nearby dense vegetation. Some leaf-tossers have been found to roost in a vertical position at the bases of trees.

There are no published studies of the daily movement patterns of any ovenbird. Typically, the furnariids appear to be territorial throughout the year, and most are suspected of remaining completely within a relatively small territory. As with almost all birds, singing typically peaks near dawn. Many ovenbirds, however, continue to sing frequently during the day, but an absence of quantitative data prevents any sort of comparisons among species or regions, or between seasons. Nonetheless, a number of species, particularly foliage-gleaners in genera such as *Philydor* and *Syndactyla*, have seldom been recorded as singing after dawn; their similarity in this respect to the woodcreepers possibly provides another hint that the two are more closely related than is indicated by traditional taxonomy (see Systematics).

The majority of furnariids typically occur in pairs throughout the year. For many species, the pair-bond persists outside the breeding season and, in many cases, probably throughout life (see Breeding). After breeding, a few species become more gregarious, forming single-species flocks. Feeding parties of up to 40 Plain-mantled Tit-spinetails have been observed, as have flocks consisting of 12-15 Lark-like Brushrunners. Flocks of up to seven individuals of the latter species can be seen during the breeding season, but these are not much larger than would be expected if they consisted solely of family-members. Concentrations of Rufous-banded Miners (*Geositta rufipennis*) consisting of several hundred individuals have been recorded, but these may be aggregations of migrants (see Movements), rather than integrated

flocks. In contrast, several furnariids seem to become solitary after breeding; A. F. Skutch placed the Streak-breasted Treehunter, the Red-faced Spinetail (*Cranioleuca erythrops*) and the Buff-fronted Foliage-gleaner in this category. Observations of ovenbirds foraging as solitary individuals are numerous, but whether this indicates that pair-bonds do not exist at that time is unknown.

Although **Rufous Horneros** never reuse their nests, they often build new nests directly on top of old ones. It is possible that, for this species, nest-building is important in maintaining the lengthy, often lifelong pair-bond that exists, or perhaps the birds just wish to avoid the parasite burden that inevitably accumulates in previously occupied nests. In fact, many pairs routinely build more than one nest each year, before selecting one for final use. This level of effort appears to pay off in terms of reproductive success, which can be high, although, ironically for a species that nests in a "mini-oven", high temperatures can adversely affect breeding performance in some years.

[*Furnarius rufus albogularis*,  
São Paulo, Brazil.  
Photo: Fabio Colombini]

Nothing has been published on the breeding of the **Russet-mantled Foliage-gleaner**. The individual shown here was frequently entering and leaving this termitarium, and it is just possible that it had its own nest inside that of the termites. It was not seen to feed on the insects. Although little is known of the breeding behaviour of most members of the genus *Philydor*, the few species for which such information is available appear to use a hole in a bank, tree or wall for the nest, adding no more than a shallow lining.

[*Philydor dimidiatum baeri*,  
Das Emas National Park,  
Goiás, Brazil.  
Photo: Luiz Claudio Marigo]

In contrast to the oven-type nests of some furnariids, that of the **Creamy-breasted Canastero** is an amazing structure of thorny sticks, often sited in a tall, columnar cactus. The elongate, woven nest is impressively large, up to 4 m in length. It tapers at the top to incorporate a narrow entrance tube; this gives access to the inner chamber, which is spherical and completely lined with soft material. The thorny nature of the building materials, the situation in a prickly cactus and the narrowness of the entrance tube all combine to deter predators. Moreover, the nests are constructed so robustly that the dismantling of them is not a feasible option for a predator.

Many furnariids are characteristic members of mixed-species flocks, within which they are generally found in pairs or small family groups (see Food and Feeding). On the other hand, the ovenbirds are not well represented in the aggregations of birds that follow army-ant swarms.

Virtually nothing is recorded of the comfort behaviour of the members of this family, and as yet there is no indication that such behaviour differs in any substantive way from that of typical passerines. "Anting" has rarely been noted in the Furnariidae, but this may reflect a lack of published observations. Skutch has recorded anting by the Plain Xenops on several occasions.

Moreover, there is an almost complete absence of detailed data on displays and postures given by these birds. The cinclodes' wing-raising or wing-flapping display, accompanied by song, appears to be a territorial display, as do the flight songs of the miners. The partly concealed throat patch of many *Synallaxis* spinetails and *Asthenes* canasteros is revealed when the birds erect their throat feathers, and the function of these displays is interpreted as the maintenance of pair-bonds. In response to song playback, some foliage-gleaners and the tuftedcheeks flare their throat feathers. Ovenbirds in a number of genera raise the crown feathers in what could perhaps be interpreted as an agonistic dis-

The domed, thorny stick nests of some ovenbirds are never reused by the species that constructs them. They are, however, so well built and secure that they are regularly appropriated in subsequent seasons by other birds, including other furnariid species. This **Plain-mantled Tit-spinetail** has taken over what is probably an old canastero (*Asthenes*) nest, inside which it will have placed its own simple small cup of twigs, hair and feathers. Plain-mantled Tit-spinetails also hide their nests in any other suitable cavities, such as holes in trees and cacti and crevices in rocks and buildings.

The **White-throated Cachalote** builds an impressive stick nest, over a metre long and 50 cm across, by weaving together thorny sticks around a central breeding chamber. It builds a new nest each year, but often in the same location, leading to large amalgamations in favoured trees. This furnariid occurs in the arid lowlands of west-central Argentina. In some other bird families, one mechanism for ensuring reproductive success in similar harsh environments is to enlist the previous year's young as "nest-helpers". There is little evidence that this occurs among the ovenbirds, although it has been noted for the recently discovered **Pink-legged Graveteiro** (*Acrobatornis fonsecai*) and may also occur in the **White-throated Cachalote**.

play, but a great deal of research is needed before this interpretation is confirmed or negated. In general, little is known of the behaviour of furnariids in aggressive interactions.

### Voice

Although many ovenbirds are known for their loud songs and frequent singing, pleasing melody is not their forte. Moreover, their voices are remarkably homogeneous for such a large group. One could perhaps randomly scramble the published epithets of "dry",

"harsh" and "shrill", "accelerating" or "decelerating", "ascending" or "descending", and "trill" or "series of notes", and provide a passable description of the primary vocalization of the vast majority of species. For most furnariids that are more than about 15 cm in length, one could also add "loud" to the description. A theme in the songs of many ovenbirds is a series of slower, emphatic notes at the beginning or end of the main part of the song.

The low degree of variation among the songs of the various furnariids allows an observer familiar with the voices of just a few genera to identify most of the unfamiliar species immediately as furnariids. The exception to the non-melodious reputa-

Even among ovenbirds the well-studied nest of the **Rufous-fronted Thornbird** is a marvel of architecture. Built with carefully interlocked thorny sticks, some over 50 cm long, the massive structure, 2.5 m in length and up to 1 m across, hangs from a tree branch; it is initiated on a horizontal branch, but its weight causes the branch to bend. Riddled with entrance tunnels, the nest has up to nine main chambers and several antechambers. The eggs are placed in the lowest chamber. Incredibly, the interior is decorated with a lining of bark, hair, feathers and reptile skins.

tion of the family is the genus *Sclerurus*, the whistled songs of which are often considered melodious, or, at the least, an "improvement" over the harshness or buzziness so characteristic of the family's vocalizations as a whole.

Unfortunately, not a single species of ovenbird has been studied thoroughly in terms of vocal repertoire, functions of various vocalizations, sexual differences, or ontogeny of vocal development. Geographical variation has been quantified, over the greater part of the respective ranges, for only three species, the Olive-backed Foliage-gleaner (*Automolus infuscatus*), the Rusty-backed Spinetail and Parker's Spinetail, all by K. J. Zimmer, and C. Lindell has studied that of the Pale-breasted Spinetail over a portion of its range. For many species no archived recording exists, and for a few not even qualitative descriptions of either the song or the calls, or both, are available. What can be said about the vocalizations of this family is, therefore, greatly restricted by a near-total lack of formal studies, and most of what follows must be regarded as tentative.

It may be predicted that for the Furnariidae, as suboscines, the primary songs of all species are inherited, not learnt, and one would also expect relatively simple songs and small repertoires to be the rule. Although this prediction appears, on the surface, to be generally borne out, several exceptions are noteworthy. In some genera, such as *Furnarius*, *Pseudoseisura* and *Phacellodomus*, the existence of long, complex and seemingly variable duets seems unusual for suboscines. In others, the primary vocalizations of some or all species are rather variable and difficult to define. In the case of many miners, cinclodes and tit-spinetails, for example, the presumed songs of a single individual seem to vary greatly

in length and intensity. Further, it appears that, for the majority of species in many genera, the length of the song is not fixed, but is rather variable both among and within individuals.

Furnariid songs are rather simple in structure, in general consisting of a series of similar notes that usually span a relatively broad frequency range, thereby sounding harsh or buzzy rather than clear or whistled. The series may accelerate or decelerate, and rise or fall in pitch, but the notes themselves are relatively similar in "shape". Although documentation is generally lacking, astute listeners hear differences between the voices of the sexes, in many species emphasized by frequent duetting.

What actually constitutes the "song" is not always entirely clear. In the *Synallaxis* spinetails, the primary vocalization is typically a series of two to four notes or a short chatter, and this is repeated frequently, in fact nearly constantly, in turn by the members of a foraging pair. Thus, in terms of frequency, complexity and apparent function, these vocalizations are more like contact calls than like typical songs. Furthermore, some *Synallaxis* spinetails have been heard on rare occasions to give longer, seemingly more complex vocalizations, such as during throat-flaring displays, and it is possible therefore that these are the true songs, but are rarely given. Nevertheless, P. Schwartz, a pioneer of the study of tropical bird voices, reasoned that the shorter vocalizations should be considered as songs. In order to illustrate how frequently these short "songs" of *Synallaxis* are delivered, Skutch counted them: on one occasion, a Pale-breasted Spinetail in Costa Rica delivered its two-noted songs at the rate of 36-41 per minute for a period of 35 minutes, producing a total of roughly 1300 songs.

Although formal studies are non-existent, ovenbirds that are permanent residents at tropical and subtropical latitudes appear to sing throughout the year. Some of those living in far southern latitudes, at high elevations and in highly seasonal habitats presumably exhibit seasonality in singing, but relevant information is absent. Intensity of singing typically reaches a peak near dawn, but many ovenbirds continue to sing frequently during the day (see General Habits).

### Food and Feeding

Few other bird families of comparable species richness have diets so restricted to invertebrates, primarily arthropods. An almost complete absence of quantitative analyses, however, prevents any synthesis of the relative frequencies of types of arthropod taken by furnariids. The insect orders most commonly detected in inspections of stomach contents are generally Orthoptera, Blattodea and Coleoptera, and larval Lepidoptera; Diptera, and Hymenoptera other than ants, seem to be particularly uncommon, which is not surprising in view of the virtual absence of aerial foraging by this family. Ants, on the other hand, not generally a major dietary item of most birds, are suspiciously over-represented in the stomachs of a few species, especially the Lark-like Brushrunner and the Rufous Hornero.

The genus *Cinclodes*, with three species restricted to aquatic habitats, and the rest frequently associated with shorelines, is the only one in which non-arthropod invertebrates have been found to be major components of the diet. Studies by A. H. Beltzer have also shown that molluscs are a major food item of populations of the Bar-winged Cinclodes living in aquatic habitats. The diets of the maritime cinclodes, dominated by intertidal invertebrates, are closer to those of shorebirds of the family Scolopacidae than to those of other passerine birds. Although the Surf Cinclodes (and presumably also the Seaside Cinclodes) lacks the enlarged salt gland found in many birds with a high intake of salt-water prey, it does have an enlarged Harderian gland, the viscous secretion of which evidently protects the eye from salt water.

Vertebrates have been recorded as being taken by a number of the larger furnariids, mainly the treehunters in the genus *Thripadectes*. Small frogs and lizards are the main vertebrates eaten, and no mammals or birds have yet been reported as prey items. Bird eggs are sometimes consumed by the Brown Cachalote.

It is worth pointing out that ovenbirds frequently use a foot to hold down prey items against a branch or the ground (see

*Illustrating the huge diversity in the nests of this family, that of the Red-eyed Thornbird is a long, "boot-shaped" structure of thorny twigs, suspended from the tip of a tree branch, with the entrance low down.*

*The entrance connects to a tunnel leading to the inner chamber and other ancillary chambers, all of which are decorated with material such as hair and feathers. These splendid nests are often usurped by other species.*

*The Red-eyed Thornbird is restricted to south-eastern Brazil, where its two subspecies have very recently been discovered to occur sympatrically and are presumably, therefore, separate species. The two appear to have different habitat preferences, with one found in evergreen forest and secondary woodland and the other favouring wooded habitats associated with wetlands. The large stick nests of certain ovenbirds have been shown to be interesting micro-habitats in their own right, supporting diverse communities of invertebrates.*

[*Phacellodomus erythrophthalmus erythrophthalmus*, Penedo, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Despite its relatively small size, the **Streak-fronted**

**Thornbird** builds an enormous nest very much in the style of those of other members of the genus *Phacellodomus*.

The greatly elongated structure is constructed from carefully woven thorny sticks, and can be up to 150 cm long and 50 cm wide. These birds are most easily observed in the vicinity of their nests, and this must, to a certain extent, reflect the amount of time that they devote to construction and maintenance of these massive structures.

Their nests are often situated, as here, such that they hang over a ravine or a cliff, but they are also placed in the open in a low tree or bush, or even on a utility pole.

The entrance hole is at the side of the nest and leads, via a short tunnel,

to the interior nest-chamber, which is lined with plant material, hair and feathers. **Streak-fronted Thornbirds** are resident in the Andes, from southern Peru to north-west Argentina, and occur in montane scrub and adjacent farmland, usually in semi-arid areas with cactus scrub.

They usually forage in pairs, gleaning and probing for arthropods at all levels from the ground up to the canopy.

The species appears to tolerate moderate habitat disturbance and human presence, even being frequent around houses.

[*Phacellodomus striaticeps striaticeps*,  
Laguna Larga,  
Jujuy, Argentina.  
Photo: Andy & Gill Swash]

A further example of the extraordinary nests built by the Furnariidae is provided by the **Wren-like Rushbird**. The nest of this species, built in aquatic vegetation, is an untidy conglomeration woven from wet grass and other plant material cemented together with wet mud, which quickly dries to give a strong, hard outer shell. The egg-chamber in the interior is lined with softer material. The whole structure is supported by several stems of the dominant emergent plant, which are firmly drawn into the structure and cemented in place. It usually sits about 80 cm clear of the water's surface. The side entrance is protected by an "awning", and it is this aspect of nest architecture that suggests a possible relationship between the Wren-like Rushbird and the two marsh-dwelling reedhaunters of the genera *Limnornis* and *Limnortyx*. Another similarity, at least with the Curve-billed Reedhaunter (*Limnornis curvirostris*), is that the eggs of the rushbird are blue-green; this is unusual within the ovenbird family, the members of which lay eggs that are mostly white or whitish. The relationships of this species, however, are unclear and are further confounded by plumage similarities with the rayaditos (*Aphrastura*). Like many temperate-zone furnariids, the Wren-like Rushbird is busy attending nests in the austral spring. Although not considered to be threatened, it depends on fragile wetland ecosystems and has, as all such species, suffered declines as a result of human activities. Locally, populations of the Wren-like Rushbird have been, and continue to be, adversely affected by drainage and by the lowering of water tables caused by such activities as plantation forestry and agriculture.

Cahuil, Cardenal Caro,  
Región VI, Chile.  
Photo: Manuel Marín]

Morphological Aspects). The use of the feet for holding food is not widespread among passerine birds.

Vegetable matter has been infrequently recorded as food. Seeds are evidently an important or, at least, a regular part of the diet of some miners, especially the Rufous-banded Miner, and of the Russet-bellied Spinetail (*Synallaxis zimmeri*). Seeds have been found occasionally in the stomachs of a few other species, among them the Crag Chilia, several *Cinclodes*, some horneros, some canasteros, some earthcreepers and the Firewood-gatherer. Fruit has been recorded with certainty in the diets of only a few species: these are the Itatiaia Spinetail, the Rufous-breasted Spinetail, the Orange-fronted Plushcrown, the Grey-crested Cachalote (*Pseudoseisura unirufa*), the Brown Cachalote and the Black-tailed Leaf-tosser (*Sclerurus caudacutus*). Otherwise, seeds that may have come from unidentified fruit have been noted in the stomachs of a few individuals of other furnariids, namely several *Schizoeaca* thistletails and some *Synallaxis* spinetails. No examples of nectar-feeding have been reported; although the Orange-fronted Plushcrown has been seen to feed at flowers, it is not known whether it was foraging for insects or taking nectar.

The vast majority of the family's members search for cryptic or concealed arthropods on such substrates as bark, epiphytic vegetation on branches, curled dead leaves and debris suspended above the ground, leaf litter on the ground, or bare ground. Many species also search green foliage, but fewer than one might expect in such a large, mostly insectivorous family. A few excavate for invertebrates, either in branches, as with, for instance, the recurvebills and the xenops species, or in the ground, as is the case with the *Upucerthia* earthcreepers.

Many furnariids are considered among the most specialized feeders in the Passeriformes in terms of substrate specificity. For example, several species are specialized "dead-leaf searchers", with more than 75-90% of their recorded foraging manoeuvres being directed at dead leaves, either single ones or clusters, suspended above ground. Although sample sizes are still small in some cases, the following seven species are considered to be "dead-leaf specialists": the Speckled Spinetail, the Montane Foliage-gleaner (*Anabacerthia striaticollis*), the Rufous-tailed and Rufous-rumped Foliage-gleaners, and the Buff-throated, Olive-backed and Chestnut-crowned Foliage-gleaners. Several others are suspected of being at least as specialized, but further field-work is needed to confirm this. Numerous other furnariids frequently search dead leaves as part of their foraging behaviour, but are not so narrowly specialized; they include many or all species of *Cranioleuca*, *Thripophaga*, *Syndactyla* and *Thripadectes*, and some species of *Synallaxis*. Studies by R. Greenberg,

J. Gradwohl and K. V. Rosenberg have shown that these dead leaves provide diurnal refuges for many, primarily nocturnal, arthropods. Rosenberg found that curled dead leaves harbour many cockroaches (Blattodea), katydids (Tettigoniidae), spiders and small beetles, and that, the larger the leaf, the bigger and the more numerous are the arthropods inside them. Dead leaves held three to four times as many arthropods per leaf as did live leaves, with the largest dead leaves, 30 cm or more in length, averaging more than one arthropod per leaf. It is no wonder that many species of ovenbird seek prey in such places.

Another type of substrate specialization is the dedicated searching of epiphytic vegetation for concealed animal prey. The studies carried out by Sillett have quantified the degree of such specialization shown by birds in montane Costa Rica, where Sillett found that the Buffy Tuftedcheek and the Ruddy Treerunner directed over 95% of their searches at epiphytic vegetation. The tuftedcheek concentrates on tank bromeliads, whereas the treerunner searches primarily the layer of "moss", in reality consisting mainly of bryophytes and foliose lichens, attached to and suspended from branches. Although sample sizes are smaller, similar foraging behaviour has been found to be practised also by the Streaked Tuftedcheek and the Pearled Treerunner, the Andean counterparts of the two Costa Rican species, and is suspected for the other two treerunners, the Fulvous-dotted (*Margarornis stellatus*) and Beautiful Treerunners. In addition, the Pale-browed Treehunter evidently searches primarily epiphytic vegetation in the Atlantic Forest region. Many other ovenbirds regularly search large epiphytes but are not so specialized, examples of which include the Striped Woodhaunter, the Rufous-necked Foliage-gleaner, the Bolivian Recurvebill, the Black-capped Foliage-gleaner (*Philydor atricapillus*) and some of the *Thripadectes* treehunters. A large number of others persistently to regularly examine the layers or clumps of epiphytic bryophytes and lichens on tree branches, but the extent to which they exploit this foraging substrate has not yet been quantified or, if it has, does not indicate any specialization on this substrate. Examples include many species of *Leptasthenura*, *Cranioleuca*, *Syndactyla* and *Thripadectes*, both rayaditos, the Line-fronted Canastero, the Streak-fronted Thornbird, the Spectacled Prickletail, the Pink-legged Graveteiro, the Rusty-winged, Spotted and Roraiman Barbtails, the Beautiful Treerunner, the Scaly-throated, Montane and Buff-fronted Foliage-gleaners, the Sharp-billed Treehunter and the Rufous-tailed Xenops. The Critically endangered Royal Cinclodes frequently probes and gleans mosses and lichens that encrust rocks, as also does the commoner Sharp-tailed Streamcreeper.

Many furnariids use burrows for nesting, as typified by the miners. The **Coastal Miner** often nests at the end of a 2-m tunnel in level, sandy ground, but it is not clear whether the birds excavate the burrows themselves, as do some miners, or appropriate those dug by other animals. Coastal Miners live in Peru, where they frequent sparsely vegetated sandy coastal desert and arid scrub, as well as a local habitat, known as lomas, that consists of rather barren low hills with meagre precipitation from the low clouds that develop when moist sea-air currents meet the desert hills.

[*Geositta peruviana* rostrata and nest-burrow, Paracas, Ica, Peru. Photos: L. Batten/FLPA]

The **White-eyed Foliage-gleaner** is typical of the genus *Automolus* in that its nest is placed at the end of a tunnel that the birds themselves have excavated into a vertical earth bank. The horizontal tunnel, about 60 cm in length, terminates in the nest-chamber, which contains a shallow cup of plant material and hair that holds the clutch of 3-4 eggs. As so little is known about the breeding biology of this large family, field observers should be aware that many of the nests of those species inhabiting humid forest, including those of several *Automolus* foliage-gleaners, remain undescribed.

[*Automolus leucophthalmus sulphurascens*, Linhares, Espírito Santo, Brazil. Photo: Edson Endrigo]

Almost certainly the most specialized of all furnariids is the Point-tailed Palmcreeper, which seeks food exclusively in the fronds and foliage of palm trees, and is evidently the only Neotropical bird species thus specialized. The Cinnamon-rumped Foliage-gleaner (*Philydor pyrrhodes*) is frequently found in or near palms, and often searches fronds and the dead leaves trapped in palms, but it is less of a specialist than is the palmcreeper.

These types of foraging substrate are generally not available on a year-round basis at most temperate latitudes. In such regions, dead leaves suspended above the ground are normally found in quantities only in autumn and early winter, tank bromeliads and palms are absent, and extensive epiphytic growth is unusual. The exceptional species richness for which tropical latitudes are renowned can be explained, therefore, at least in part, by the addition to the bird community of such foraging specialists, many of them in the Furnariidae.

Many species of ovenbird are characteristic members of mixed-species foraging flocks, in habitats ranging from Amazonian forest to timber-line scrub and to desert washes. Most species in the genera *Leptasthenura*, *Cranioleuca*, *Margarornis*, *Pseudocolaptes*, *Anabacerthia*, *Philydor*, *Automolus* and *Xenops* are "professional" members of mixed-species flocks, but the only ones suspected of being "nuclear species" in such flocks are some of the *Leptasthenura* tit-spinetails. Within mixed-species flocks, ovenbirds are normally found in pairs or as family groups. Among furnariids of wooded habitats, only the terrestrial feeders of the genera *Furnarius*, *Sclerurus* and *Lochmias*, and some of the near-terrestrial *Synallaxis* spinetails of dense undergrowth, forage typically as single individuals or pairs.

Seasonal variation in social organization during foraging is unusual. Outside the breeding season, a few species form single-species flocks, whereas several others appear to become more solitary at that time (see General Habits).

In contrast to their frequent presence in mixed-species flocks, furnariids are not well represented in the concentrations of birds that regularly follow swarms of army ants to capture prey fleeing from the ants. E. O. Willis and others have noted many species of ovenbird as rare or occasional attendants at such swarms, but no one species of furnariid has been reported to be even a regular ant-follower, despite the abundance of ovenbirds in the undergrowth of forests harbouring army ants. This lack of exploitation

of army ants is perhaps due to the overwhelming tendency of the Furnariidae to be "substrate-orientated", dedicated to searching or manipulating specific substrates to reveal generally concealed prey, as opposed to "target-orientated", focusing on the direct, visual location of exposed prey items. The latter strategy is typical of many antbirds in Thamnophilidae, the family most famous for its association with army ants (see page 495), and is also used by the several habitual ant-followers among the woodcreepers, which are close relatives of the ovenbirds (see Systematics).

## Breeding

For the vast majority of species in the Furnariidae, data on breeding are lacking. Furthermore, the species for which some details are known are not randomly distributed but, instead, are strongly clustered in two geographical regions, namely Costa Rica and eastern Argentina. In the former of those countries, this information is, of course, the result of the decades of fieldwork carried out by the indomitable Skutch; the Argentine data result primarily from the fieldwork of S. Narosky, M. de la Peña, R. Fraga, P. Mason, and A. and P. Nores. In addition, B. T. Thomas, Lindell and Skutch have contributed important information on the Rufous-fronted Thornbird from work undertaken in the *llanos* region of Venezuela. Without the studies of these people, virtually nothing would be known about furnariid breeding biology.

Clearly, this concentration of fieldwork in so few areas leaves enormous gaps in knowledge for major biomes, where fundamental differences may exist because of underlying differences in temperature and rainfall, and in the seasonality of resources. Most dramatically, virtually nothing is known about the breeding biology of any ovenbird in Amazonia, the Atlantic Forest region of south-eastern South America and the cloudforests of the Andes, nor of any furnariid inhabiting the drier parts of the interior Andes, whether low hot valleys or high-elevation *puna*.

Timing of breeding has been quantified for a few ovenbirds, primarily species from towards the latitudinal extremes and, therefore, the most seasonal habitats. The limited quantitative data, combined with anecdotal information for many species, reveal virtually no surprises. For example, all furnariids studied so far in southern South America breed mainly during the austral spring

Another burrow-nesting furnariid, the **Buff-breasted Earthcreeper**, usually chooses the vertical earth bank of an ephemeral watercourse in which to excavate, although it sometimes places its nest in a deep rock crevice. The tunnel is usually 70-100 cm long, and ends in a nest-chamber with a simple pad of grasses and feathers. The two eggs are generally laid at the beginning of the austral summer, from November. Because nest architecture is so varied within the Furnariidae, as well as being an indicator of taxonomic relationships, it is not surprising that it has been studied in some detail. These studies indicate that nesting in cavities is the primitive, ancestral condition of the ovenbird family, and that those taxa that have moved away from this method have "compensated" by building nests that are always covered in some way. Examples of the latter include the mud nests of the horneros (*Furnarius*) and the domed stick nests of the thornbirds (*Phacellodomus*) and canasteros (*Asthenes*). Such research, when applied to investigation of the systematic relationships among the various genera in the family, has supported many of the traditional groupings of the current sequence but has also raised a significant number of unanswered questions and new ideas. Examination of the cavity-nesters that build simple woven cups of plant material in the egg-chamber produces a clade that includes the genera *Upucerthia*, *Geositta*, *Cinclodes* and *Furnarius*, as well as a number of taxa from the "opposite" end of the traditional linear sequence, such as the *Philydor* foliage-gleaners and *Xenops*. Questions raised by such research are amenable to testing by use of genetic data.

and summer months, as would be expected for insectivorous species, and those studied in Middle America breed primarily near the onset of or during the wet season. Species living in arid and semi-arid areas also breed when expected, starting at the onset of the wet season. In Surinam, the marsh-nesting Yellow-chinned Spinetail may breed in all months of the year. Where data are lacking, unfortunately, is from low-latitude Amazonian forest and Andean cloudforest, where furnariid species richness is highest, where predictions are less clear-cut, and where the timing of the breeding seasons of birds in general is poorly known.

Discounting replacement clutches, it is apparently unusual among the Furnariidae for more than one breeding attempt to be made in a single season. True second nestings have been noted for pairs of Common Miners, Rufous Horneros, White-whiskered Spinetails, Dusky-tailed Canasteros (*Asthenes humicola*), Rufous-fronted Thornbirds and Scaly-throated Leaf-tossers (*Sclerurus guatemalensis*). Further study may reveal that double-brooding is much more frequent than is currently realized.

Information relating to seasonal gonadal enlargement is considered to be generally of limited value in determining the breeding seasons of furnariids. This is because it is uncertain to what degree such data actually track the timing of breeding by ovenbirds, which are typically paired and territorial throughout the year, and often begin work on their complex nests many months before breeding proper begins. Without comparisons with gonad size during the breeding period itself, therefore, "enlarged gonads", at least in males, may indicate only that the bird is paired, defending a territory, and perhaps building a nest long in advance of eggs being laid. In the case of females, enlarged ova or ruptured follicles are, of course, convincing evidence for breeding, but it is usually impossible to determine whether broad statements along the lines of "enlarged gonads" include such higher-quality evidence. Likewise, nest-building is not a particularly good indicator of timing of breeding by ovenbirds because, as mentioned above, this may begin months in advance of the actual breeding attempt itself, and in some species goes on to a limited degree all year round, which is not surprising when one considers the complexity of many ovenbird nests.

The Furnariidae are as "dull" in terms of social-system diversity as they are in plumage coloration (see Morphological Aspects). With the caveat that studies of marked populations are almost nonexistent, all indications are that monogamy is by far the most common, if not the only, mating system in the family. The high proportion of species that characteristically feed in pairs also suggests that genetic monogamy, rather than just social monogamy, may be predominant. A typical response of many species to the playback of their songs is that both members of a pair react aggres-

sively, often with vigorous duets. Furthermore, these pair-bonds are known, or are suspected, to persist beyond breeding in many species, such as the Rufous Hornero, the Slaty Spinetail, the Firewood-gatherer, the Ruddy Treerunner and the Brown Cachalote, although a few appear to become solitary after the breeding season ends (see General Habits). Despite a lack of hard data, many furnariids are suspected of having lifelong pair-bonds. Fraga found that some individuals of the Rufous Hornero remained paired to one another for up to four years, whereas other individuals switched mates even if the pre-existing one was still present. Nores and Nores found a similar flexibility in the Brown Cachalote, with some partners remaining together for at least four years and others switching mates within a single breeding season. For the only furnariids that have been studied in sufficient depth, therefore, the duration of the pair-bond is flexible. Long-term ringing studies on other species are urgently needed to provide critical comparisons among and within species, genera and habitats.

Not a single case of polygyny or polyandry has been documented for any furnariid. Promiscuity seems particularly unlikely, given what is known of the natural history of the family as a whole. For example, no species has been suspected of forming leks, nor has persistent single-male song-perch singing been reported.

For only a few species has suspicion arisen that the social system is more complex than monogamy. Although groups of up to seven Lark-like Brushrunners are common during the breeding season, with somewhat larger flocks at other times (see General Habits), observations of this species at the nest have typically involved only pairs, although in one case it was suspected that more than one female had laid eggs in the same nest. The social unit of the Rufous-fronted Thornbird consists of a pair, with one or more additional individuals that sleep in separate chambers within the nest. It is strongly suspected that these "extra" birds are the young from previous broods. Careful studies by Thomas found that they did not contribute to the raising of the offspring, but only to defence against predators and, in a minor way, to nest maintenance; thus, they barely merit the label "nest helpers", which normally requires that help be directed towards the feeding of the young. However, a recent study in Brazil detected an instance of a helper feeding a nestling, which suggests that true helpers may be present in that population. Adding to the many oddities surrounding the Pink-legged Graveteiro, an individual in immature plumage was observed while feeding a begging juvenile, which was also being fed by adults. This species, not described until 1996, provides the first instance of true helping in the family; young graveteiros were also watched as they assisted in nest construction. Also, Zimmer and Whitaker found that, al-

Leaf-tossers represent another group of burrow-nesting ovenbirds. The **Rufous-breasted Leaf-tosser**, an adult of which is here leaving the nest after an incubation stint, excavates in earth banks and among the roots of fallen trees, or simply uses pre-existing holes. Very few data exist on incubation periods and hatching patterns of the Furnariidae. For a bird the size of this leaf-tosser, weighing 30-38 g, it is likely that incubation lasts for at least 20 days and that the sexes share incubation duties.

[*Sclerurus scansor scansor*, Serra dos Órgãos National Park, Rio de Janeiro, Brazil. Photo: Kristof Zyskowski/VIREO]

This **Thorn-tailed Rayadito** is ejecting unwanted plant matter from a suitable tree cavity, before lining it with carefully chosen twigs, grasses and feathers. This species will nest behind loose bark, as well as in any cavity in a tree or dead snag. It lives in central and southern Chile and adjacent parts of Argentina, where it frequents tall humid forest, usually of southern beech (*Nothofagus*). Interestingly, two of its three subspecies inhabit tussock grass and low shrubs on treeless offshore islands. The nest-site selection of these island birds must, therefore, differ from that of the nominate, mainland race, but details are unknown.

though most breeding territories of the Caatinga Cachalote (*Pseudoseisura cristata*) were defended by an adult pair, a substantial portion were defended by three or four birds in adult plumage, or by a pair of adults and a juvenile; in at least one case, all four adult-plumaged birds brought food to the nest. Finally, Ridgely observed four Orange-fronted Plushcrows as they attended two nests close to one another. This is another of those species for which small groups, presumably families, and including birds in subadult plumage, are the typical social unit. Perhaps this unusual furnariid also has an unusual social system.

Records of courtship feeding have been published for just three ovenbird species, the Pale-legged Hornero, the Rufous-fronted Thornbird and the Plain Xenops, but with only a single instance in each case. The scarcity of such records seems to re-

flect genuine rarity of this behaviour in the family. Allopreening by paired individuals has been noted only once, involving two Slaty Spinetails watched by Skutch.

Data on the roles of the sexes during breeding are few and suffer from small sample sizes. Bearing that in mind, the few existing studies suggest that, throughout the family, both members of the pair contribute to nest-building, incubation, and the feeding of nestlings and fledglings, but the absence of sexual plumage dimorphism (see Morphological Aspects) impedes determination of the relative contributions by each sex. Quantitative observations by Skutch on a small number of species, such as the Slaty Spinetail, the Buff-throated Foliage-gleaner, the Scaly-throated Leaf-tosser and the Plain Xenops, are consistent with the qualitative impressions of many ornithologists who are familiar

A good supply of wet mud is vital for all birds that build mud nests, including the **Crested Hornero**. This species uses wet mud and plant fibres to build a classic "adobe oven" nest in a conspicuous location. The nest is very similar to that of the Rufous Hornero (*Furnarius rufus*), but is slightly smaller. The Crested Hornero is fairly common in lowland Chaco and dry woodland, often near human habitation and clearings, in south-east Bolivia, western Paraguay and north-west Argentina.

[*Furnarius cristatus*,  
Joaquín V. González,  
Chaco, Argentina.  
Photo: Andy & Gill Swash]

**Rufous Horneros** and other *Furnarius* species that build mud nests use classic adobe construction techniques. Wet mud and fibrous material are mixed together and used to build up walls 3-5 cm thick; each layer is left to dry in the sun before the next is added. The resulting structure is very strong and can weigh 5 kg. Such nests, which litter the horneros' territories, are reused for nesting or roosting by a variety of birds, and also provide shelter for reptiles and small mammals. The engineering qualities of this simple building material and technique have been exploited by human builders around the world.

[*Furnarius rufus commersoni*, northern Pantanal, Mato Grosso, Brazil. Photos: Jean-Louis Klein & Marie-Luce Hubert/Bios]

with furnariid breeding biology, namely that the sex roles are roughly equal. This also accords with the conspicuous absence of strong sexual dimorphism in the family.

That both sexes incubate the eggs and feed the nestlings has been confirmed for seven species. These are the Common Miner, the Rufous Hornero, Pinto's (*Synallaxis infuscata*), Rufous-breasted and Slaty Spinetails, the Brown Cachalote and the Buff-throated Foliage-gleaner. In addition, male and female Scaly-throated Leaf-tossers share incubation, and both sexes of the Blackish Cinclodes, the Masafuera Rayadito, Streak-breasted

Treehunter and the Black-tailed Leaf-tosser are known to feed the chicks. Possible exceptions to the pattern are the Buffy Tuftedcheek and the Rufous-rumped Foliage-gleaner, for each of which only one nest has been studied. In both cases, only one parent was noted as attending the nest, and one may suspect that the same applies to the Buffy Tuftedcheek's sole congener, the Streaked Tuftedcheek.

A separate monograph could, and should, be written on the nests of the Furnariidae. Although the family is rather monotonous in most aspects of its life, it compensates for this in part

With a beak full of wet mud, this **Rufous Hornero** displays prominently on top of a nest under construction while its partner calls vigorously from the nest entrance. Pairs often display during the nest-building phase, 2-3 months long, of the breeding cycle, and this ritual may be an important part of courtship and also help to sustain the year-round pair-bond that exists in this species. Such visual and vocal signals, together with the conspicuous placement of the large nest, must also play a major part in the declaration of territorial ownership to nearby rivals.

[*Furnarius rufus commersoni*, Pantanal, Mato Grosso, Brazil. Photo: Günther Ziesler]

As its name suggests, the **Firewood-gatherer** is often seen carrying sticks as it tirelessly builds its large nest. The final structure, up to 2 m in length and invariably conspicuous, is usually placed low in an isolated bush or tree, often close to previous years' nests. This species uses various human artefacts, such as glass and string, to decorate the entrance hole and tunnel leading to the nest-chamber. It is also one of few ovenbirds known to be double-brooded, although, as breeding data are lacking for the vast majority of the family, this may be more common than is supposed. Equally unusual is the fact that the first-brood offspring occasionally help the parents to build the nest for the second brood.

[*Anumbius annumbi*,

through a diversity and complexity of nest types that is rivalled by no other bird family. The nests of some ovenbirds are so large that they must be the biggest or heaviest, in relation to the body size of the bird, of any in the Passeriformes. For example, a pair of Rufous Horneros, each partner weighing 50 g, may construct a nest that has a weight of 5 kg, one hundred times that of the bird itself. The total energy expended by the pair in collecting, transporting and moulding that amount of mud and straw is difficult to imagine. Ovenbird nests cannot rival those of some weavers (Ploceidae), but the large nests of the colonial

weavers are typically the result of the efforts of all colony-members, rather than the single-pair efforts of the ovenbirds. Furthermore, the branches used in many ovenbird nests are so big that they must represent the upper limit of what a bird can carry in its bill in terms of relative weight and bulk. In fact, in order to believe that the branches used by some furnariids are carried to the nest by the birds themselves, one has to witness the birds in the act of doing so. Scant evidence suggests that sticks weighing more than the individual bird itself are carried by means of a series of short flights.

Ovenbirds that build stick nests, such as this **Yellow-chinned Spinetail**, take great care in constructing them, and the resulting structures are extremely strong. A human can stand on some of the nests of the cachalotes (*Pseudoseisura*), for example, without damaging them. This structural strength, and the fact that thorny sticks are used in the construction, must deter even large mammalian predators from attempting to open up the nests. The Yellow-chinned Spinetail inhabits wetlands. Its nest measures about 40 x 30 cm, with a long curving entrance tunnel, and is usually low in vegetation, close to or over water.

Calo]

For nest-building, the **Grey-crested Cachalote** uses enormous sticks and small branches, some of which can be 60 cm in length. The result is a large structure typical of many of the stick-nesting ovenbirds. Interestingly, this species also incorporates other materials, such as bones, crab carapaces, large feathers and snail shells, into the structure, and decorates the interior chamber with bark and snakeskin. An extremely similar nest is built by the closely related *Caatinga Cachalote* (*Pseudoseisura cristata*), which was until recently regarded as conspecific with the Grey-crested Cachalote.

The complexity, durability and size of the nests of many furnariids naturally make them ideal shelters for other animals. The invertebrate faunas using ovenbird nests are impressive in their diversity and abundance. Many depend on the presence of the adult birds or nestlings for food, as is the case with blood-sucking Hemiptera such as *Psammolestes* and *Triatoma* and mites (Acarina), but many others use the nest structure primarily for shelter. The large stick nests of the Firewood-gatherer, the Rufous-fronted Thornbird and the Brown Cachalote can host hundreds of arthropods that use it for shelter, or that feed upon smaller arthropods sheltering therein, including beetles, cockroaches (Blattodea), spiders, pseudoscorpions (Pseudoscorpiones), millipedes (Diplopoda) and flies. Social wasps place their nests in abandoned thornbird nests, and sometimes in active ones, and honeybee colonies have been discovered in the old nests of Rufous Horneros.

Other birds regularly use abandoned ovenbird nests for nesting or roosting purposes. Mason found, for example, that old nests of the Rufous Hornero at his study site in Argentina become nest-sites for Tufted Tit-spinetails, White-rumped Swallows (*Tachycineta leucorrhoa*), Saffron Finches (*Sicalis flaveola*) and introduced House Sparrows (*Passer domesticus*). Other species noted as using Rufous Hornero nests are the White-winged Swallow (*Tachycineta albiventer*), the Brown-chested Martin (*Progne tapera*), the House Wren (*Troglodytes aedon*), the Chopi Blackbird (*Gnorimopsar chopi*), the Cattle Tyrant (*Machetornis rixosus*) and *Forpus* parrotlets, these last also frequently using nests of the Pale-legged Hornero in western Peru. Thomas, Lindell and Skutch found that Rufous-fronted Thornbirds nests are used by Saffron Finches, Cattle Tyrants, Piratic Flycatchers (*Legatus leucophaius*), Stripe-backed Wrens (*Campylorhynchus nuchalis*) and Blue-grey Tanagers (*Thraupis episcopus*) among others; these species may use old nests or unused chambers within an active nest. Although the presence of nest associates may result in aggressive interactions and occasional egg loss, Lindell found that active thornbird nests with avian nest associates were more successful than those without, presumably due to improved defence against predators. These researchers also found that the Troupial (*Icterus icterus*) regularly evicts the thornbirds, rather than waiting for the nest to be abandoned; Lindell found that of 76 observed thornbird nest failures 6 (8%) were caused by Troupials.

Brown-chested Martins and House Sparrows also occasionally succeed in evicting Rufous Horneros from their nests. The Bay-winged Cowbird (*Agelaioides badius*), an obligate nest-adopter, uses the nests of the Rufous-fronted Thornbird and the Firewood-gatherer. Other vertebrates, too, regularly use ovenbird nests. Several rodents, including species in the genera *Thomasomys*, *Proechimys* and *Oryzomys*, have been found roosting in ovenbird nests, but it is not known whether they usurped these or used abandoned ones. Lizards, small snakes and frogs sometimes shelter in the nests of the Rufous-fronted Thornbird.

At least some published information on nests is available for about 170, or over 70 %, of the 236 furnariid species. This figure, relatively high for a largely tropical-latitude family, is due in part to the relatively conspicuous nests of many species. Zyskowski and Prum undertook the mammoth task of compiling all published and unpublished data on nests of the Furnariidae, organizing the variation into characters, and analysing those characters by phylogenetic methods (see Systematics). This important analysis is a foundational paper for the biology of the Furnariidae, and also provides a model for the analysis of nest data. Much of what follows is taken directly from their 1999 paper. Zyskowski and Prum identified 24 "character states" that they used to score each species for which data were available, and these characters are outlined below. For several reasons, including the scarcity of data on the nest-building behaviour of many species, these features were restricted to the form of the nest itself, and took no account of the behaviour used in constructing it. For example, "burrows" were treated alike, regardless of whether they were excavated by the birds themselves or by other animals.

The adobe mud nests made by ovenbirds in the genus *Furnarius* are remarkable structures in terms of size, mass and architecture. Although this genus and its characteristic "adobe oven" nests provide both the English and the scientific names for the family, this nest type is in fact quite unusual in the family, being restricted to the one genus. Moreover, at least one species, the Wing-banded Hornero, evidently does not construct that type of nest, and another, the Pale-legged Hornero, may adopt nests of other birds. The walls of a *Furnarius* oven are made of mud mixed with plant material or dung, which becomes extremely hard when dry. One of the inner walls also folds inwards, divid-

The technique used by the **Wren-like Rushbird** to construct its nest is unique within the ovenbird family. The bird carefully weaves wet fibrous plant material into a domed structure and cements the fibres together with coatings of wet mud. The eggs are not laid until the nest dries and hardens. The variety of nests built by the members of the Furnariidae is staggering, but all fit neatly into three main categories: mud nests, cavity nests and domed nests. That of the Wren-like Rushbird falls into the last category, which is perhaps the most diverse grouping. Domed nests are constructed of plant material, often sticks, and occasionally have special architectural features. One such feature is the "awning" that the rushbird adds above the entrance hole of its nest. Other special features of domed nests include reinforcement, or "thatching", of the dome, as is carried out by some of the *Certhia* and *Synallaxis spinetails*; the construction of protruding entrance tubes, as, for example, by the *Red-shouldered Spinetail* (*Gyalophylax hellmayri*); and the great variety of interior layouts of the stick nests, with tunnels, varying numbers of chambers and antechambers, and often some degree of "decoration" with objects such as snakeskins and refuse. The second nest-type category, the cavity nests, encompasses all those species that either opportunistically adopt suitable cavities or excavate their own burrows into banks or level ground. Most cavity-nesting ovenbirds construct simple woven cups in which to lay the eggs, but some do no more than to provide a layer of plant material on the cavity floor. The final category includes those horneros (*Furnarius*) that build nests from mud.

[*Phleocryptes melanops melanops*,  
Salado's Depression,  
Buenos Aires, Argentina.  
Photos: Yves Bilat]

ing the interior into an entrance way and a nest-chamber, somewhat reminiscent of a snail shell; a cup or platform of grasses or other vegetation holds the eggs. The entrance can be on either the "left" or the "right" side of the nest, but usually faces away from the direction of the prevailing wind.

A second major nest-type category encompasses nests placed in some sort of cavity, treated as a single character by Zyskowski and Prum. For many taxa, the cavity is an abandoned woodpecker hole or a natural hollow, much like those used by "secondary cavity-nesters" worldwide. Ovenbirds with this nest type include species in the genera *Aphrastura*, *Anabazenops*, *Philydor*, *Pseudocolaptes*, *Pygarrhichas* and *Xenops*; *Pygarrhichas* and *Xenops* species also occasionally excavate their own cavity in soft wood. Otherwise, the cavity is frequently in the form of a burrow, typically a horizontal tunnel roughly 1 m long in a vertical or steep dirt bank, such as along an eroded streambed or cliff, often in the upper quartile of the height of the bank. This type of site clearly restricts access to the nest by many kinds of nest predator. The drawback is that the availability of suitable sites of this sort is often highly limited. In many or most cases, it is not certain whether these tunnels are excavated by the ovenbirds themselves or are the abandoned burrows of rodents or other birds. Species known to excavate their own nest-tunnels include at least four species of miner, five *Upucerthia* earthcreepers, the Crag Chilia, nine species of *Cinclodes*, three of *Thripadectes* and four of *Automolus*, one species of *Hylocryptus*, one leaftosser, and the Sharp-tailed Streamcreeper; these numbers will almost certainly grow with further field studies. Some furnariids are known to use burrows excavated by other animals. As examples, the Puna Miner (*Geositta punensis*) uses burrows of rodents known as tuco-tucos (*Ctenomys*) and the Common Miner those of viscachas (*Lagostomus*), whereas the Campo Miner uses tunnels within armadillo (*Dasypodidae*) burrows, the Slender-billed Miner exploits *Upucerthia* burrows, and the Blackish *Cinclodes* uses diving-petrel (*Pelecanoides*) burrows. Many species in these genera, especially *Cinclodes*, also nest in natural crevices in rocks, cliffs, and even buildings.

Within the general category of "cavity", Zyskowski and Prum distinguished several nest types based on the form of the nest itself within the cavity. For example, the White-throated Treerunner lays its eggs simply on the wood chips that accumulate at the bottom of the cavity during excavation. In the few known nests of the tuftedcheeks, the eggs were placed on a thick layer of tree-fern scales (ramenta), which are also sometimes used to cover the eggs when the bird leaves. The Crag Chilia places its eggs on a deep platform of sticks and the stiff feathers of larger birds. At least some species in the genera *Hylocistis*, *Automolus*, *Thripadectes* and *Sclerurus* build a platform that consists exclu-

sively of rachides of compound leaves. The Chaco Earthcreeper and ovenbirds in the genera *Geositta*, *Cinclodes*, *Furnarius* and *Anabazenops* construct a cup of ribbon-like vegetation, such as grass, leaf strips, or strips of inner bark. Cups of lightly woven, wiry plant material, primarily rootlets or fungal rhizomorphs of *Marasmius*, are built by members of the genera *Philydor*, *Automolus*, *Hylocryptus*, *Thripadectes* and *Xenops*. Several species line the nest with downy or pubescent vegetation, that of the genus *Solanum* being mentioned frequently in this context, and spider webs are also commonly recorded as being used in nest lining. Skutch found that the Rufous-breasted and Slaty Spinetails added fresh lining material daily during incubation.

The third major category of nest, a domed structure made of vegetable material, with an entrance on the top, bottom or side that leads to an interior nest-chamber, encompasses the rest of the species in the family for which data are available. Within this general category, nests made of sticks are most common; these are usually thorny if such sticks are available. Likewise, wire, including barbed wire, is often incorporated into the nest in areas where available. These domed stick nests are in general the largest and the most conspicuous of all, and often with little or no attempt being made to conceal them. They are typically added to and repaired whenever necessary during the breeding season; in many cases, the birds seem to adjust the placement of sticks for no apparent reason. Such nests may repel predators in one or more ways. Their placement at ends of branches, or embedded in cactus or other thorny vegetation, may limit predator access, and the thorns and the position of the entrance hole may help to prevent access to the nest-chamber. Those predators too large to use the entrance hole may be discouraged from breaking open the nest by its bulk and tight construction. In fact, some ornithologists have reported on the tremendous labour required, even with tools, to take apart such nests in order to examine their content or interior construction. As a consequence, these nests are also regularly usurped by other bird species, and sometimes by mammals. Reuse of nests by the breeding pair is virtually unknown among the Furnariidae, although reuse within a year has been recorded for the Rufous-fronted Thornbird and the White-whiskered Spinetail. Therefore, because they are so durable, old nests accumulate over time in a species' breeding territory and, as mentioned above, they are used frequently as nests, roosts or refuges by other species of bird, as well as by many other kinds of animal. Ovenbirds with domed stick nests are found in the genera *Eremobius*, *Schoeniophylax*, *Synallaxis*, *Gyalophylax*, *Certhiaxis*, *Thripophaga*, *Asthenes*, *Phacellodomus*, *Anumbius*, *Coryphis-*

Old ovenbird nests are often reused by other species. In order to make an old Rufous Hornero (*Furnarius rufus*) nest suitable for its own purposes, this **Tufted Tit-spinetail** is constructing a simple cup of twigs, grasses, feathers and hair inside the abandoned mud nest. This species will, in fact, use any suitable cavity, such as natural tree holes and woodpecker holes, and also the old stick nests of other furnariids. It breeds in the austral spring and summer, laying 2-4 eggs, which are incubated for 14-15 days.

[*Leptasthenura platensis*, Salado's Depression, Buenos Aires, Argentina. Photo: Yves Bilat]

This **Pallid Spinetail** was caught in the act of stealing twigs from the nest of another species, in this case a Crested Oropendola (*Psarocolius decumanus*). The stealing of nest material in this way has been reported for several furnariids, but this may be the first documented instance for this species. The nest of the Pallid Spinetail is a spherical mass of mostly mosses and lichens, placed among epiphytes on a tree. This ovenbird is restricted to the montane evergreen forest, woodland and mature second growth of south-east Brazil. Although it is not considered to be globally threatened, forest cover within its range has been greatly reduced.

[*Cranioleuca pallida*, Caraça, Minas Gerais, Brazil. Photo: Bret Whitney]

It is probable that this adult **Pale-legged Hornero** has been called off the nest by its partner, which is returning to take over the incubation of the eggs. For most ovenbirds, the sexes are thought to share duties during this stage of the breeding cycle, just as they do during territorial defence, nest-building, and caring for the nestlings and fledglings. Birds that exhibit little or no sexual dichromatism, as is the case with all of the Furnariidae, are usually monogamous and have equal roles. Observations of those ovenbirds that have been studied indicate that one parent incubates for about half an hour at a time, before being relieved by its partner. Incubating constancy varies, with adults being in the nest for 60-90% of the time during the incubation phase.

The Pale-legged Hornero is widely distributed over a large area of northern South America and favours semi-open lowland habitats with bare ground, such as riparian habitats, second-growth woodland edge, farmland and towns.

It is usually found close to water, and in Amazonia, at least, the nest is often placed on a branch hanging over open water. The nest is about 20 cm high, weighs 2 kg and is lined with plant fibres. Unusually, this species has been reported as taking over old mud nests of other *Furnarius* species, and even the stick nests of thornbirds (*Phacelodomus*) and *cachalotes* (*Pseudoseisura*).

The lower photograph, incidentally, provides a very effective illustration of the broad and striking wingbands that are a feature of many members of this family.

[*Furnarius leucopus assimilis*,

The task of brood-rearing is shared by the two parents. Here, the **Thorn-tailed Rayadito** on the right is perched just in front of the nest entrance while its partner, holding food in its bill, is about to enter to feed the young inside the nest. This small, attractive furnariid feeds in trees and undergrowth by gleaning arthropods from foliage, epiphytic growth and the bark of branches and trunks, from the understorey to the canopy. In many respects, it is the ecological equivalent of the tits (*Paridae*) of the Holarctic. Thorn-tailed Rayaditos usually forage in pairs, but during the non-breeding season, in the austral autumn and winter, they often form small foraging flocks of up to, occasionally, 15 individuals.

This species is a common component of the mixed-species feeding flocks within its range, and is considered to be a nuclear species around which other flock-members assemble every day. Curiously for a non-migratory bird, it seems to be capable of long dispersive flights and has successfully occupied several offshore islands, even those which have no tree cover. It has even reached the Falkland Islands. This ovenbird's sole congener is the slightly larger and duller-plumaged Masafuera Rayadito (*Aphrastura masafuerae*), found only on Alejandro Selkirk Island, in the Juan Fernández Islands.

That species is believed to have diverged from the Thorn-tailed Rayadito or to have descended from an ancestor common to both species.

[*Aphrastura spinicauda*

This **Cipo Canastero** is busy providing food for chicks inside its well-camouflaged domed nest.

Closely associated with rocky outcrops, this species forages by gleaning arthropods from rock surfaces and the ground. This photograph is of great interest, because a nest description for this recently described furnariid has yet to be published.

From what can be discerned in the picture, the nest appears to conform to the type commonly built by the genus *Asthenes*, being a mass of interwoven twigs and branches placed low down in shrubby vegetation. The entrance hole is at the top of the nest, and a short tube or tunnel almost certainly leads to the breeding chamber in the heart of the structure.

[*Asthenes luizae*,  
Minas Gerais, Brazil.  
Photo: Anita Studer]

*tera*, *Acrobatornis*, *Pseudoseisura* and, probably, *Metopothrix* and *Xenerpestes*.

Some furnariids with domed stick nests also frequently incorporate into them other conspicuous material, such as feathers, bones, including nearly complete skeletons of reptiles, and cast-off snake skin. Human-made material, such as coloured glass, paper and thread, is also incorporated into the nest by some species. In fact, virtually every sort of trash discarded by humans and accessible to the birds has been recorded as being built into such nests. The Lark-like Brushrunner and the Firewood-gatherer are especially notorious for their use of refuse in this way, and the Rufous-breasted Spinetail is possibly the champion in terms of its use of snake skin. The function of using these materials is, however, unknown.

The dome may also be made of softer plant material. In nests of the *Schizoeaca* thistletails and the Itatiaia Spinetail, the outer layer of material is of *Sphagnum* moss, interwoven with herbaceous plant stems. Species in the genera *Margarornis* and *Premnoplex*, and some *Cranioleuca* spinetails, also use mostly mosses, whereas the material used by Des Murs's Wiretail, the Curve-billed Reedhaunter and some *Synallaxis* and *Asthenes* species is largely grasses or pliable plant stems. In some cases, involving the Straight-billed Reedhaunter and some *Cranioleuca* species, the nest is constructed from a mix of soft plant material and sticks.

The Wren-like Rushbird and the Bay-capped Wren-spinetail, each in a monotypic genus, are unique within the family in the detail of their nests. The former uses mud-coated plant material for the outer wall of the nest, the mud hardening to create a protective shell; the eggs are not laid until the nest dries. The wren-spinetail does not construct a dome over its cup nest, but the surrounding dense grass or reeds function as a wall and dome.

Within the general category of "domed nest", Zyskowski and Prum identified various additional architectural elements. For example, the area of the dome over the nest-chamber is often reinforced with supplementary material, which presumably further shields the eggs and nestlings from rain and sun. This "thatch" is present in the nests of the Chotoy and Red-shouldered Spinetails and those of some *Synallaxis* and *Certhiaxis* spinetails. Three marsh-nesting species, the Wren-like Rushbird and the Straight-

billed and Curve-billed Reedhaunters, also construct an overhead, semicircular shield, or "awning", over the entrance hole. A number of ovenbirds construct protruding, tubular extensions of the nest entrance, some up to 30-40 cm long, usually horizontal and occasionally curving upwards from a lateral entrance to the main section of the dome; these are made of the same material as the main portion of the nest. Such entrance tubes are built by the Band-tailed Earthcreeper, the Red-shouldered Spinetail, and spe-

Similarly, no formal description of the nest of the **Ochre-breasted Foliage-gleaner** exists.

This individual, perched at the nest entrance with a large orthopteran destined for one of its chicks, demonstrates, however, that it is rearing its young inside a natural tree cavity. Extremely little is known of the breeding biology of the Philydor foliage-gleaners. Indeed, nest descriptions have been published for only two of the ten species. From what can be gleaned from these, it appears probable that the members of this genus make a rudimentary cup of grasses and other plant material in a suitable cavity in a tree, bank or wall. There is no evidence that they excavate their own cavities but, with such a paucity of information, it is impossible to be certain.

[*Philydor lichtensteini*,  
Iguazú National Park,  
Misiones, Argentina.  
Photo: Julián Alonso]

Carrying a large spider for its young, this **White-eyed Foliage-gleaner** is about to enter its nest-burrow excavated in an earth bank, a site typical for the genus. This species is an uncommon to common resident in tropical lowland evergreen forest and mature second growth in eastern South America. The subspecies *sulphurascens*, shown here, is widespread in south-central and south-eastern Brazil, eastern Paraguay and north-east Argentina, and occurs in a good number of protected areas. The other two races, however, have very restricted ranges in coastal forest of north-east and east Brazil, areas that have suffered large-scale deforestation. As a result, they are almost certainly at risk of extinction.

[*Automolus leucophthalmus sulphurascens*, Minas Gerais, Brazil. Photo: Anita Studer]

cies in the genera *Synallaxis*, *Certhiaxis*, *Asthenes*, *Phacellodomus* and *Pseudoseisura*. In the nest of the Plain Softtail, two tubes ascend from opposite sides of the single interior nest-chamber; the tubes are draped with vegetation, so that they appear to be part of the interior of the nest.

The interior structure of domed nests also exhibits variation, but it is more difficult to categorize. The passageway from the entrance hole to the nest-chamber can vary in length, from being not much longer than the width of the wall of the nest itself, as with *Schizoeaca* and *Cranioleuca* for example, to being so long that it could be considered an interior tube or tunnel, as with many *Synallaxis*, *Schoeniophylax* and *Pseudoseisura* nests. Those who have studied ovenbird nest construction, such as Narosky and Zyskowski, do not consider these longer tunnels to be homologous to the exterior entrance tubes. The interior tunnels may have special lining materials, including shed reptile skin, as recorded for Rufous-breasted Spinetail nests, and trash; moreover, in the nests of some *Phacellodomus* thornbirds, the tunnel is partially constricted midway along its length, to form an antechamber anterior to the nest-chamber itself. The tunnel may also vary from being straight to being sharply curved. Of course, the orientation of the nest entrance, whether it is on the top, the bottom or the side, dictates to a degree the angle of the tunnel.

Domed nests placed above ground level vary in the way in which they are supported. Possibly the majority are supported from below by a crotch formed by two or more branches, but some are borne by a single horizontal branch. Some nests, such as those of the Marcapata (*Cranioleuca marcapatae*) and Light-crowned Spinetails, the *Premnoplex* barbtails and the *Margarornis* treerunners, are suspended beneath a branch by attachment of the upper surface of the nest, built from the top downwards, to that branch; nests of some of these species may also be suspended from rock overhangs. The *Phacellodomus* thornbirds begin the construction by building the bottom of the nest on a supporting horizontal branch, but the nest becomes so heavy as the bulk increases that its weight causes the branch to bend downwards, thus producing a pensile, or hanging, nest. The Wren-like Rushbird weaves vertical stems of marsh vegetation into the nest wall to provide support, and further cements these to the nest with mud. In the case of other marsh-nesting ovenbirds, such as the Sulphur-throated Spinetail and the Bay-capped Wren-spinetail, the main support for the dome is provided by vegetation below the nest.

Although the variation in nest architecture among the Furnariidae is exceptional, a unifying theme is that all of the

**Straight-billed Reedhaunters** feed their young on a variety of arthropods gleaned from wetland vegetation. The nest is an unusual domed structure made from a mixture of twigs and softer plant material. This ovenbird has very narrow habitat requirements and is found only in stands of spiny *Eryngium* sedge, a fact demonstrated by this nest, which is supported by, and constructed largely from, this plant. These strict ecological requirements, combined with a small geographical range, restricted to extreme south-east Brazil, Uruguay and eastern Argentina, mean that the species has been classified as Near-threatened. Wetlands within its range suffer from pollution, inappropriate waste management, and the drying effects brought about by plantation forestry.

[*Limnornis rectirostris*, Otamendi Reserve, Buenos Aires, Argentina. Photo: José & Adriana Calo]

Brood-feeding is a shared responsibility for this pair of **Grey-headed Spinetails**, as is the case with most ovenbirds. Arthropods are captured by acrobatic gleaning in branches and foliage and by creeping along small branches.

Young furnariids hatch blind, and either naked or covered in down, and are fed in the nest by their parents for 2-4 weeks before fledging.

After fledging, they are still dependent on their parents for food, and the juveniles of many species, such as those of the cachalotes (*Pseudoseisura*), remain in their parents' territory for up to a year or more and may roost with them in the nest. The nest of the Grey-headed Spinetail consists of a large mass of plant material wedged into a fork in a small tree or wrapped around a horizontal branch; access is via a side entrance.

It is typically placed 5-12 m above the ground. This spinetail is restricted to a fairly linear habitat in north-east and south-central Brazil, as it inhabits the narrow ecotone of deciduous forest and semi-deciduous forest found between the humid forest and the dry caatinga woodland.

This linear habitat is restricted by its very nature and is under intense human pressure from coffee-growers, timber extraction and agriculture. Despite these threats, the species appears to survive reasonably well.

[*Cranioleuca semicinerea*, Alagoas, Brazil. Photos: Anita Studer]

This wary **Sooty-fronted Spinetail** is delivering what looks like an adult moth to its hungry chicks. Such visits probably occur once or twice an hour.

The bird is perched on the nest, a large twig structure with an external entrance tube that can, in some cases, be up to 30 cm long. Sooty-fronted Spinetails feed low down in the undergrowth of clearings and along the borders of deciduous forest and riparian woodland in arid areas.

They capture prey by gleaning from low foliage and probably the ground. This species has a large range in eastern South America and is not considered to be at any risk.

[*Synallaxis frontalis*, Minas Gerais, Brazil. Photo: Anita Studer]

nest types provide an unusual degree of physical protection. Whitney and colleagues suggested that domed stick nests arose early in ovenbird evolution, during arid climate phases in south-central South America, in response to the need for protection of nests from wind, sun and cold, and from predators, and because of the absence of other nesting materials. It is tempting to propose that the extraordinary breadth in habitat use by the members of this family is related to this unifying theme of nest protection. Of all passerine nests, those of ovenbirds must rank near the top in the degree of protection that they provide for

delicate eggs and nestlings, sheltering them from the hostile weather extremes faced by many species in terms of heat and cold, aridity and torrential rainfall, constant mist, high winds, and even salt spray. Perhaps this is a key reason why, whether one visits Tierra del Fuego, the Atacama Desert, Cerro Aconcagua in the Andes of west Argentina, or the Chocó region of north-west Colombia, ovenbirds are among the most likely passerines to be encountered.

As might be expected for a family the members of which conceal their eggs within cavities or domed nests, the eggs of

Perched at the nest entrance, and using its tail for support, this **Rufous Hornero** offers a sizeable arthropod to one of its large young. The nest has been constructed with the interior wall aligned differently, putting the entrance at the top, instead of, as with many of the nests of this species, at the side. The breeding biology of this furnariid has been well studied. The Rufous Hornero breeds in the austral spring and summer, with nestlings recorded in all months from October to January; double-brooding is common. The mates share incubation, brooding and chick-feeding duties. Incubation takes 14-18 days and is followed by a nestling phase lasting 3-4 weeks. Juveniles stay in the parents' territory for 4-9 months, but play no part in subsequent nesting attempts.

[*Furnarius rufus rufus*, Salado's Depression, Buenos Aires, Argentina. Photos: Yves Bilat]

During the brood-feeding stage of the breeding cycle, adult **Buff-browed Foliage-gleaners** gather food (Top) while the young chicks wait patiently in the nest (Below). Recorded food items of this species include tent caterpillars, which may well be what the bird in the upper photo has captured. This foliage-gleaner feeds primarily low down in the understorey, but also ranges to the subcanopy and, sometimes, down to ground level. As well as gleaning arthropods from branches, dead leaves and debris and epiphytes, it occasionally hammers on branches. The nest-site shown in the lower photograph, a hollow in a bamboo stem, is typical of a species that will, it seems, adopt any suitable cavity, such as old woodpecker holes or other holes in trees or in walls, and the hollow interior of pipes. Inside the cavity the birds build a shallow cup of twigs. The individual perched at the mouth of this nest is clearly identifiable as a young bird by the obvious pale gape-flanges on the side of the bill base. It is almost fully grown and on the verge of leaving the nest. The Buff-browed Foliage-gleaner has a curious distribution, occurring in two disjunct populations with different habitat requirements. One lives in the montane forests of the Andes from southern Ecuador south to north-west Argentina, and the other is found in the humid lowland forests of south-east Brazil and adjacent areas of Paraguay, Uruguay and Argentina. Of the four subspecies, two occur in each of these two regions. Both of those shown here are individuals from the lowland populations: the adult in the upper picture is of the race *acrita*, with a juvenile of the nominate race in the photo below.

The removal of a faecal sac from the nest by this emerging adult **Pinto's Spinetail** is a good indication of the presence of nestlings, as well as being an essential operation for maintaining nest hygiene. Faecal sacs are either dropped away from the nest or swallowed by the parent bird. The nest of this Critically endangered and poorly known species has not been formally described, but this structure appears to consist of a mass of sticks, perhaps with an external entrance tube, placed low down in dense vegetation. As such, it is typical of those built by many other members of the genus *Synallaxis*.

[*Synallaxis infuscata*,  
Alagoas, Brazil.  
Photo: Anita Studer]

ovenbirds are typically white, those of some species, such as certain *Synallaxis* spinetails, having a bluish tinge and others a greenish or buff tinge. The eggs of the Wren-like Rushbird are deep greenish-blue to turquoise. Patterned eggs have not been recorded. Many ovenbirds are frequent hosts for some avian brood parasites, primarily the American Striped Cuckoo (*Tapera naevia*) and the Shiny Cowbird (*Molothrus bonariensis*). Indeed, *Synallaxis* spinetails and the Yellow-chinned Spinetail are among the primary hosts for the Striped Cuckoo in some areas. The eggs are laid on alternate days, at least in the few species for which data are available.

Clutch size in the Furnariidae exhibits a typical pattern of geographical variation. It is usually two or three in the lowland tropics, whereas species occurring at subtropical or temperate latitudes often lay up to five or more eggs. The Buffy Tuftedcheek possibly lays only a single egg, but this is based on a sample of just one nest. A crucial gap in the knowledge of clutch sizes in the family concerns the many species of the humid Andes, where, although the latitude may be tropical and seasonality minimal, the high elevation makes the climate often quite cold. Do these species have small clutches, as lowland tropical species, or do they lay larger clutches, as those species from more extreme latitudes? This question transcends the Furnariidae, of course, and remains a major lacuna in empirical data that is an obstacle to an understanding of patterns in clutch size. Even for better-known regions, sample sizes for most species are sufficiently small that all statements on clutch size should be regarded with caution.

Data on incubation periods are limited largely to a few examples for under 20 species. The range is from 14 to 22 days, with some tendency for larger species to have longer incubation periods. The 14-day period is for the Tufted Tit-spinetail, whereas the Brown Cachalote, the Buffy Tuftedcheek, the Buff-throated Foliage-gleaner and the Scaly-throated Leaf-tosser are amongst those recorded as incubating for periods of 20 days or more. Skutch found that incubation constancy by the Slaty Spinetail

was 91% during 22 hours of observation at two nests, with the longest period of "egg neglect" being 48 minutes; incubation shifts averaged about 30 minutes for each member of the pair. Data for other species, such as the Rufous Hornero, the Rufous-breasted Spinetail, the Brown Cachalote, the Buff-throated Foliage-gleaner and the Scaly-throated Leaf-tosser, are similar, but with lower incubation constancy, as low as 58% in the case of the foliage-gleaner. At nests of both the Slaty and the Rufous-breasted Spinetails, change-overs are often accompanied by the addition of new downy leaf fragments or spider webs to the nest lining. Eggs of the Rufous Hornero hatch asynchronously, at intervals ranging from 6 to 48 hours. Otherwise, nothing is known of hatching patterns.

The altricial nestlings of ovenbirds are typical of those of the order Passeriformes. The chicks of some species, such as the Rufous Hornero, are naked on hatching, whereas those of others have grey down, this being either sparse, as for instance on hatchlings of the Little and Freckle-breasted Thornbirds, or dense, such as on chicks of the Wren-like Rushbird and the Firewood-gatherer. The eyes of Rufous Hornero and the Scaly-throated Leaf-tosser chicks are fully open in nine days. Nestlings of the Plain Xenops become fully feathered in nine days, but the process takes longer for larger species, such as the Rufous Hornero, the chicks of which are feathered in about 16 days. Nestling Rufous Horneros and Yellow-chinned Spinetails are reported as making hissing noises like snakes and to strike outwards as a means of defending themselves. Older nestlings of most species studied emit loud begging calls. The adults deliver food items to their young at rather slow rates, rarely more than once or twice per hour. They remove the chicks' faecal sacs or swallow them, but hole-nesters, if the example of the Scaly-throated Leaf-tosser is typical, neglect sanitation after the nestlings are old enough to come to the nest entrance for food. Quantitative studies of the growth rates of young ovenbirds are non-existent. The nestlings of several furnariids are attacked by botfly larvae (Gasterophilidae).

From the limited information available, a typical nest-site of the **Campo Miner** is within the burrow of an armadillo (*Dasypodidae*), such as that seen in the left foreground of the upper photo. This furnariid appears to have very specific breeding-habitat requirements, seemingly nesting principally, or perhaps exclusively, on recently burned campo and cerrado grasslands. The grassland surrounding this nest-site had been burned six weeks previously and is about 15 cm tall; it contains few trees or bushes and is broken only by the occasional low termite (*Isoptera*) mound. The adults, which forage on the ground, capture a variety of arthropods, such as mantids, spiders and beetles, and these will be presented to the well-feathered young shown in the lower right-hand picture. The age of these nestlings, here huddled in the nest-chamber 30-50 cm below ground, indicates that the parents must have arrived and set up territory very quickly after the grassland was burned. In fact, some birds appear at burns while the ground is still smoking. This species must be capable of rapid dispersal to suitable breeding areas, sometimes over long distances, but its movements remain something of a mystery. Its conservation status is currently considered to be that of Near-threatened and, bearing in mind that the species has such specific requirements, it is unlikely to be downgraded in the near future. Indeed, the Campo Miner may well become more threatened as its favoured habitat is increasingly converted to mechanized farmland.

The **Uniform Treehunter** is a restricted-range species, occurring only in the Chocó Endemic Bird Area (EBA) of western Colombia and north-west Ecuador. This incredible area of Pacific-slope wet forest is well known for its extraordinarily high biodiversity and, unsurprisingly, contains the largest number of restricted-range species of any EBA in the Americas. Within this region, the Uniform Treehunter is found in mostly montane forest and is considered not to be at risk. Threats to the forested habitats in the region include logging, which has drastically reduced habitat availability, especially in the lowlands, and has encouraged human colonization and associated problems.

[*Thripadectes ignobilis*, 4 km SSW of Chical, Carchi, Ecuador. Photo: Doug Wechsler/VIREO]

The duration of the nestling period is known for some 15 species of furnariid. This ranges from 13 days in the case of the Plain Xenops to at least 29 days in the Buffy Tuftedcheek. Again, larger species tend to have longer nestling periods, those such as the Blackish Cinclodes, the Rufous Hornero and the Brown Cachalote being near the longer end of the range, with small species, such as the Tufted Tit-spinetail and the Rufous-breasted and Slaty Spinetails, near the shorter end.

Although ovenbird nests are such as to discourage many predators, they are not impregnable. Snakes, through their agility, are the main predators. The Guira Cuckoo (*Guira guira*) occasionally enters nests of Rufous Horneros and eats the eggs or young. Similarly, some raptors, such as the Roadside Hawk (*Buteo magnirostris*) and the Black-chested Buzzard-eagle (*Geranoaetus melanoleucus*), occasionally attack them and successfully extract nestlings. Distraction displays, such as the "broken-wing", to lure predators away from nests have not been documented in the Furnariidae.

The length of the post-fledging dependency period is difficult to determine. This is because young of the year often accompany the parents, or remain in their territories, for extended periods, beyond the time when they can forage for themselves. Fledged Slaty Spinetails, for example, feed themselves competently within about 30 days of leaving the nest, but they occasionally accept meals from the parents until at least 45 days. Young Firewood-gatherers remain with their parents for three to four months after fledging, and they sleep with them in the nest at night. The independent young of the Rufous Hornero stay within the parental territory for four to nine months; they may attempt to help with nest-building, but are attacked by the parents when they do so. Likewise, juvenile Brown Cachalotes remain in the territory for five to 13 months, although they do not assist with any subsequent breeding attempts. For many other furnariids, foraging groups of more than two individuals are frequently observed; these almost certainly involve independent young accompanying the parents.

Data on nesting success are scarce. Fraga found that, of 115 Rufous Hornero eggs, 72% produced fledglings, with starvation of the youngest nestling being the primary cause of mortality; this, however, was in heavily disturbed habitat with few nest predators. Nores and Nores found that 59% of 177 eggs

produced fledglings, predation accounting for two-thirds of the mortality. In studies by Skutch, only three of 13 nests of the Slaty Spinetail produced offspring, whereas only two of nine Rufous-fronted Thornbird nests were successful. Before any generalizations can be made about ovenbird nesting success, detailed studies in more natural, undisturbed habitats are required.

Demographic data exist for only one furnariid, the Rufous Hornero. Mason found that the annual adult survival rate of this

**Olog's Cinclodes**, described as recently as 1979, is apparently confined to a small group of mountain ranges in west Córdoba and north-east San Luis, in north-central Argentina. These mountains are classified as an Endemic Bird Area and are home to another restricted-range member of the genus, the Córdoba Cinclodes (*Cinclodes comechingonus*). Both of these furnariids favour the same habitat, that of grassy and rocky areas with patches of *Polyplepis* woodland, and, as many of their genus, they often occur near water. Neither is considered at risk, however, because the area is not threatened by human activity and overgrazing is perhaps the only potential threat.

[*Cinclodes ologi*, La Cumbrecita, Córdoba, Argentina. Photo: Juan Diego Döke]

The enigmatic **Great Xenops** is currently classified as a Near-threatened species.

It has a large range through the interior of eastern Brazil, where it is resident in caatinga, semi-humid woodland and forest.

Although it appears able to tolerate quite high levels of disturbance, it has suffered badly from the rapid and ongoing clearance of forest for agriculture and charcoal production that has taken place in the region.

It is still a poorly known species. Although its bill morphology suggests a connection with *Xenops*, this is the only similarity with that genus. Otherwise, its foraging behaviour indicates a possible link with the *Syndactyla* or *Philydor foliagleaners*, but even they are clearly not close relatives.

[*Megaxenops paraguayae*,  
Lagoa Grande,  
Pernambuco, Brazil.  
Photo: Kevin J. Zimmer]

species in Argentina was about 71%. Otherwise, even anecdotal records of longevity are virtually non-existent.

## Movements

The vast majority of the species in the Furnariidae appear to be permanent residents within their ranges, and perhaps even within individual home ranges. In the absence of data on ringed birds and of year-round studies, however, this is largely an assumption based on a lack of evidence to the contrary.

Long-distance migration is inferred from seasonal distributions for eleven species of the genera *Geositta*, *Upucerthia*, *Cinclodes*, *Phleocryptes*, *Leptasthenura* and *Asthenes*, all of them breeding in southern South America. These appear to be absent from certain areas during the non-breeding season, but present in others only during that season. Long-distance movement is also suspected in one population of the genus *Synallaxis*, the subspecies *australis* of the Pale-breasted Spinetail.

Although the migratory Common, Short-billed (*Geositta antarctica*) and Rufous-banded Miners, and the equally migratory Bar-winged, Cordoba, Grey-flanked and Dark-bellied Cinclodes, have long wings and strong flight capabilities (see Morphological Aspects), other migrants in the family do not. The Scale-throated Earthcreeper, Wren-like Rushbird, Plain-mantled Tit-spinetail and Sharp-billed Canastero have relatively short, rounded wings that would seem to make them unlikely candidates for longer movement.

None of the migratory furnariids is known to migrate more than a few hundred kilometres. Unless the southernmost race *australis* of the Pale-breasted Spinetail is found to move to Amazonia, none of them crosses the equator, unlike some of the austral migrant tyrant-flycatchers, cuckoos and *Sporophila* seedeaters. Moreover, no ovenbird is known to abandon the entire breeding range during the non-breeding season, and in virtually all migratory species some portion of the breeding population is suspected of remaining even at the extreme latitudes of the breeding range.

A number of furnariid species of southern South America are known to make downslope movements after breeding, abandoning the upper elevational portion of their distributions. Many

species of the *puna* zone have also been recorded as temporary downslope refugees during heavy snows. For example, during a particularly severe snowstorm in the Andes of southern Peru, J. O'Neill and Parker counted Bar-winged Cinclodes flying downhill at a rate of about two per minute, and they found substantial numbers of Streak-throated Canasteros and Junin Canasteros (*Asthenes virgata*), hundreds of metres below their normal elevational distribution, among groups of birds that had clearly fled from higher, snow-covered elevations.

It is widely assumed that the migration of ovenbirds is diurnal, and no direct observations of nocturnal movement exist. Further, no studies have been conducted on migration physiology in the Furnariidae. Subcutaneous fat levels in ovenbirds are typically at the low end of any scale, but information on seasonal variation remains to be published. A wealth of data on fat levels resides on the labels of modern museum specimens, but has yet to be analysed.

Some ovenbirds are more widespread in the winter season, presumably a reflection of short-distance dispersal. Flocks of Plain-mantled Tit-spinetails move among oases that may be separated by as much as 50 km of almost barren desert.

One species, the Campo Miner, is essentially nomadic in that it moves from one burned grassland area to another, and apparently requiring recent burns for breeding habitat. The distances involved in these movements are unknown, but they must at times be considerable. This species is known to appear at burns so recent that the ground is still smoking.

Although the Furnariidae have few migratory species, the family does contain some lineages that reveal a capability for crossing substantial barriers to dispersal, including oceans. Two oceanic islands are inhabited by resident furnariids that almost certainly arrived there by means of transoceanic dispersal. The Falkland Islands have an endemic subspecies, the nominate race, of the Blackish Cinclodes; these islands are at least 325 km from the closest point in South America, the continental island of Staten. Even more spectacular is the presence of the endemic Masafuera Rayadito on the island of Alejandro Selkirk, in the Juan Fernández group, about 730 km west of the nearest point on mainland Chile. The same archipelago, which is of volcanic origin and estimated to be 1-6 million years old, also supports the subspecies *baeckstroemii* of the Grey-flanked Cinclodes, which occurs elsewhere only on neighbouring Robinson Crusoe

Another Near-threatened ovenbird is the **Rusty-headed Spinetail**, which is found only in the Santa Marta Mountains of northern Colombia.

Here, it occurs in dense montane tangles and thickets. Despite the designation of the entire area as a national park, serious habitat degradation has taken place, and as little as 15% of the natural vegetation now remains unaffected. Agricultural expansion, logging and burning have all taken their toll, and could ultimately threaten the future of this furnariid and of the 14 other bird species endemic to this mountain range.

[*Synallaxis fusciorufa*,  
Cordillera de Santa Marta,  
Colombia.  
Photo: J. Dunning/VIREO]

The **Red-shouldered Spinetail** is a Near-threatened resident of the dry lowland caatinga formations in north-east Brazil, where it skulks near the ground in the low scrub and undergrowth. Caatinga consists of a variety of semi-desert and dry deciduous forest types, all of which lack grass cover. Human pressure in the region is intense, with agricultural expansion, grazing, hunting and burning all resulting in ongoing habitat removal and degradation. This is reflected in the fact that all five species restricted to this Endemic Bird Area are considered to be at some sort of risk. The situation is not helped by the inadequate protected-area network that covers this bioregion of Brazil.

[*Gyalophylax hellmayri*, Lagoa Grande, Pernambuco, Brazil. Photo: Kevin J. Zimmer]

Island, or Más a Tierra, some 560 km from the Chilean mainland. Although the genus *Cinclodes* has several species that are excellent fliers and are regularly noted as wanderers, the only other *Aphrastura* species, the Thorn-tailed Rayadito, has short wings and is not suspected of making any movements greater than local wandering.

A further indication of the general sedentary nature of most species of ovenbird is the scarcity of records of extralimital wanderers. The Bar-winged *Cinclodes* alone is responsible for almost all such records.

### Relationship with Man

With their dull plumage, unremarkable voices and often secretive or, at least, inconspicuous behaviour, it is no surprise that ovenbirds do not in general figure prominently in local cultures or legends. Representing yet another range in extremes in the Furnariidae, however, the Rufous Hornero is possibly the bird species more familiar to more South American people than is any other. With its large and unusual nests often placed directly on human-made structures such as fence posts and telephone poles, and on attention-catching spots such as cow skulls and large cans, and with its abundance in human-modified and human-created habitats, including cities and towns, the Rufous Hornero makes itself well known to human neighbours. Frequently mentioned in Argentine poetry and literature, it is the national bird of Argentina, as well as the namesake of that country's leading ornithological journal, *El Hornero*, one of the oldest and most prestigious ornithological publications in Latin America. The loud, explosive duetting behaviour of mated Rufous Horneros further highlights this ovenbird's presence and "personality". Thus, colloquial names for the species are numerous, as are local legends about it and its nests. According to H. Sick, in Brazil, the occasional sealed nest has led to the legend that males will seal up and entomb unfaithful females in the nest. Members of the Caxiuanã tribe credit the Rufous Hornero with teaching their ancestors how to make clay pots.

Although lacking the charisma of the Rufous Hornero, the Bar-winged *Cinclodes* competes for the honour of being one of the small birds most familiar to South American people. Virtually ubiquitous in the higher and drier portions of the Andes, a region with one of the highest human population densities on the continent, both historically and currently, the Bar-winged *Cinclodes* is perhaps the most likely passerine to be seen in much of the non-forested Andes. Its affinity for foraging along tiny ditches and in puddles, irrigation channels and muddy spots, as well as its usually confiding nature, makes it a well-known species to all people of agricultural areas of the puna zone and the Altiplano region.

Perhaps no ovenbird is so familiar to a local human population as is the Blackish *Cinclodes* to the inhabitants of the Falkland Islands. As described by O. S. Pettingill, this furnariid shows the classic insular syndrome of a lack of fear of humans coupled

Because of its small geographical range and the threats to its habitat, the **White-throated Barbtail** is listed as Vulnerable by BirdLife International. It is found in two small mountain ranges in northern Venezuela, where it forages among epiphytes in the understorey of humid montane forest. In the past, conversion to agriculture and pastureland has reduced the area of forest, and this is continuing, even within the two national parks that encompass much of the species' current range. All six furnariid species largely confined to these mountains are at risk, and the protection offered by the national parks in the region must be improved to ensure their survival.

[*Premnoplex tatei*, Paria Peninsula National Park, Venezuela. Photo: Martin Vestergaard]

Although fairly widespread, the **Campo Miner** is currently considered Near-threatened owing to threats to its cerrado habitat, a tall-grass savanna formation, in south-central Brazil and north-east Bolivia. It appears to be a semi-nomadic specialist, seeking out recently burned open grassland, and has no doubt been adversely affected by the cessation of burning in some areas. Other threats are more typical and include the conversion of cerrado to agriculture, pasture and forestry, activities that have detrimentally affected over two-thirds of this miner's habitat.

[*Geositta poeciloptera*,  
Serra da Canastra  
National Park,  
Minas Gerais, Brazil.

with dramatic flexibility and adaptability in foraging behaviour. Blackish Cinclodes will follow beachcombers to glean food exposed by the disturbance. They will readily take food offered by hand, and will enter open windows to steal food from tables.

No ovenbird has been a victim of direct human exploitation. Again, this is not surprising, given the absence in the family both of large or colonial-nesting species that would be potentially exploitable for meat or eggs, and of melodious or beautiful species that may be desirable as cagebirds. This fact, along with the largely arthropod diet of these birds, also explains why no furnariid species has been domesticated or has become prominent in aviculture.

Ovenbirds pose no threat to any agricultural grains or fruits. In fact, because of their diet, they would appear to be beneficial to farmers. Thus, the vast majority of furnariids do not harm humans or their interests in any way. Perhaps the only exception is the problem created by the heavy nests of the Rufous Hornero and the Firewood-gatherer when they are placed on electrical equipment and support poles. According to Sick, one study in southern Brazil revealed that, of 580 nests of Rufous Horners placed on utility poles and equipment, more than 45% were positioned in a way that created a risk of short-circuiting the system. In the same area, the nests of Firewood-gatherers cause even more damage to electrical systems, particularly because this species frequently incorporates wire and other metal into the nest (see Breeding). The only other example of damage caused by ovenbirds is the anecdotal reports of the occasional eating of chicken eggs by the Brown Cachalote.

### Status and Conservation

Of the 236 species of furnariid, 26, equivalent to 11%, are considered by BirdLife International to be globally threatened. The conservation status of three of these is regarded as Critical, with nine Endangered and 14 Vulnerable. In addition, the subspecies *huancavelicae* of the Creamy-breasted Canastero, treated by some as a separate species, is classified as Vulnerable.

Of the 26 threatened ovenbirds, four live in humid forest remnants of eastern Brazil. They include two of the three Critical species, Pinto's Spinetail and the Alagoas Foliage-gleaner, the other two being the Bahia Spinetail (*Synallaxis cinerea*) and

the Pink-legged Graveteiro. A further three, the Blackish-headed Spinetail (*Synallaxis tithys*), the Rufous-necked Foliage-gleaner and the Henna-hooded Foliage-gleaner, inhabit deciduous forest of south-west Ecuador and north-west Peru. Similarly, arid scrub in the Marañón Valley of Peru is home to the Marañón Spinetail (*Synallaxis maranonica*), the Great Spinetail and the Chestnut-backed Thornbird, all classified as Vulnerable. Humid forest in south-eastern Brazil and *Polylepis* woodland in the Andes each hold two globally threatened species. The Striated Softtail and the Canebrake Groundcreeper occur in the

As the **Masafuera Rayadito** is restricted to one small island in the Juan Fernández group, off the coast of Chile, where its population was estimated at fewer than 150 individuals in 2002, it is not surprising that its conservation status is that of Vulnerable. It occurs in dense tree-fern forest along watercourses. Since all forested habitats have already been cleared from lowland parts of the island, the Masafuera Rayadito is restricted to the hill forest.

As is typical on oceanic islands, introduced species pose the main threat, and trampling by goats could be opening up the forest and causing habitat fragmentation. Fencing, or even the culling of the goats, may have to be considered.

former, and the Royal Cinclodes, classed as Critical, and the White-browed Tit-spinetail are inhabitants of the latter.

The remaining twelve threatened species are somewhat scattered geographically and ecologically. Of these, the Hoary-throated and Russet-bellied Spinetails, the Bolivian Spinetail, the Russet-mantled Softtail and the Cipo Canastero are listed as Endangered. The conservation status of the White-bellied Cinclodes, the Masafuera Rayadito, the Perija Thistletail, the Apurimac Spinetail, the Orinoco Softtail, the White-throated Barbtail and the Bolivian Recurvebill is Vulnerable.

A further 17 furnariids are considered Near-threatened. In addition, the subspecies *dissita* of the Rusty-backed Spinetail, confined to Coiba Island, in Panama, and sometimes treated as a full species, is currently regarded as Near-threatened.

The global population of the Royal Cinclodes is extremely small, possibly no more than a few hundred individuals. Indeed, it was believed to total fewer than 250 birds in the year 2000. This ovenbird has been recorded at only six localities in the Andes. Although two of these are in officially protected areas in Bolivia, at Puina, in the Madidi National Park, and in the Ilampu Valley, in the Cotapata National Park, even there they are at risk. *Polylepis* woodland throughout the Andes has been severely fragmented by the effects of human exploitation, and there is mounting evidence that the total area of this special habitat has been reduced dramatically during the last few thousand years. Losses have been particularly severe in the latter decades of the twentieth century. The remaining patches of *Polylepis* in Cuzco and Apurimac, in Peru, are not officially protected and are still being burned to improve pastures; widespread cutting for firewood is also leading to further degradation. Moreover, uncontrolled fires and grazing prevent the regeneration of woodlands. The Royal Cinclodes was almost certainly much more widely distributed at one time. Whether it can survive for much longer is dependent on the ability of humans to treat with due seriousness the importance of protecting its habitat and maintaining effective conservation measures.

The two other furnariids considered to be at the greatest risk of extinction are both confined to Alagoas, in north-east Brazil. One of these, the Alagoas Foliage-gleaner, not described until 1983, has so far been observed at just a single site, Murici. When first found, it was said to be relatively easy to locate in the existing lowland evergreen forest, which covered an area of

8500 ha. Later surveys, however, failed to confirm that this species was in any way common; indeed, the foliage-gleaner was not seen at all between 1992 and 1997. A single individual was recorded in each of the following two years, and four were found in 2000. By then, the forest in which this ovenbird lives had been greatly reduced, and is currently thought to survive only as a remnant patch of about 1500 ha. Even this small fragment, despite legal protection, is subject to cutting and uncontrolled fires. The total population of the Alagoas Foliage-gleaner is estimated at fewer than 250 individuals, and is declining rapidly as a result of habitat destruction. Unfortunately, the forest at Murici is privately owned, and several conservation initiatives aimed at preventing further loss of habitat have proved unsuccessful. If this species is not to become extinct, it is considered essential that protection measures at Murici be enforced and that the forest be afforded reserve status.

Although certainly more numerous than the previous species, Pinto's Spinetail is nevertheless placed in the same category with regard to its conservation status. Its range in Alagoas is tiny, not much bigger than that of the Alagoas Foliage-gleaner, and it, too, is declining in numbers owing to the rapid deforestation in the region. Although it appears to be locally fairly common, it has been recorded in recent years at only a couple of localities. One of these is Murici, where the problems are those outlined in the preceding paragraph. Fortunately, Pinto's Spinetail is also present in the Pedra Talhada State Park, where a programme of replanting is helping to restore the forest; this reserve is protected by law and patrolled by guards, whose efforts at enforcing the law are evidently supported by the local people and appear to be largely successful. On the other hand, it is of concern that this species has apparently not been observed in recent decades at any other sites. It was recorded in 1980 in the Salinho Biological Reserve, in the adjoining state of Pernambuco, and there are earlier records from the UFPE Ecological Station and other localities in both Alagoas and Pernambuco. The current population of Pinto's Spinetail is believed to be in the range of 1000-2500 individuals, but is thought to be declining.

As so many ovenbirds exhibit a narrow habitat specialization (see Habitat), many species that do not appear on "official" lists of species of concern nevertheless have vulnerably small populations. The linear nature of their habitat ensures that the

**The White-bellied Cinclodes** is currently found in just two areas of extreme high-altitude boggy terrain in the puna of central Peru, where it is rare and local. Its distribution suggests that it has very specific ecological requirements, and it appears to live only in mineral-rich, wet Distichia bogs with nearby rocky outcrops and stony slopes, conditions sometimes found below glaciers in the region where it occurs. The tiny size of both its range and its known population gives cause for concern, but actual threats are few. Nevertheless, planned mining operations, if carried out, would almost certainly adversely affect the future of this Vulnerable species.

[*Cinclodes palliatus*, Curicocha, Junín, Peru. Photo: Alejandro Tello]

The **Hoary-throated Spinetail** is another threatened furnariid with strict habitat demands. It is restricted to gallery forest along the headwaters of the Rio Branco, in northern Brazil and extreme western Guyana. Until recent years this rare species remained unobserved, and it is still poorly known. It has been recorded from just a few sites, where it appears to frequent the dense understorey of seasonally flooded gallery forest within 500 m of the river. Its tiny range and the linear nature of its habitat combine to produce a population estimate of fewer than 1000 individuals. The major threat to this Endangered species may be uncontrolled burning and the development of rice cultivation.

[*Synallaxis kollari*,  
Rio Uraricoera,  
Roraima, Brazil.

Photo: Arthur Grosset]

total area of that habitat and, consequently, the bird populations that it supports are much smaller than would be suspected from inspection of range maps or statements on distribution. Conservation biology in general does not adequately address the problem of linear habitats. For example, the many species of ovenbird restricted to the successional stages of major Amazonian rivers must have tiny populations by comparison with those of other habitats, because the band of suitable habitat at any one river margin may be so narrow that it is capable of supporting only

one territory. If the true width of the range of such species were faithfully indicated on maps, it would be too small to be visible. Furthermore, for the riverine and, especially, the river-island specialists, suitable habitat is seldom, if ever, continuously distributed in the "long axis" dimension of the geographical range, thereby compounding the tendency to overestimate the area of suitable habitat.

This problem of linear habitats and their inherently small bird populations is masked by our natural tendency to illustrate ranges

First discovered as recently as 1985, the **Cipo Canastero** is restricted to a small area of campos in the Serra do Cipó region of south-east Brazil. It occurs around rocky outcrops and associated shrubby vegetation within grassland, is known from just half a dozen sites, and is considered to be Endangered. Threats include fire, often used as a management tool to clear new pastureland, and the potential impact of brood parasitism by the Shiny Cowbird (*Molothrus bonariensis*), a new colonist. Recent fieldwork, however, indicates that this canastero may be more widespread than was thought. Further surveys should help to clarify the species' range and allow an accurate assessment of its status.

[*Asthenes luizae*,  
Serra do Cipó,  
Minas Gerais, Brazil.  
Photo: Edson Endrigo]

Substrate specialization and the fact that the species is known from only seven sites in an area of coastal Brazil that has suffered near-total deforestation combine to make the future prospects of the **Striated Softtail** rather uncertain. This furnariid is considered to be Endangered. It is confined to the Atlantic Forest Lowlands EBA, where it is seldom found far from the dense subcanopy vine tangles that occur in its favoured primary and infrequently disturbed secondary forests. Habitat destruction is still rife, and constitutes the biggest threat to the species. Ensuring the continued protection of the two reserves in which the softtail is known to occur may be important for its future survival.

by "filling in" areas on maps with continuous shading. Besides riparian zones, another example that affects ovenbirds is the linear nature of the timber-line ecotone on the humid slope of the Andes. The matrix of grass, shrubs and stunted trees at the interface between cloudforest and treeless high-elevation habitats naturally exists over a narrow elevational zone. The ovenbirds that seem largely restricted to this ecotone include all of the *Schizoeaca* thistletails, the Line-fronted, Many-striped, Junin and Scribble-tailed Canasteros, and possibly the Tawny Tit-spinetail, and the Itatiaia Spinetail is confined to a similar ecotone in south-east Brazil. Although the ranges of such furnariids may span hun-

dreds of kilometres of latitude, the band of suitable habitat is so narrow that the total populations of species restricted to this ecotone are surely also small. As recently shown by M. Kessler and S. Herzog, this ecotone has been narrowed even further by human activity, particularly burning and grazing.

On a broader scale, all species restricted to natural, relatively undisturbed habitats is, of course, declining as these habitats are converted to human use, and all are, in effect, endangered over the longer term. Whether the few reserves established in South America can support viable populations of these species is unknown. At one end of this scale are the species found in those

One of the most threatened of all ovenbirds is **Pinto's Spinetail**, a Critically endangered species at real risk of extinction in the short term. It is restricted to an area of less than 80 km<sup>2</sup> in the coastal forest of Alagoas and Pernambuco, in north-east Brazil, a region that has only 2% of natural forest cover remaining and where one bird species has already become extinct in the wild. The spinetail is currently known from perhaps three sites, only one of which is under beneficial conservation management. Elsewhere, initiatives have so far failed to deliver habitat improvement for this species and forest loss continues.

[*Synallaxis infuscata*,  
Alagoas, Brazil.  
Photo: Anita Studer]

Over time, the use of fire for land management, coupled with heavy grazing, has prevented the regeneration of the Polylepis woodland and montane scrub that is the habitat of the **Royal Cinclodes**. This species' distribution in the Andes of south-east Peru and west Bolivia is now very fragmented. Fewer than 250 individuals survive, and these are threatened by continued habitat loss.

It is little wonder that this species is Critically endangered. Its future is likely to depend on action taken at community level, aimed at segregating agricultural, grazing and forest areas, replanting of Polylepis woodland, and the planting of buffer woodlands as alternative sources of firewood.

[*Cinclodes aricomae*,  
Abra Málaga, Peru.

forested areas where the percentage of remaining habitat is small, namely the Atlantic Forest region of eastern and south-eastern South America, the deciduous forest of the Tumbesian region of north-west Peru and south-west Ecuador, and the cloudforests of the northern Andes.

In every case of threatened or declining populations of furnariids, anthropogenic habitat destruction or degradation is the principal cause or primary threat. Deforestation, conversion of wildlands to agriculture, or degradation through grazing or fragmentation are, as expected, the primary agents of habitat destruction. For a family of generally small birds suffering no direct commercial exploitation, and with only two oceanic islands having members, it seems likely that the figure of 11% of all furnariid species considered threatened is unusually high. This almost certainly reflects the narrow habitat and foraging restrictions that characterize many species in the family, which in turn leads to small geographical ranges, and to the high percentage of species that are sedentary, thereby facilitating differentiation and speciation.

Even those ovenbirds with relatively large ranges or broad habitat preferences may suffer disproportionately dramatic population losses due to forest fragmentation or selective logging. In French Guiana, J. M. Thiollay has found that leaf-tossers, xenops, and *Philydor* and *Automolus* foliage-gleaners were among the species of small insectivores of interior forest that disappeared or declined dramatically after selective logging of tropical forests. A similar pattern of dramatic declines or total disappearance of common ovenbirds of interior forests from fragments has also been found by P. Stouffer, R. O. Bierregaard and colleagues near Manaus.

The degree to which habitat restriction and destruction can influence a species' ultimate survival is well illustrated by the situation of the Pink-legged Graveteiro. As outlined by Pacheco, Whitney and L. P. Gonzaga, this newly discovered bird is found only in the thinned canopy above cocoa plantations, which can be only a modified version of this bird's pristine habitat, now completely gone. Furthermore, this remnant population is probably at the precarious upper elevational limit of its former range, because all forest lower down has been removed. Thus, the graveteiro's survival relies completely on an anthropogenic habitat to which the bird has adapted to some extent, but the persistence of this habitat depends, for the present, on patterns of human land use, local profitability of cocoa plantations, and the global

market for cocoa. For example, a fungus that began to reduce cocoa production in the early 1990s has already caused plantation-owners to shift to other products and has led to the removal of some plantations in the region.

By contrast, ovenbirds are found in some of the most inhospitable habitats in South America, where human impact is minimal and is likely to remain that way. As a result, many furnariids in the genera *Geositta*, *Upucerthia*, *Cinclodes* and *Asthenes* are among the continent's bird species that are the least affected by anthropogenic activities. Others tolerate at least moderate overgrazing and light cultivation, and so persist or thrive in the highly disturbed inter-Andean valleys and Altiplano, where human civilizations have modified the landscape for thousands of years.

Those species in the Furnariidae that are increasing are, as expected, the ones that thrive in human-modified landscapes. Although quantitative data are lacking, the non-forest ovenbirds that flourish in human-created second growth and scrub, such as many *Synallaxis* spinetails and *Furnarius* hornbills, have almost certainly expanded their populations and ranges greatly within the last two centuries.

PLATE 11

inches 3  
cm 8

# Genus *GEOSITTA* Swainson, 1837

## 1. Campo Miner

### *Geositta poecilopectera*

**French:** Géositte des campos **German:** Camposerdhacker **Spanish:** Minero Brasileño

**Taxonomy.** *Anthus poecilopecterus* Wied, 1830, "Inner Campos Geraës of Brazil" = Minas Gerais-Bahia border.

Often placed in a monotypic genus *Geobates* on account of slightly smaller size, shorter tail and bill, and bright cinnamon axillaries, but otherwise similar to current congeners in behaviour and voice. Plumage features and lowland distribution suggest related to *G. cunicularia*. Monotypic.

**Distribution.** Interior Brazil (locally from C Mato Grosso, S Goiás and C Bahia S to C Minas Gerais, São Paulo and N Paraná) and E Bolivia (extreme NE Santa Cruz).

**Descriptive notes.** 11-12 cm; 17-19 g. Small, short-tailed miner with bright rufous wing pattern and medium-length bill. Has crown dull greyish-brown with darker brown vague spots on centres of feathers, these becoming more elongated towards nape; supercilium buff, rest of face dull rufescent brown with vague darker flammulations; back dull greyish-brown, rump and uppertail-coverts tinged rufescent; lesser and median wing-coverts dark brownish with indistinct paler margins, indistinct wingbars, and blackish and rufous pattern on remiges (broad chestnut-rufous wingband); short tail slightly notched, rectrices nearly rounded, ru-

fous, blackish-brown subterminal band; throat whitish, contrasting with brown-freckled dull buff upper breast; lower breast and belly buff to whitish, flanks and undertail-coverts pale rufous; axillaries bright cinnamon; iris brown; upper and distal part of lower mandible dark horn or blackish, base of lower mandible pale horn or pinkish-grey; tarsus and toes pale brown to pale grey or dull pinkish. Differs from other members of genus in smaller size, shorter tail and bill, generally darker coloration, cinnamon axillaries. Sexes alike. Juvenile undescribed. **Voice.** Male song a repeated whistled "sweep" in display-flight; call "pit-pit".

**Habitat.** Campo grassland and treeless cerrado, especially where recently burned; 500-1250 m. Perhaps a specialist on recent burns, at least when breeding.

**Food and Feeding.** Arthropods; recorded items brought to nestlings are Hymenoptera, Coleoptera, mantids (Mantidae), spiders. Forages singly or in pairs. Food gleaned from ground.

**Breeding.** Nests found in Sept. Wing-raising display from termite mound and hovering aerial display recorded. Three nests known in detail, each evidently in side tunnel within armadillo (*Prionodontes maximus*, *Cabassous unicinctus*) burrow, nest-chamber lined with dead grass and hair; one contained 3 eggs. No further information.

**Movements.** Probably resident; as it appears so soon at burns, even when ground still smoking, must be highly vagile and capable of long-distance movements, but data lacking.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally uncommon to rare. Rare in Serra da Canastra National Park, in Brazil, and in Noel Kempff Mercado National Park, in Bolivia; in Brazil, occurs also in Das Emas National Park and Pedra Talhada State Park. Agriculturalization of campo and cerrado regions of Brazil pose substantial long-term threat to this species; its apparent restriction to these habitats, and especially to burnt areas, is considered by some to place it at risk, to the point that its conservation status may merit reappraisal.

**Bibliography.** Bates *et al.* (1992), Buzzetti (2003a), Cory & Hellmayr (1925), Ihering (1914), Killeen & Schulenberg (1998), Naumburg (1930), Parrini *et al.* (1999), Pinto (1978), Remsen (2003a), Ridgely & Tudor (1994), Sick (1993), Silveira (1998), Stotz *et al.* (1996), Willis (1992b).

## 2. Common Miner

### *Geositta cunicularia*

**French:** Géositte mineuse **German:** Patagonienerdacker **Spanish:** Minero Común

**Taxonomy.** *Alauda cunicularia* Vieillot, 1816, environs of Río de la Plata and in pampas of Buenos Aires, Argentina.

Plumage characters suggest closest relationship is with *G. poecilopectera*, *G. tenuirostris* and *G. antarctica*. Has been considered to form superspecies with *G. peruviana*, but this is unlikely. Vocal differences suggest that Andean races may constitute a separate species from lowland nominate race; *deserticolor* (with *georgei*) may represent another. Race *fissirostris* possibly indistinguishable from nominate. Racial identity of population in W Argentina (Salta S possibly to Mendoza) uncertain, presumed to be *hellmayri*. Distribution of races in need of careful review. Nine subspecies tentatively recognized.

#### Subspecies and Distribution.

*G. c. juninensis* Taczanowski, 1884 - Andes of C Peru (Junín, Huancavelica).  
*G. c. titicacae* J. T. Zimmer, 1935 - Andes of S Peru (Ayacucho to Puno), Bolivia (La Paz and Cochabamba to Potosí), N Chile (Tarapacá) and NW Argentina (Jujuy to Mendoza).  
*G. c. frobeni* (R. A. Philippi [Krumwiede] & Landbeck, 1864) - Pacific slope of Andes of S Peru (Arequipa to Tacna).  
*G. c. georgei* Koepeke, 1965 - coastal S Peru (S Ica, W Arequipa).  
*G. c. deserticolor* Hellmayr, 1924 - coastal S Peru (Arequipa) S to N Chile (N Atacama).  
*G. c. fissirostris* (Kittlitz, 1835) - C Chile from coast to Andes (S Atacama S to Llanquihué).  
*G. c. contrerasi* Nores & Yzurieta, 1980 - WC Argentina (Sierras Grandes, in Córdoba).  
*G. c. hellmayri* J. L. Peters, 1925 - Andes of C Chile (Malleco) and SW Argentina (C Neuquén to NW Chubut); presumably also this race in W Argentina (Salta and Tucumán S perhaps to Mendoza).  
*G. c. cunicularia* (Vieillot, 1816) - lowlands from E Argentina (S from S Córdoba and S Corrientes), extreme SE Brazil (SE Santa Catarina, Rio Grande do Sul), Uruguay and S Chile (S from Aisén) S to Tierra del Fuego.

**Descriptive notes.** 14-17 cm; 20-34 g. Medium-sized miner with medium-length bill, and conspicuous wing pattern. Nominata race has broad whitish supercilium, rest of face rather messy, pale brownish, vague darker postocular line and moustachial streak; crown and upperparts dull greyish-brown with indistinct pale edging, crown feathers with darker brown central spots, spots becoming more elongate towards nape; uppertail-coverts with pale brownish tips; wings mostly dull brownish, wing-coverts with dull pale buff tips, primaries with broad pale rufous area (broad wingband); tail slightly notched,

rectrices buff-whitish basally, blackish distally, with pale rufescent transition between pale and dark areas, extent of pale area increases laterally, outer web of outer rectrix nearly all white; throat whitish, breast buff-white with brownish wavy streaks, belly pale buffy whitish, flanks faintly tinged pale cinnamon, undertail-coverts whitish; iris brown to yellowish-brown; bill black to brown, sometimes pale base of lower mandible; tarsus and toes dark grey to black. Sexes alike. Juvenile undescribed. Races vary considerably in size and weight, also in paleness of plumage: *titicacae* is large, paler and more buffy than nominate, with paler, almost creamy tail base, less distinct breast streaking; *juninensis* is like previous but even paler and more buffy, almost without breast markings; *frobeni* has buffy white uppertail-coverts, almost whitish base of tail, whiter underparts than previous; *deserticolor* is like last, but smaller and paler overall, especially back, wingband, face and underparts, and uppertail-coverts are grey like back; *georgei* resembles previous, but darker wings and tail, pale yellowish-buff (not whitish) underparts, heavier breast spotting; *fissirostris* is very like nominate but slightly grayer above, whiter below, darker chest markings, more sharply defined terminal band on inner remiges; *hellmayri* resembles previous, but uppertail-coverts whiter, base of tail paler, chest markings paler; *contrerasi* is significantly smaller on average than last (but measurements overlap), wings and tail blackish, darker than other races, creamy buff below, well-defined dark brownish or blackish breast spots. **Voice.** Song a loud, shrill series of notes given in flight, "de-dirr-rr-rrr", nominate race more as "ta whit-ta whit". Flight call a high-pitched "keep" or rich, sweet "pip", nominate a nasal "deedijer" or "er?"; also trilled notes.

**Habitat.** Puna grassland, temperate grassland, and arid lowland scrub; sea-level to 5000 m. Found in a variety of open habitats, flat or gently sloping, with short grass, often with scattered shrubs and rocks, and often where soils disturbed, as along dirt roads; locally, sandy soils along coast, including *restinga* scrub. Distribution evidently patchy in many areas; perhaps restricted to places having sandy soil suitable for nest-tunnel construction.

**Food and Feeding.** Arthropods and some seeds; recorded items are Diptera and Coleoptera, including larvae. Forages solitarily or in pairs. Food gleaned from ground.

**Breeding.** Breeds generally during austral spring-summer; eggs in Sept-Dec in Chile and Argentina; nestlings in Oct-Nov in Argentina; fledglings in Oct-Dec in S Chile and Argentina. Oct in Brazil, Oct-Nov in Peru, Dec in N Bolivia; 2 broods per year, possibly only in some areas. Presumably monogamous. Nest at end of horizontal tunnel 0.4-3.5 m long excavated in bank or (usually sloping) ground, floor of nest-chamber with padding 8-10 cm across of grasses, hairs, flowers, feathers and rootlets, sometimes only barely padded. Clutch 2-3 eggs; incubation and care of young by both sexes.

**Movements.** Andean races evidently largely resident, with some downslope movement after breeding (*titicacae*, *contrerasi*, *hellmayri*); some post-breeding movement N in C Chile and SW Argentina (*hellmayri*). Individuals in extreme S (nominate) migrate N, but S limit of non-breeding range uncertain.

**Status and Conservation.** Not globally threatened. Common to locally abundant in variety of habitats with light to moderate anthropogenic disturbance, and found over a large geographical and elevational range. Occurs in Aparados da Serra National Park, in Brazil. Possibly at risk in SE Brazil, where extensive development of beach areas on Santa Catarina I could lead to local extinction.

**Bibliography.** Anon. (2003d), Araya & Chester (1993), Belton (1984), Bond (1945), Canevari *et al.* (1991), Chesser (1994), Contreras (1975, 1979c), Contreras & Hoy (1980), Cory & Hellmayr (1925), Cuello (1985), Esteban (1951b), Fjeldsa & Krabbe (1990), Fraga & Narosky (1985), Grigera *et al.* (1996), Hoy (1980), Hudson (1920), Johnson (1967), Koepeke (1954, 1963, 1965, 1970), Krabbe *et al.* (1996), Lönnberg (1903), Morrison (1939), Naka *et al.* (2002), Narosky (1975a), Narosky *et al.* (1983), Navas & Bö (1987), Nores & Yzurieta (1980), Nores *et al.* (1983), Parker *et al.* (1982), de la Peña (1987, 1988), Peters (1925), Philippi *et al.* (1954), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Salvador (1988, 1990), Selater & Hudson (1888), Serié & Smyth (1923), Sick (1993), Stotz *et al.* (1996), Vaz-Ferreira (1973), Vuilleumier (1991, 1993a), Walker (2001), Wetmore (1926), Willis (1992b), Zimmer (1935b, 1936a), Zotta (1936).

## 3. Slender-billed Miner

### *Geositta tenuirostris*

**French:** Géositte à bec grêle **German:** Dünnschnabel-Erdhacker **Spanish:** Minero Picudo

**Taxonomy.** *Alauda tenuirostris* Lafresnaye, 1836, no locality = Sicasica, La Paz, Bolivia. Plumage characteristics suggest most closely related to *G. cunicularia*; separation of the two in conventional linear sequences is a result of overemphasis on bill morphology in traditional taxonomy. Some specimens from NW Peru (Cajamarca) intermediate between nominate race and *kalimayae*. Two subspecies recognized.

#### Subspecies and Distribution.

*G. t. kalimayae* Krabbe, 1992 - Andes of C Ecuador (Cotopaxi).  
*G. t. tenuirostris* (Lafresnaye, 1836) - Andes of Peru (Cajamarca S to Arequipa in W, and S from Huánuco on E slope), Bolivia and NW Argentina (S to Tucumán; one record La Rioja).

**Descriptive notes.** 16-18 cm; 32-38 g. Large miner with long, decurved bill. Has dull buffy whitish supercilium, vague dark brownish postocular band and poorly defined moustachial streak; rest of face messy pale buffy brownish; crown dull brown, with dark brown feather centres forming vague wavy streaks; upperparts dull greyish-brown, some feathers indistinctly edged paler, rump and uppertail-coverts slightly paler than back; wing-coverts dark brown, with broad dark buff tips and edges forming indistinct wingbars; flight-feathers dark fuscous with rufescent

*kalimayae* is smaller, greyer, with darker wings and tail, breast more streaked. **VOICE.** Song given in flight, sometimes continued on ground, a repetitive series of “jit” or “keek” notes, c. 4 per second, can last for 20 seconds or more. Call(s) described as sharp “keeeek”, “week, week”, “chwea” or nasal “kyeenh”.

**Habitat.** Puna grassland and scrub, sloping or flat, also pastures and agricultural land; often near water; 2500–4600 m.

**Food and Feeding.** Recorded dietary items are Coleoptera, Lepidoptera larvae, spiders, and springtails (Collembola). Solitary or in pairs. Gleans and probes on ground; also excavates invertebrates from ground.

**Breeding.** Season generally during austral summer, but little information available; eggs in Dec, in Argentina. Presumably monogamous. Male performs song-flight in display. Nest in tunnel possibly made by *Upucerthia* earthcreepers in bank; tunnel c. 60 cm long leads to nest-chamber c. 14–15 cm in diameter; nest is a pad c. 2 cm deep of dried grasses lined with cattle hair. Clutch 2 eggs. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common, including in lightly farmed areas. No obvious threats.

**Bibliography.** Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fjeldsá & Krabbe (1990), Fjeldsá & Mäijer (1996), Fraga & Narosky (1985), Johnson (1967), Koepcke (1954, 1970), Krabbe (1992a), Mazar Barnett & Pearman (2001), Morrison (1939), Narosky *et al.* (1983), Norez & Yzurieta (1981), Olrog (1956, 1963a), Parker *et al.* (1982), Pearman (1994f), de la Peña (1988), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Sallaberry *et al.* (1992), Salvador *et al.* (1984), Stotz *et al.* (1996), Taczanowski (1884), Walker (2001), Zimmer (1930).

## 4. Short-billed Miner

### *Geositta antarctica*

**French:** Géositte à bec court    **German:** Feuerland-Erdhacker    **Spanish:** Minero Austral

**Taxonomy.** *Geositta antarctica* Landbeck, 1880, Tierra del Fuego.

Plumage and morphological features suggest most closely related to *G. cunicularia*. Monotypic.

**Distribution.** S Argentina (S Santa Cruz S to N Tierra del Fuego) and S Chile; W & S Argentina in non-breeding season.

**Descriptive notes.** 15–16 cm; 34–40 g. Moderate-sized miner with relatively short bill, and no prominent wing markings. Has pale supercilium, dark line behind eye; dull greyish-brown above, whitish uppertail-coverts; long, dark brown wings, narrow ill-defined greyish wingband; tail blackish-brown, except outer three rectrices mostly whitish; dull whitish below, breast streaked light buff-brown; iris brown; bill blackish, paler base of lower mandible; tarsus and toes blackish. Sexes alike. Juvenile has pale-tipped crown feathers, less conspicuous breast markings. **VOICE.** A series of doubled notes, “weetuk-weetuk-weetuk-weetuk”; flight call a shrill “tjeeek, de trrit, trrittrrittrrittrrit”.

**Habitat.** Southern temperate grassland; barren plains with sparse grassland, scattered shrubs; also in sandy coastal areas. Sea-level to 1000 m.

**Food and Feeding.** Arthropods and seeds, gleaned from ground. Forages solitarily or in pairs.

**Breeding.** Breeds in austral summer; nests with eggs in Nov and young in Jan in S Chile. Presumably monogamous. Nest at end of tunnel 0.5–1.5 m long excavated in side of dune, floor of nest-chamber padded with a few grasses. Clutch 3 eggs.

**Movements.** Mainly resident, e.g. present on Tierra del Fuego all year round. In Argentina, some post-breeding movement northwards and downslope; recorded N to Mendoza.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Southern Patagonia EBA. Abundant to fairly common. Habitat occupied appears to be reasonably safe from anthropogenic disturbances, with the exception of overgrazing.

**Bibliography.** Anon (2003e), Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Chesser (1994), Contreras & Hoy (1980), Cory & Hellmayr (1925), Couve & Vidal-Ojeda (1999), Esteban (1951b), Fjeldsá & Krabbe (1990), Humphrey *et al.* (1970), Johnson (1967), Mazar Barnett & Pearman (2001), Olrog (1963a), de la Peña (1988), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1980a, 1991).

## 5. Greyish Miner

### *Geositta maritima*

**French:** Géositte grise    **German:** Südlicher Grauerdhacker    **Spanish:** Minero Gris  
**Other common names:** Shore Miner

**Taxonomy.** *Certhilauda maritima* d’Orbigny and Lafresnaye, 1837, Cobjia, “Bolivia” (= northern Chile).

Possibly closest to *G. peruviana*, as suggested by some plumage similarities, small size and biogeography, but absence both of wingband and of rufous in tail unique within genus. Monotypic.

margins, rufous inner remiges; tail slightly notched, central rectrices dull brown, darker towards tip, paler and more rufescent at base, rest of feathers rufous with dark brown subterminal areas decreasing in extent laterally, outer two pairs virtually all rufous, outer web of outer rectrix pale cinnamon; throat whitish, breast buff-white with indistinct brownish wavy streaking, belly pale buffy whitish, undertail-coverts pale tawny; iris brown; bill blackish, pinkish base of lower mandible; tarsus and toes black. Sexes alike. Juvenile is more rufous throughout, has pale edges on back and crown feathers. Race

**Distribution.** W Peru (S from Ancash) and N Chile (S to Atacama).

**Descriptive notes.** 12–13 cm; 16–17 g. Small, dull miner with medium-length bill, without wingband or highly patterned tail. Has dull buff supercilium, vague blackish-brown postocular line, rest of face messy brownish; crown dull brownish-grey, upperparts slightly paler; wings dull greyish-brown, indistinct paler margins on wing-coverts; tail slightly notched, central rectrices dull greyish-brown, rest blackish, outer web of outer rectrix whitish; underparts dull greyish-white, slightly darker on breast, flanks tinged dull salmon-pink; iris dark brown; bill blackish, proximal half of lower mandible pale grey to pinkish-horn; tarsus and

toes black. Sexes alike. Juvenile is more buffy throughout, tips of wing-coverts paler and more buffy. **VOICE.** Song an unmusical “te-cerrrr” sometimes followed by additional series of rising and falling notes; call described as “siet”, “plyt-plyt” or “plyt”.

**Habitat.** Arid lowland scrub; flat to hilly or mountainous, rocky and sandy desert, usually with little or no vegetation; sea-level to 2600 m, sometimes to 3500 m.

**Food and Feeding.** Arthropods and some seeds, gleaned or excavated from ground. Forages singly or in pairs.

**Breeding.** Season presumably during austral summer; eggs in Nov in Chile. Presumably monogamous. Nest at end of tunnel, possibly excavated by the birds themselves, in ground. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common within its restricted habitat. Unsuitability of most of its habitat for use by humans appears to insulate this species from most threats.

**Bibliography.** Araya & Chester (1993), Cory & Hellmayr (1925), Fjeldsá & Krabbe (1990), Johnson (1967), Koepcke (1963, 1970), Mazar Barnett & Pearman (2001), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stotz *et al.* (1996), Taczanowski (1884).

## 6. Coastal Miner

### *Geositta peruviana*

**French:** Géositte du Pérou    **German:** Nördlicher Grauerdhacker    **Spanish:** Minero Peruano  
**Other common names:** Little Miner

**Taxonomy.** *Geositta peruviana* Lafresnaye, 1847, vicinity of Lima, Peru.

Some plumage similarities, small size and biogeography have suggested to some authors that it is most closely related to *G. maritima*, although fundamental differences in wing and tail patterns may indicate otherwise. Has been considered to form a superspecies with *G. cunicularia*, but this thought unlikely. Three subspecies recognized.

**Subspecies and Distribution.**

*G. p. paytae* Menegaux & Hellmayr, 1906 - NW Peru (Piura, Lambayeque, La Libertad, Ancash).

*G. p. peruviana* Lafresnaye, 1847 - W Peru (Lima).

*G. p. rostrata* Stolzmann, 1926 - SW Peru (Ica).

**Descriptive notes.** 12–13 cm; 16–19 g. Small, pale miner with medium-length bill, conspicuous wing pattern in flight. Has buffy whitish supercilium, rest of face pale sandy greyish-brown; crown and upperparts sandy greyish-brown, rump and uppertail-coverts slightly paler; wings mostly sandy greyish-brown, paler margins on wing-coverts, broad pale tawny wingband on remiges; tail slightly notched, central rectrices pale rufescent with conspicuous, broad dark brownish shaft streaks, rest of feathers mostly blackish, some pale dull rufescent at base increasing in extent towards outer feathers, outer web of outer rectrix whitish; underparts whitish, slightly darker on breast; iris dark brown; bill blue-grey or grey-horn, palest at base of lower mandible; tarsus and toes creamy whitish to greenish-grey. Sexes alike. Juvenile undescribed. Race *paytae* is considerably paler than nominate; *rostrata* resembles previous, but even paler, less brownish, above, with larger, blacker bill. **VOICE.** Song by male in display-flight a prolonged musical twittering; call a short “tuit” or “tswit”.

**Habitat.** Arid lowland scrub; sparsely vegetated, usually sandy, coastal desert; also on *lomas*; from near sea-level to 700 m.

**Food and Feeding.** Arthropods, gleaned from ground. Forages solitarily or in pairs.

**Breeding.** Eggs in Jun. Presumably monogamous. One nest was at end of 2-m tunnel sloping downwards in sandy, level ground, other possible nests in tunnel in dirt bank; not known whether tunnel excavated by birds themselves. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Peru-Chile Pacific Slope EBA. Fairly common within the habitat which it occupies. Unsuitability of most of its habitat for use by humans insulates this species from most threats.

**Bibliography.** Bond (1945), Cook (1996), Cory & Hellmayr (1925), González *et al.* (1998), Koepcke (1954, 1963, 1965, 1970), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Vaurie (1972, 1975), Vuilleumier (1980a, 1982), Williams (1981).

## 7. Dark-winged Miner

### *Geositta saxicolina*

**French:** Géositte à ailes sombres    **German:** Zimthals-Erdhacker    **Spanish:** Minero Alioscuro  
**Other common names:** Black-winged Miner

**Taxonomy.** *Geositta saxicolina* Taczanowski, 1875, Junin, Peru.

Plumage similarities suggest that it is most closely related to *G. punensis* and *G. rufipennis*. Monotypic.

**Distribution.** Andes of C Peru (Pasco, Junín, Lima, Huancavelica).

**Descriptive notes.** 15-16 cm; 31-35 g. Large miner with medium-length bill, no conspicuous wing pattern. Has indistinct cinnamon-buff supercilium and side of neck, slightly darker auriculars and loreal area; crown dull brownish with darker brown feather centres, forehead tinged dull rufescent; back and rump dull brownish with cinnamon tinge, uppertail-coverts pale tawny whitish; wing-coverts mostly dull brown with some paler edging, remiges dull brown with darker fuscous primary tips; tail square to slightly notched, pale tawny at base, blackish-brown distally, tips dull rufous, amount of blackish decreases progressively from central to outer feathers, as does paleness of tawny area, outer web of outer rectrix whitish; throat whitish, breast buff, belly buff-white; iris brown; bill black, paler base of lower mandible; tarsus and toes black. Sexes alike. Juvenile is more buffy throughout, has dark scaling on breast. VOICE. Song not described; flight call “titi-titi”, “tir-tir-tir” or “cheerp, cheerp”.

**Habitat.** Puna grassland; on sparsely vegetated grassy or rocky slopes in puna; mostly at 3700-4900 m.

**Food and Feeding.** Arthropods and occasionally seeds, gleaned from ground. Forages solitarily or in pairs.

**Breeding.** Virtually no data available. Breeding presumably during austral summer; fledglings in Dec. Nest is in tunnel at base of large rocks.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Junín Puna EBA. Fairly common within its limited range. Most of the habitat occupied by this species is unsuitable for use by humans, rendering it relatively safe from most threats.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Koepcke (1954, 1970), Morrison (1939), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884).

## 8. Puna Miner

### *Geositta punensis*

**French:** Géosite du puna

**German:** Altiplano-Erdhacker

**Spanish:** Minero Puneño

**Taxonomy.** *Geositta punensis* Dabbene, 1917, La Quiaca, 3300 metres, Jujuy, Argentina. Plumage similarities suggest that closest relationship is with *G. saxicolina* and *G. rufipennis*. Monotypic.

**Distribution.** Altiplano region of Andes of extreme S Peru (Puno), W Bolivia (La Paz S to Potosí), NW Chile (Tarapacá S to Atacama) and NW Argentina (Jujuy S to Catamarca).

**Descriptive notes.** 13.5-14.5 cm; 22-29 g. Medium-sized miner with medium-length bill, conspicuous wing pattern. Has supercilium buffy whitish, rest of face mostly pale greyish-brown; crown to rump relatively uniform pale sandy brown, uppertail-coverts much paler; wing-coverts and remiges dark brownish, broadly margined buff-whitish, pale tawny-rufous base of remiges forming conspicuous wingband; tail square to slightly notched, rectrices pale tawny-rufous at base, this colour increasing in extent laterally, dark brownish (central pair) to blackish distally, all tipped pale tawny-rufous, outer web of

outer rectrix white; underparts pale buff-white, faintly tinged tawny on flanks; population in NW Argentina may be slightly paler in coloration; iris brown; bill blackish, base of lower mandible blue-grey; tarsus and toes dark grey. Sexes alike. Juvenile undescribed. VOICE. Song a long shrill series of “veeo” notes, rising early and then descending, with some interspersed faster, chattier notes, may last more than 20 seconds; often given in flight display. Flight call a sharp, rich “pzea” or “kvee”.

**Habitat.** Puna grassland; mainly flat Altiplano grassland and barren puna, often sandy; occasionally on bare slopes of brushy ravines. Mainly 3200-4600 m; locally down to 3050 and up to 5000 m.

**Food and Feeding.** Arthropods and seeds, gleaned from ground. Feeds singly or in pairs.

**Breeding.** Breeds during austral summer; eggs and young in Oct-Jan in Chile; fledglings in Jan in Bolivia and Argentina. Presumably monogamous. Nest usually at end of burrow made by tuco-tucos (*Ctenomys*) in dry, sandy soil. Clutch 2-3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common. Coexists with humans on heavily grazed Altiplano, and presumably has done so for thousands of years. No known threats.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parker *et al.* (1982), de la Peña (1988), Remsen (2003a), Remsen & Traylor (1989), Ribero (1991), Ridgely & Tudor (1994), Rocha & Quiroga (1996), Stotz *et al.* (1996).

## 9. Rufous-banded Miner

### *Geositta rufipennis*

**French:** Géosite à ailes rouges

**German:** Rotschwanz-Erdhacker

**Spanish:** Minero Rojizo

**Other common names:** Red-winged Miner

**Taxonomy.** *Geobamon rufipennis* Burmeister, 1860, Paraná, Entre Ríos; error = Sierra de Tucumán, Argentina.

Plumage similarities suggest that closest relationship is with *G. saxicolina* and *G. punensis*. Birds from C Chile sometimes separated as race *hellmayri*, but considered probably better placed within race *fasciata* (in any case, former name preoccupied by *G. cunicularia hellmayri*). Sight records

from S Bolivia (Tarija) also included with latter, but racial identity requires confirmation. Seven subspecies tentatively recognized.

**Subspecies and Distribution.**

*G. r. fasciata* (R. A. Philippi [Krumwiede] & Landbeck, 1864) - W Bolivia (La Paz S to Potosí; sight records from Tarija) and Pacific slope of N & C Chile (Atacama S to Malleco).

*G. r. harrisoni* Marin *et al.*, 1989 - N Chile (SW Antofagasta).

*G. r. rufipennis* (Burmeister, 1860) - NW Argentina (Jujuy S to San Juan).

*G. r. fragai* Nores & Yzurieta, 1986 - NW Argentina (Cerro Famatina, in La Rioja).

*G. r. ottowi* Hoy, 1968 - WC Argentina (Sierra de Córdoba).

*G. r. hoyi* Contreras, 1980 - W Argentina (Mendoza S to N Neuquén) and S Chile (S Aisén).

*G. r. gilaui* Contreras, 1976 - SW Argentina (S Neuquén S to Chubut).

**Descriptive notes.** 14-17 cm; 25-54 g. Middle-sized to large miner with straight, medium-length bill, striking wing pattern. Nominative race has conspicuous pale supercilium, dark grey-brown postocular line, rest of face messy brownish-grey; crown to uppertail-coverts uniform dull sandy olive; wing dull grey-brown with paler edgings, rufescent area at base of remiges forming conspicuous broad rufous wingband; tail square to slightly notched, central rectrices dull tawny at base, blending to greyish-brown centrally, with conspicuous broad blackish subterminal area and dull tawny tip, outer rectrices with brighter,

more rufescent base and progressively more reduced dark subterminal area; throat whitish, breast pale brownish-buff, belly paler, tinged cinnamon, often some cinnamon on flanks; undertail-coverts dull pale tawny; iris brown; bill blackish-grey, most of base of lower mandible paler horn; tarsus and toes blue-grey. Sexes alike. Juvenile undescribed. Races differ substantially in size, also in colour tones: *ottowi* (described from only 2 specimens) is larger and greyer than nominate, with narrower wingbars, paler underside of wings; *fragai* is greyer above, with darker wings and tail, breast greyer, less ochraceous; *hoyi* is almost pure grey dorsally, mostly pinkish-grey below, breast tinged greyer; *gilaui* resembles previous, but slightly darker and greyer above, wingband evidently less extensive, is also significantly longer-billed; *fasciata* is greyer above, and darker overall; *harrisoni* is smaller still (by 10% in linear measurements, 30% in body mass), with whiter belly than previous, little or no rufous on flanks and undertail-coverts. VOICE. Song a fast series (c. 5 per second) of buzzy, trilled notes on same pitch, interrupted by bursts of faster notes, may last more than 20 seconds, decelerating somewhat at end; given in display-flight or from prominent perch on rock.

**Habitat.** Puna grassland and arid montane scrub; dry rocky slopes, plateaux, or flat areas with scattered vegetation, also banks of dry riverbeds. Mainly 3100-4400 m in Andes, down to 2200 m in mountains of C Argentina; to near sea-level locally in Chile (Atacama).

**Food and Feeding.** Arthropods; also seeds, especially of *Coliguaya odorifera* (Euphorbiaceae), and leaf buds. Forages solitarily or in pairs; in loose single-species flocks on migration. Food items gleaned from ground.

**Breeding.** Breeds during austral summer; eggs in Nov-Mar in Argentina; nestlings in Nov in Chile. Presumably monogamous. Nest at end of tunnel 0.4-1.2 m long excavated 0.5-0.7 m from top of wall of bank or ravine, sometimes in crevice in rocks, floor of nest-chamber with bits of grass, hairs and feathers or, at times, deeper platform up to 1 cm thick and 15-17 cm in diameter. Clutch 2-3 eggs.

**Movements.** Mainly resident; some post-breeding movement to lower elevations in Chile and Argentina. S races migratory, move N after breeding, but non-breeding range uncertain; migrants occur in flocks of up to 500.

**Status and Conservation.** Not globally threatened. Fairly common throughout range. Habitat reasonably safe from anthropogenic disturbance, except overgrazing.

**Bibliography.** Chebez *et al.* (1999), Contreras (1976, 1980f), Cory & Hellmayr (1925), Dabbene (1917), Esteban (1949, 1951b), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Grigera *et al.* (1996), Hoy (1968a), Johnson (1967), Krabbe *et al.* (1996), Marin *et al.* (1989), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Nellar (1993), Nores (1986), Nores *et al.* (1983), de la Peña (1987, 1988), Remsen (2003a), Remsen & Traylor (1989), Ribero (1991), Ridgely & Tudor (1994), Salvador (1990), Stotz *et al.* (1996), Taczanowski (1884), Volkmann & Cargnelutti (2001), Vuilleumier (1993a), Wetmore (1926).

## 10. Creamy-rumped Miner

### *Geositta isabellina*

**French:** Géosite isabelle

**German:** Hellbürzel-Erdhacker

**Spanish:** Minero Grande

**Other common names:** Isabelline Miner

**Taxonomy.** *Certhilauda isabellina* R. A. Philippi [Krumwiede] and Landbeck, 1864, Cordilleras of Santiago Province, Valle Largo and Los Piqueños, at 7000 and 10,000 feet [c. 2100 and 3000 m], Chile.

Plumage similarities suggest that closest relationship is with *G. saxicolina*, *G. punensis* and *G. rufipennis*. Monotypic.

**Distribution.** Andes of C Chile (Atacama S to Talca) and extreme WC Argentina (Jujuy, Catamarca, San Juan, Mendoza).

**Descriptive notes.** 17.5-18.5 cm; 38-48 g. Large miner with relatively long decurved bill, no conspicuous wing patch. Has pale supercilium; uniform pale sandy buff above, contrasting creamy-white rump and uppertail-coverts; tail buff, central rectrices and broad subterminal band blackish; throat whitish, breast and belly light ochraceous cream to greyish-cream; iris brown; bill blackish, base of lower mandible yellowish-horn; tarsus and toes blue-grey. Sexes alike. Juvenile has pale spots on crown. VOICE. Song loud, strident trill of 3-12 notes, given in display-flight or from prominent perch on rock.

**Habitat.** Puna grassland; in puna on barren slopes of high Andes, especially near rocky outcrops, at 3000-5000 m; often lower in non-breeding season.

**Food and Feeding.** Arthropods, gleaned from ground and rocks. Feeds singly or in pairs.

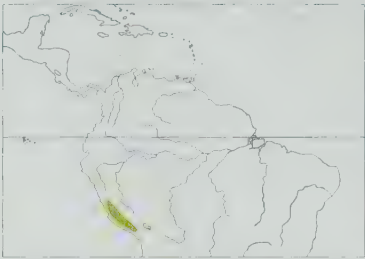

**Breeding.** Season presumably during austral summer; young in Feb in Chile. Presumably monogamous. Nest at end of tunnel excavated in sloping ground. Clutch 3 eggs.  
**Movements.** Mainly resident; some downslope movement, to 2000 m, after breeding.  
**Status and Conservation.** Not globally threatened. Uncommon, and with small geographical range. Habitat is reasonably safe from anthropogenic disturbances, except overgrazing.  
**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Johnson (1967), Mazar Barnett & Pearman (2001), Navas & Bo (1987), Olrog (1963a), Peña (1961), de la Peña (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996).

11. Thick-billed Miner

*Geositta crassirostris*

**French:** Géositte à bec épais    **German:** Dick Schnabel-Erdhacker    **Spanish:** Minero Picogrueso

**Taxonomy.** *Geositta crassirostris* P. L. Selater, 1866, Lima, Peru.  
Relationships to other members of genus uncertain, but present species differs vocally. Two subspecies recognized.  
**Subspecies and Distribution.**  
*G. c. crassirostris* P. L. Selater, 1866 - coastal hills of W Peru (Lima).  
*G. c. fortis* Berlepsch & Stolzmann, 1901 - Andes of SW Peru (Lima S to Arequipa).  
**Descriptive notes.** 16-18 cm; 49-54 g. Large miner with large, thick, long bill, conspicuous rufous and black patch in wing. Has whitish supercilium, dark grey-brown crown with darker brown feather centres; upperparts dark dull brownish-grey, feathers variably margined paler, rump slightly paler, uppertail-coverts tinged browner; wing-coverts dull brownish-grey with paler margins, remiges dark fuscous-brown with paler edgings and rufous bases, latter forming broad wingband, black terminally; tail square to slightly notched, central rectrices dull greyish-brown, faintly tinged

rufescent, darker along shaft, paler at tip, other rectrices dull rufous at base with blackish subterminal area diminishing in extent towards outer feathers, dull rufous-buff tips; underparts greyish-white, slightly darker on breast; iris brown; bill blackish, base of lower mandible blue-grey; tarsus and toes whitish to pale grey. Sexes alike. Juvenile undescribed. Race *fortis* differs from nominate in being paler, more rufescent above, mottling not so dark, rufous wingband broader, terminal black wingband narrower. **VOICE.** Song a series of c. 10 wheezy notes, rising and then falling in pitch, lasting c. 5 seconds. Flight call “chirp”; other calls

are loud, plaintive notes, also loud “quien, quien” or “keen, keen”.  
**Habitat.** Arid montane scrub; brushy ravines adjacent to arid, rocky slopes with scattered shrubs and cacti, at 600-3550 m.  
**Food and Feeding.** Arthropods and some seeds, gleaned and excavated from ground. Solitary or in pairs.  
**Breeding.** No information.  
**Movements.** Resident.  
**Status and Conservation.** Not globally threatened. Restricted-range species: present in Peru-Chile Pacific Slope EBA. Uncommon. Habitat occupied appears reasonably safe from anthropogenic disturbances, except overgrazing.  
**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Koepcke (1954, 1963, 1970), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Schulenberg (1987a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1930).

## Genus *UPUCERTHIA*

### I. Geoffroy Saint-Hilaire, 1832

## 12. Scale-throated Earthcreeper

### *Upucerthia dumetaria*

**French:** Upucerthie des buissons

**German:** Schuppenkehl-Erdhacker

**Spanish:** Bandurrita Común

**Other common names:** Scaly-throated Earthcreeper

**Taxonomy.** *Upucerthia Dumetaria* I. Geoffroy Saint-Hilaire, 1832, Patagonia = banks of the Río Negro, Argentina.

Some similarities in plumage suggest that it is most closely related to the group formed by *U. albigula*, *U. jelskii* and *U. validirostris*. Proposed race *hallinani* (N Chile, NW Argentina) appears to represent clinal extreme of paleness at N end of range of *hypoleuca*. Patterns of geographical variation conform in general with Gloger's Rule, with populations from arid areas usually the palest in coloration. Four subspecies recognized.

#### Subspecies and Distribution.

*U. d. peruana* J. T. Zimmer, 1954 - Andes of S Peru (Puno).

*U. d. hypoleuca* Reichenbach, 1853 - W Bolivia, C Chile (Antofagasta S to Maule) and W Argentina (Jujuy S to N Río Negro, E to Córdoba).

*U. d. saturator* Scott, 1900 - C Chile (S possibly from Malleco, to Valdivia) and SW Argentina (W Neuquén S to W Chubut).

*U. d. dumetaria* I. Geoffroy Saint-Hilaire, 1832 - S Chile (Aisén, Magallanes) and C & S Argentina (Córdoba and Buenos Aires S to N Tierra del Fuego).

**Descriptive notes.** 20-22 cm; 37-55 g. Large earthcreeper with long, strongly decurved bill. Nominant race has whitish supercilium, rest of face grizzled greyish-white and dark dull greyish-brown; crown dull, dark greyish-brown with faint mottling, especially on forehead; back to uppertail-coverts uniform dull brownish-grey; wings greyish-brown with paler edgings, base of remiges dull rufous; tail rounded, central rectrices dull greyish-brown, slightly browner than back, other rectrices blackish-brown with dull rufous tips, rufous increasing in extent outwards; chin whitish, throat whitish with thin dark bars, breast dark

greyish-brown with pale scalloping, belly whitish, blending to greyish-brown on flanks, dull grey-brown undertail-coverts; iris dark brown; bill blackish; tarsus and toes dark brown. Sexes alike. Juvenile is finely streaked on forehead and back, more extensively marked below. Race *hypoleuca* is like nominate, but more rufous above, with rufescent tinge in wings, more buffy below; *saturator* is much darker above and below than other races, upperparts with olivaceous tinge, central rectrices dusky brown without rufous tinge, lacks pale tips to wing-coverts, greyer and less buffy below, breast markings more prominent, bill reportedly slightly shorter and less strongly decurved; *peruana* (known from 2 specimens) resembles previous but slightly less dark, bill longer, rufous in wing less sharply outlined. **Voice.** Song "chippy, chippy, chippy, chip"; calls a wheezy "keet" and sharp, dry "dzit".

**Habitat.** Arid montane scrub, arid lowland scrub, and *puna* grassland, to 4000 m. Inhabits shrubby slopes and shrub-steppe (e.g. *Atriplex*), with ravines or rocky outcrops, and rocky grassland.

**Food and Feeding.** Arthropods. Usually solitary. Forages by probing and gleaning ground.

**Breeding.** Breeds during austral summer; eggs and nestlings in Oct-Dec in Chile and Argentina. Presumably monogamous. Nest at end of tunnel 1-2 m long excavated in bank or sloping ground, entrance sometimes hidden by vegetation and branches, occasionally in hole in structure or in crevice among rocks; floor of nest-chamber with a pad of loose grasses. Clutch 2-4 eggs.

**Movements.** Mainly resident, with some post-breeding downslope movement. Nominant race probably leaves Tierra del Fuego and other parts of extreme S after breeding, migrates northwards to as far as N Argentina (to Tucumán, Santiago del Estero and Entre Ríos) and S Uruguay; in Chile, *saturator* occurs N to Aconcagua in non-breeding season.

**Status and Conservation.** Not globally threatened. Fairly common in S portion of range. Evidently very rare in N; in Bolivia has been found at just a few localities, and no recent records; in S Peru, race *peruana* known only from two specimens collected more than 50 years ago. Habitat is reasonably safe from anthropogenic disturbances, overgrazing being the only potential threat.

**Bibliography.** Anon. (2003d), Araya & Chester (1993), Blendinger (2003), Bond (1945), Canevari *et al.* (1991), Contreras (1975, 1978), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Johnson (1967), Lönnberg (1903), Marin *et al.* (1989), Narosky & Di Giacomo (1993), Narosky *et al.* (1983), Navas (1971), Nores *et al.* (1983), Olog (1963a), Parker *et al.* (1982), de la Peña (1987, 1988), Peters (1923), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Salvador (1988), Selater & Hudson (1888), Stotz *et al.* (1996), Vuilleumier (1993a), Wetmore (1926), Zimmer (1954), Zotta (1938).

## 13. White-throated Earthcreeper

### *Upucerthia albigula*

**French:** Upucerthie à gorge blanche

**Spanish:** Bandurrita de Arica

**German:** Weißkehl-Erdhacker

**Taxonomy.** *Upucerthia albigula* Hellmayr, 1932, Putre, 11,600 feet [c. 3530 m], Tarapacá, Chile. Plumage similarities suggest that it is most closely related to *U. jelskii* and *U. validirostris*. Monotypic.

**Distribution.** W slope of Andes in SW Peru (S from Ayacucho) and N Chile (Tarapacá).

**Descriptive notes.** 18-19 cm; 36-42 g. Large earthcreeper with long, relatively thick-based, strongly decurved bill. Has broad buffy whitish supercilium extending forward to lores, rest of face dark brownish with paler flammulations; rich dark brown above, darkest on crown; wings dark rufescent brown, all but outermost two primaries with bright rufous outer webs, more rufous at base of remiges (broad wingband); tail rounded, dark rufescent brown, slightly paler towards outer feather pairs and at tips; throat whitish with some faint darker feather tips laterally, breast dull buffy brown with vague streaking (paler areas along

shafts), more speckled at sides, blending into paler belly; flanks darker, faintly tinged rufescent, undertail-coverts dull pale rufous with paler tips; iris brown; bill blackish, sometimes paler base of lower mandible; tarsus and toes black to dark brown or grey. Sexes alike. Juvenile has darker crown, more conspicuous markings on throat and breast. **Voice.** Song a series of 4-10 slightly descending dry, harsh, scolding "chit" notes; call a high-pitched "chit".

**Habitat.** Arid montane scrub; sparsely vegetated slopes, brushy ravines, desert scrub, and adjacent hedgerows of pastures and agricultural land; mostly 3050-3700 m, locally down to 2300 m and up to 3900 m.

**Food and Feeding.** Arthropods. Usually solitary. Probes and gleans ground.

**Breeding.** Season probably during austral summer; eggs in Nov in Chile. Presumably monogamous. Nest at end of tunnel excavated in bank. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Peru-Chile Pacific Slope EBA. Uncommon to locally fairly common. Has small geographical range. Habitat is reasonably secure at present, with overgrazing the only potential threat.

**Bibliography.** Araya & Chester (1993), Fjeldså & Krabbe (1990), Hellmayr (1932), Johnson (1967), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Schulenberg (1987b), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 14. Plain-breasted Earthcreeper

### *Upucerthia jelskii*

**French:** Upucerthie de Jelski

**German:** Fahlkehl-Erdhacker

**Spanish:** Bandurrita de Jelski

**Taxonomy.** *Coprotretis Jelskii* Cabanis, 1874, Junin, Peru.

Closest to *U. albigula* and *U. validirostris*. Has been considered to form a superspecies with latter, and may be conspecific; considered together, the two exhibit a stepped cline in plumage coloration (increasingly rufescent to S) and perhaps a smooth cline in measurements, and songs sound very similar (although written descriptions differ somewhat); on the other hand, they appear to overlap in range in S Bolivia (Potosi); further study needed. Vocally distinctive race *pallida* possibly a separate species. Three subspecies recognized.

#### Subspecies and Distribution.

*U. j. saturata* Carriker, 1933 - W Andes of C Peru (Ancash, Huánuco, NW Pasco).

*U. j. jelskii* (Cabanis, 1874) - Andes of C Peru (Lima, Junin, Huancavelica).

*U. j. pallida* Taczanowski, 1883 - Andes of S Peru (Ayacucho, Arequipa, Cuzco, Apurímac, Puno), N Chile (Tarapacá), W Bolivia (La Paz S to Potosi) and NW Argentina (Jujuy).

**Descriptive notes.** 17-19 cm; 33-42 g. Medium-sized to rather large, rather plain earthcreeper with strongly curved, relatively thin bill. Has pale buffish-white supercilium, nearly uniform dull brown crown and upperparts, some paler flecking on forehead; wings like back, nearly uniform, hint of rufous at base of remiges (inconspicuous rufous-brown wingband); tail rounded to nearly square, dark brown, becoming progressively more rufescent towards outer feathers; throat greyish-white with faint dull brownish feather tips, upper breast similar but feather margins more conspicuous, producing scaled appearance, lower

breast to undertail-coverts plain light greyish-buff, lower flanks darker; iris brown; bill black, base of lower mandible sometimes paler; tarsus and toes blackish to dark brown. Sexes alike. Juvenile has more rufous in wings and tail, approaching *U. validirostris* in this respect but with dusky edges of secondaries. **Voice.** Song a rich irregular trill "drrrrr..." rising and then falling in pitch, accelerating and then decelerating, repeated at short intervals; song of *pallida* lower-pitched and slower "tuirrrrr", with a few introductory notes, and less change in pitch. Call a metallic "click" or "tyi-ik".

**Habitat.** Arid montane scrub; rocky, shrubby slopes, especially in washes and ravines, and rocky *puna* grassland; mostly 3200-4600 m, locally down to 3000 m and up to 5000 m.

**Food and Feeding.** Arthropods; recorded items are lepidopteran larvae, and larvae and adults of Coleoptera. Forages solitarily or in pairs. Probes in and gleans from ground.

**Breeding.** Breeds during austral summer, in Jan-Feb in C Peru; nestlings in Feb in S Peru, and eggs in Nov in Chile. Presumably monogamous. Nest at end of tunnel 1-1.5 m long excavated in a bank. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Considered fairly common throughout range. Habitat appears to be reasonably secure, with overgrazing by livestock as the only obvious potential threat.

**Bibliography.** Carriker (1933), Chebez *et al.* (1999), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Koepcke (1954, 1970), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Mazar Barnett,

On following pages: 15. Buff-breasted Earthcreeper (*Upucerthia validirostris*); 16. Striated Earthcreeper (*Upucerthia serrana*); 17. Rock Earthcreeper (*Upucerthia andaecola*); 18. Straight-billed Earthcreeper (*Upucerthia ruficaudus*); 19. Bolivian Earthcreeper (*Upucerthia harterti*); 20. Chaco Earthcreeper (*Upucerthia certhioides*); 21. Band-tailed Earthcreeper (*Eremobius phoenicurus*); 22. Crag Chilia (*Chilia melanura*).

Clark *et al.* (1998), Parker *et al.* (1982), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Schulenberg (1987b), Stotz *et al.* (1996), Taczanowski (1884), Walker (2001), Zotta (1938).

## 15. Buff-breasted Earthcreeper

### *Upucerthia validirostris*

**French:** Upucerthie fauve **German:** Langschnabel-Erdhacker **Spanish:** Bandurrita Ocrácea  
**Other common names:** Buff-bellied Earthcreeper

**Taxonomy.** *Ochetorhynchus validirostris* Burmeister, 1861, Sierra de Mendoza, Argentina. Closest to *U. jelskii* and *U. albigula*. Has been considered to form a superspecies with former, and may be conspecific; considered together, the two exhibit a stepped cline in plumage coloration (increasingly rufescent to S) and perhaps a smooth cline in measurements, and songs sound very similar (although written descriptions differ somewhat); further study needed. Specimen from S Bolivia (Potosí), allegedly of this species, is evidently indistinguishable from race *pallida* of *U. jelskii*. Two subspecies recognized.

#### Subspecies and Distribution.

*U. v. validirostris* (Burmeister, 1861) - NW Argentina (Salta S to Mendoza and W Córdoba).

*U. v. rufescens* Nares, 1886 - NW Argentina (Sierra de Famatina, in La Rioja).

**Descriptive notes.** 19-21 cm; 30-45 g. Medium-sized, rather plain earthcreeper with long, strongly decurved bill. Has pale buffish-white supercilium, nearly uniform dull brownish-grey crown and upperparts, some paler flecking on forehead; wings like back, large area of rufous at base of remiges; tail nearly square, dark brown, becoming progressively more rufous towards outer feathers; throat greyish-white with faint dull brownish feather tips, upper breast like throat but feather margins more conspicuous, producing slightly scaled appearance, lower breast to undertail-coverts plain light buffish, rear flanks darker;

iris dark brown; bill black, paler base; tarsus and toes blackish to dark brown. Differs from extremely similar *U. jelskii* in having larger, longer bill, more rufous in wings. Sexes alike. Juvenile is faintly barred on crown and back, has more conspicuously marked breast. Race *rufescens* is more rufescent throughout. **Voice.** Song a long dry trill of 10 or more "tyik" notes at c. 5 per second; call a low "ehwit".

**Habitat.** *Puna* grassland mostly at 2700-4000 m, locally down to 2500 m and up to 5000 m; inhabits dry washes and ravines in dense scrub, and shrubby slopes.

**Food and Feeding.** Arthropods; Coleoptera, Diptera and springtails (Collembola) recorded. Usually solitary. Probes in and gleans from ground.

**Breeding.** Breeds during austral summer; eggs from Nov and nestlings in Feb-Mar in Argentina. Presumably monogamous. Nest at end of tunnel c. 0.7-1 m long excavated in bank, or in crevice in rocks, nest-chamber c. 12-13 cm in diameter, floor padded with grasses and a few feathers. Clutch 2 eggs.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Rare to locally fairly common. Habitat occupied is reasonably safe from anthropogenic disturbances, except overgrazing.

**Bibliography.** Araya & Chester (1993), Cabot (1990), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fiora (1933), Fjeldså & Krabbe (1990), Johnson (1967), Koepeke (1970), Mazar Barnett & Pearman (2001), Morrison (1939), Narosky *et al.* (1983), Navas & Bö (1987), Nares (1886), Nares *et al.* (1983), Olrog (1956), de la Peña (1987, 1988), Ridgely & Tudor (1994), Salvador (1992), Stotz *et al.* (1996), Wetmore (1926), Zimmer (1930), Zotta (1938).

## 16. Striated Earthcreeper

### *Upucerthia serrana*

**French:** Upucerthie striée **German:** Streifenerdhacker **Spanish:** Bandurrita Estriada

**Taxonomy.** *Upucerthia serrana* Taczanowski, 1875, Junin and Acancocha, Peru.

Considered by some to form a superspecies with *U. andaecola*. Two subspecies recognized.

#### Subspecies and Distribution.

*U. s. serrana* Taczanowski, 1875 - Andes of N & C Peru (Cajamarca S to Lima and Junin).

*U. s. huancavelicae* Morrison, 1938 - Andes of S Peru (Huancavelica).

**Descriptive notes.** 19-20 cm; 44-52 g. Large, dark earthcreeper, darkest in genus, with strongly decurved bill. Has whitish supercilium, black eyestripe, face grizzled dark brownish and dull buffy whitish; crown and back dull dark brown with faint pale streaks, especially on forehead and hindneck, blending to unstreaked chestnut-brown rump and uppertail-coverts; wings mostly reddish-brown, bases of remiges dark rufous; tail rounded, dark reddish-brown to rufous; chin and throat dull greyish-white with hint of scalloping, breast and belly greyish-brown with conspicuous pale shaft streaks, streaks most prominent on centre of breast, lower flanks and

undertail-coverts slightly more rufescent; iris brown; bill blackish, base of lower mandible whitish; tarsus pale grey, toes darker. Sexes alike. Juvenile has scaled breast and faint barring on upper belly, rest of belly almost unstreaked. Race *huancavelicae* described as darker overall, flanks not so brown. **Voice.** Song a harsh trill introduced by 3 separate notes.

**Habitat.** Arid montane scrub and *Polylepis* woodland on rocky, shrubby slopes; present at elevations of 2750-4300 m.

**Food and Feeding.** Arthropods. Usually forages solitary. Probes in and gleans from ground, and flakes leaf litter; occasionally probes bark low in *Polylepis* trees.

**Breeding.** Nestlings in Oct. Presumably monogamous. One nest found, at end of tunnel c. 35 cm long, presumably excavated by the birds themselves, in sloping bank. Clutch size uncertain, probably 2 eggs.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Peruvian High Andes EBA. Uncommon. Has fairly small geographical range, but habitat occupied is reasonably secure; overgrazing is the only human disturbance.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså (1992b), Fjeldså & Krabbe (1990), Koepeke (1954, 1970), Morrison (1939), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Vuilleumier (1980a), Zimmer (1930).

## 17. Rock Earthcreeper

### *Upucerthia andaecola*

**French:** Upucerthie des rochers **German:** Rostschwanz-Erdhacker **Spanish:** Bandurrita Roquera  
**Other common names:** Rufous-tailed Earthcreeper

**Taxonomy.** *Uppucerthia* [sic] *andaecola* d'Orbigny and Lafresnaye, 1838, Sicasica, La Paz, Bolivia. Considered by some to form a superspecies with *U. serrana*, but plumage features suggest possible closer relationship to *U. ruficaudus*. Monotypic.

**Distribution.** Andes of Bolivia (La Paz S to Potosí), extreme NE Chile (W Antofagasta) and NW Argentina (Jujuy, Salta, N Catamarca).

**Descriptive notes.** 16-18 cm; 28-34 g. Medium-sized earthcreeper with long, slightly decurved bill. Has buff supercilium, dark brownish postocular band, buff lower face; crown and upperparts rich brown, blackish streaking on side of rufous-tinged forehead, uppertail-coverts dark rufous-brown; wings slightly more rufescent than back; tail slightly rounded, dark rufous; throat buffy whitish, breast and belly darker, tinged tawny, prominent dark brownish streaks from sides to flanks that extend on to breast and belly but fade towards centre; undertail-coverts tawny; iris brown; bill blackish, base of lower mandible

pale grey; tarsus and toes dark brown or grey-brown. Sexes alike. Juvenile has scaly breast and belly, pale feather edges on back. **Voice.** Song a piercing "veetveet-veeveeveeveevee-veet-viree-veetveevee"; a variable-length series of whining, querulous, strained whistles possibly the same vocalization. Alarm call a high-pitched, rodent-like, squeaky, whistled "zuwéeét".

**Habitat.** Arid montane scrub; locally in *puna* grassland with rocky arid slopes and ravines with scattered bushes and bunch-grass. At 2600-4000 m, locally to 4500 m.

**Food and Feeding.** Arthropods, which are gleaned and extracted from ground. Usually forages solitary.

**Breeding.** Season evidently during austral summer; eggs, nestlings and fledglings in Nov in Argentina. Presumably monogamous. Nest at end of tunnel c. 0.4-1 m long excavated in bank, or in crevice among rocks, nest-chamber floor 6 cm in diameter, padded with plant fibres, dry grasses and a few feathers. Clutch 2 eggs.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Habitat occupied is reasonably secure, with overgrazing the only human disturbance.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Fjeldså & Majer (1996), Fraga & Narosky (1985), Høy (1980), Johnson (1967), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), de la Peña (1987, 1988), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stotz *et al.* (1996).

## 18. Straight-billed Earthcreeper

### *Upucerthia ruficaudus*

**French:** Upucerthie à bec droit **Spanish:** Bandurrita Piquirrecta  
**German:** Geradschnabel-Erdhacker  
**Other common names:** Meyen's Earthcreeper

**Taxonomy.** *Ochetorhynchus ruficaudus* Meyen, 1834, base of Volcán de Maipú, 10,000 feet [c. 3050 m], Santiago, Chile.

Sometimes included with *U. harterti* and *U. certhioides* in a separate genus *Ochetorhynchus*, but plumage similarities suggest a closer relationship to *U. andaecola*. Differences in coloration of nominate race between N and S extremes (with darker and less reddish upperparts in S) indicate either strong clinal variation or, perhaps, an undescribed race. Three subspecies currently recognized.

#### Subspecies and Distribution.

*U. r. montana* d'Orbigny & Lafresnaye, 1838 - Andes of S Peru (Arequipa to Tacna), Bolivia (La Paz S to Potosí), N Chile (Tarapacá, and probably E Antofagasta) and N Argentina (Jujuy S to Catamarca).

*U. r. famatinae* Nares, 1886 - NW Argentina (Sierra de Famatina, in La Rioja).

*U. r. ruficaudus* (Meyen, 1834) - Andes of W Argentina (San Juan S to S Chubut) and adjacent Chile (S to Santiago).

**Descriptive notes.** 16-19 cm; 28-41 g. Medium-sized earthcreeper with long, very slightly decurved bill. Nominative race has narrow whitish supercilium, black eyestripe, rest of face dull brownish with some paler flammulations; crown brown, slightly mottled, blending to rufescent brown back and rump, with uppertail-coverts dark rufescent (upperparts darker, less reddish, in S of range); wings slightly more rufescent than back, more rufous at base of remiges; tail almost square, central rectrices rufous at base, blending to blackish tips, outer rectrices mostly blackish-brown on inner webs, dark

rufous on outer webs, outer rectrices nearly all rufous; throat and malar area whitish, breast whitish with indistinct diffuse dull brownish streaking, most prominent at sides; belly and flanks pale rufescent brownish, whitish streaking vanishing posteriorly, undertail-coverts tawny; iris brown; bill black or blackish-brown, base of mandible often whitish horn-coloured; tarsus and

toes black or blackish-brown. Sexes alike. Juvenile is tinged rufous throughout, with pale edgings on crown and back feathers. Race *montana* has whiter throat and breast, conspicuously streaked sides and flanks, darker belly; *famatiniae* differs from nominate in slightly darker back, darker flanks and undertail-coverts, more contrasting whiter breast. **VOICE.** Song a fast series of strained, complaining, chattering "pu" notes, rising into 2-3 loud "pee" notes, lasts 10 seconds or more; call a sharp "kweep" or "wheet".

**Habitat.** Arid montane scrub at 1800-4300 m, locally down to 1300 m; inhabits rocky arid slopes and ravines, especially near large boulders, with scattered bushes and bunch-grass.

**Food and Feeding.** Arthropods, gleaned and extracted from ground. Usually forages solitarily.

**Breeding.** Season evidently during austral summer; eggs in Nov-Dec, fledglings in Nov-Jan and nestlings in Feb in Argentina; eggs in Nov-Dec in Chile. Presumably monogamous. Nest at end of tunnel c. 0.5-0.7 m long in rocky crevice or bank, floor of nest-chamber padded with grass, hair and feathers. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout range. Habitat reasonably safe from anthropogenic disturbances, except overgrazing.

**Bibliography.** Araya & Chester (1993), Bond (1945), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), David & Gosselin (2002a), Esteban (1951b), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Johnson (1967), Mazar Barnett & Kirwan (1999a), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas (1971), Nores (1986), Parker *et al.* (1982), de la Peña (1987, 1988), Remsen (2003a), Remsen & Traylor (1989), Ribero (1991), Ridgely & Tudor (1994), Rocha & Quiroga (1996), Salvador (1990), Schulenberg (1987b), Stotz *et al.* (1996), Vuilleumier (1993a), Wetmore & Peters (1949).

## 19. Bolivian Earthcreeper

### *Upucerthia harterti*

**French:** Upucerthie de Bolivie **German:** Blaßbauch-Erdhacker **Spanish:** Bandurrita Boliviana  
**Other common names:** Hartert's Earthcreeper

**Taxonomy.** *Upucerthia harterti* Berlepsch, 1892, Trigal and Valle Grande, Santa Cruz, Bolivia. Sometimes placed in a separate genus *Ochetorhynchus* along with *U. ruficaudus* and *U. certhioides*; closest to latter, with which has been considered to form a superspecies or to be conspecific. Monotypic.

**Distribution.** Andes of Bolivia (S La Paz S to Chuquisaca and Potosi).

**Descriptive notes.** 16 cm; 22-26 g. Small earthcreeper with long, very slightly decurved bill. Has broad buff supercilium extending to forehead, with mostly dark brownish, grizzled loreal area and auriculars; crown dark brown, blending to rich brown on back and rump and to reddish brown on uppertail-coverts; wings like back, bases of remiges dark rufous; tail rounded, rufous-chestnut basally, blending to fuscous brown distally, outer feather pairs brightest, outer rectrix entirely rufous-chestnut; throat and malar area white, rest of underparts pale cinnamon-buff, lower flanks rufescent brown, undertail-coverts dull rufous;

iris brown; upper mandible blackish, lower mandible pale with blackish tip; tarsus and toes brownish-olive or grey. Sexes alike. Juvenile undescribed. **VOICE.** Song a series of 7-15 loud, dry, clear, penetrating "zeet" notes that increase in intensity, descend in pitch, ending in chatter, lasts c. 5 seconds. Call a sharp "bzeeeeeee" or "dzyoot", repeated frequently; also rodent-like, wheezy, piercing whistle, "dzeeaa".

**Habitat.** Arid montane scrub at 1430-3000 m; inhabits slopes with dense scrub and low deciduous woodland, especially where terrestrial bromeliads common.

**Food and Feeding.** Arthropods; recorded dietary items are tiny molluscs. Usually solitary. Food gleaned from and extracted from ground and rock crevices.

**Breeding.** No information. Presumed to breed during austral summer.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in High Andes of Bolivia and Argentina EBA. Uncommon. Habitat subject to overgrazing and clearance for firewood possibly throughout its small geographical range. Nevertheless, this species appears to tolerate moderate to severe disturbance by humans.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Herzog *et al.* (1997), Krabbe *et al.* (1996), Kratter *et al.* (1993), Mazar Barnett *et al.* (1997), Remsen & Traylor (1989), Remsen (2003a), Remsen *et al.* (1988), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore & Peters (1949).

## 20. Chaco Earthcreeper

### *Upucerthia certhioides*

**French:** Upucerthie du chaco **German:** Roststirn-Erdhacker **Spanish:** Bandurrita Chaqueña

**Taxonomy.** *Anabates certhioides* d'Orbigny and Lafresnaye, 1838, Corrientes, Argentina. Sometimes placed in a separate genus *Ochetorhynchus* along with *U. ruficaudus* and *U. harterti*; closest to latter, with which may form a superspecies, or the two may be conspecific. Differs from other congeners for which relevant data available in having pale blue eggs (not white) and more flexible nest-site placement. Racial variation may be partly or entirely clinal, and one or more of the races possibly not tenable; quantitative study of plumage coloration required. Three subspecies recognized.

**Subspecies and Distribution.**

*U. c. estebani* (Wetmore & J. L. Peters, 1949) - extreme SC Bolivia (Santa Cruz), N Argentina (Jujuy and Catamarca E to Chaco and S to Córdoba) and W Paraguay.

*U. c. luscini* (Burnmeister, 1860) - W Argentina (San Juan, La Rioja and W Córdoba S to Mendoza and N San Luis).

*U. c. certhioides* (d'Orbigny & Lafresnaye, 1838) - NE Argentina (E Formosa and C Corrientes S to E Río Negro and SW Buenos Aires).

**Descriptive notes.** 16 cm; 18-31 g. Small earthcreeper with long, very slightly decurved bill. Nominative race has indistinct orange-rufous supercilium, messy dark brown loreal region and auriculars; forehead dull orange-rufous, blending to dull dark brownish crown and back; rump and uppertail-coverts slightly more rufescent; wings slightly more rufescent than back, base of remiges rufous;

tail rounded, rufescent brown, duldest on central feather pair, progressively more rufous towards outer feathers; throat and malar area white, underparts dull brown, rufescent flanks and undertail-coverts; iris brown; upper mandible blackish to dark grey, lower mandible slate-grey to pinkish-grey; tarsus and toes blackish to dark grey. Sexes alike. Juvenile is tinged rufous throughout, rufous of forehead less conspicuous. Race *estebani* is paler on back, duller on breast and belly, lacks rufescent tinge on flanks; *luscini* has greyer, less rufescent upperparts, more extensive rufous on wings, paler underparts. **VOICE.** Song a series

of 5-15 loud, squeaky penetrating "chiqui" notes that increase in intensity, descend in pitch; call a loud whistled "tééoo" or "tuéét".

**Habitat.** Deciduous woodland and dense Chaco scrub, especially near terrestrial bromeliads; to 1800 m. In W Argentina, found up into Andes, where it occupies dense shrubby slopes similar to those used by *U. harterti* in Bolivia.

**Food and Feeding.** Arthropods; Orthoptera, Coleoptera and Diptera all recorded as forming part of diet. Usually forages solitarily. Items gleaned from ground, possibly also from low vegetation.

**Breeding.** Breeds during austral summer; eggs recorded in Oct-Feb and nestlings in Oct-Nov in Argentina. Presumably monogamous. Nest variable, stick nest built in bush or low tree, or placed in cavity or crevice in tree trunk, rocks or building, or old nest of *Furnarius* used; floor of nest-chamber thickly padded with hair, grasses, lichens, plant fibres, snake skins, and even bits of human refuse. Clutch 3-4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in much of its range. Occurs in Chancani Natural Reserve, in Argentina.

**Bibliography.** Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Fraga & Narosky (1985), Hartert & Venturi (1909), Hayes (1995), Kratter *et al.* (1993), Mazar Barnett & Pearman (2001), Narosky (1975b), Narosky & Di Giacomo (1993), Narosky *et al.* (1983), Navas & Bó (1987), Nellar (1993), Nores *et al.* (1983), Ochoa (1971), Olrog (1963a), Partridge (1953), de la Peña (1987, 1988, 1997), Remsen (2003a), Ridgely & Tudor (1994), Salvador (1988), Short (1975), Stotz *et al.* (1996), Wetmore (1926), Wetmore & Peters (1949), Zotta (1940).

## Genus EREMOBIUS Gould, 1839

### 21. Band-tailed Earthcreeper

#### *Eremobius phoenicurus*

**French:** Upucerthie rougequeue **German:** Schwarzwand-Erdhacker **Spanish:** Bandurrita Patagónica

**Taxonomy.** *Eremobius phoenicurus* Gould, 1839, Port Desire, San Julián and Santa Cruz, east coast of Patagonia, Argentina.

Morphology suggests closest relationship to genus *Upucerthia*, but nest type is very different; considered by some authors to be closer to *Cinclodes*. Nest structure, however, suggests possible relationship to such genera as *Phacellodomus*, *Synallaxis*, *Pseudoseisura* and *Asthenes*, and plumage coloration, especially tail pattern, vaguely recalls those of some species in *Asthenes*. Monotypic.

**Distribution.** SW Argentina (Neuquén and Río Negro S to Santa Cruz) and extreme S Chile (NE Magallanes).

**Descriptive notes.** 16-17 cm; 28-34 g. Small earthcreeper with thin, straight, medium-length bill. Has white supercilium, dark eyestripe, more rufescent auriculars; crown and upperparts, including most of wings, uniform dull grey-brown; tail rounded, central rectrices mostly fuscous blackish, dull grey-brown at base, other rectrices with dark rufous base sharply demarcated from blackish distal portion, blackish progressively decreasing in extent towards outer feathers; throat whitish, greyer laterally, underparts pale dull grey-brown, distinct paler streaks on breast and flanks, undertail-coverts whitish; iris dark

brown; bill black or blackish-brown, base of lower mandible pale horn or greyish; tarsus and toes blackish-brown or blackish. Sexes alike. Juvenile has pale feather tips on forehead, unstreaked or only faintly streaked breast and belly. **VOICE.** Song a fast dry trill that sometimes ends with separate sharp "ti" notes; alarm a repeated, husky "suwee" or "wheet".

**Habitat.** Arid lowland scrub and temperate grassland, to 1200 m. Inhabits sparsely vegetated plains, plateaux and slopes; often associated with thorny *Monthea* shrubs.

**Food and Feeding.** Arthropods. Usually forages solitarily. Probes and gleans for food items in ground, grass clumps, cushion-plants, also in rock crevices.

**Breeding.** Breeds during austral summer; eggs recorded in Sept and nestlings in Jan. Presumably monogamous. Nest a large oval mass (c. 55 × 30 cm) of interwoven thorny twigs, side entrance with tunnel c. 25 cm long leading to rounded nest-chamber c. 12 cm in diameter, floor of which an interwoven mat of fine grasses, topped with layer of hair, spider webs, dried flowers and feathers; placed c. 1-2 m above ground near top of low bush (often *Monthea*, also *Schinus*, *Condalia*, or spiny cactus). Clutch 2-4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Habitat within its range appears to be reasonably secure, with overgrazing probably the only form of anthropogenic disturbance.

**Bibliography.** Anon. (2003d), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1978), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas

(1971), Olrog (1963a), de la Peña (1988), Peters (1923), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1980a, 1993a), Vuilleumier *et al.* (1993), Wetmore (1926), Zapata (1967).

Genus *CHILIA* Salvadori, 1908

22. Crag Chilia

*Chilia melanura*

**French:** Chilia des rochers      **German:** Rotbürzel-Erdhacker      **Spanish:** Chiricoca  
**Other common names:** Mountain Tococo

**Taxonomy.** *Enicornis melanura* G. R. Gray, 1846, no locality = Chile. Generally considered most closely related to *Eremobius* and *Upucerthia*, but has also been thought to be closest to *Cinclodes*. Two subspecies recognized.

**Subspecies and Distribution.**  
*C. m. atacamae* Hellmayr, 1925 - NC Chile (Atacama, Coquimbo).

*C. m. melanura* (G. R. Gray, 1846) - C Chile (Aconcagua S to Colchagua).

**Descriptive notes.** 18-19 cm; 31-40 g. Very straight bill. Nominate race has narrow whitish supercilium, dark brown lores and auriculars fringed whitish along lower edge; mostly darkish brown above, contrasting rufous rump and uppertail-coverts; extensive rufous wingband; tail mostly blackish-brown, rufous at base and on outer web of outer rectrix; throat whitish, breast dull smoky greyish, belly dull brown, flanks and undertail-coverts rufous; iris brown; upper mandible blackish, lower mandible pale grey with blackish tip; tarsus and toes blackish. Sexes alike. Juvenile has

pale edgings on back feathers, indistinct bars on underparts. Race *atacamae* is paler and more sandy, whiter supercilium often more distinct, upperwing-coverts greyish-brown instead of dusky brown, breast pale greyish with white streaking, flanks paler brown, bill narrower and shorter. **VOICE.** Song a short (1 second) staccato chatter of jumbled notes with 4-7 loud “teet” notes in middle; call a metallic, abrupt “ch” or “ch-ch”, often given as continuous chatter.

**Habitat.** Arid montane scrub; on steep, rocky slopes and cliffs with little or scattered clumps of vegetation, at 1400-3000 m; also arid low-

land scrub in winter.

**Food and Feeding.** Arthropods, some seeds. Usually solitary. Probes and gleans rocks and crevices for food items.

**Breeding.** Season presumed to be during austral spring-summer; eggs in Sept-Oct. Presumably monogamous. Nest a bulky globular mass of dry sticks, lined with feathers, placed in cavity under rock, occasionally in hole in cactus or earth bank. Clutch 3-4 eggs.

**Movements.** Mainly resident; downslope movements in winter.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Central Chile EBA. Uncommon to fairly common. Occurs in Cerro La Campana National Park. Habitat occupied is fairly remote, and appears therefore to be relatively immune to direct anthropogenic disturbance.

**Bibliography.** Araya & Chester (1993), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Johnson (1967), Marin (2003), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1980a), Zyskowski & Prum (1999).

PLATE 13

inches 3  
cm 8

# Genus *CINCLODES* G. R. Gray, 1840

## 23. Stout-billed Cinclodes

### *Cinclodes excelsior*

**French:** Cinclode du paramo **German:** Schuppenbrust-Uferwipper **Spanish:** Remolinera Ecuatoriana  
**Other common names:** Short-billed/Paramo Cinclodes

**Taxonomy.** *Cinclodes excelsior* P. L. Selater, 1860, Mount Chimborazo, 14,000 feet [c. 4270 m], Ecuador.

Sometimes placed in genus *Geositta*, and in the past in *Upucerthia*, but plumage, wing-raising display and foraging behaviour favour inclusion in present genus. Formerly treated as conspecific with *C. aricomae*, but differs in, especially, plumage and in micro-habitat use. Two subspecies recognized.

#### Subspecies and Distribution.

*C. e. columbianus* (Chapman, 1912) - C Andes of Colombia (Tolima).

*C. e. excelsior* P. L. Selater, 1860 - Andes from extreme SW Colombia (Nariño) S to S Ecuador (N Azuay).

**Descriptive notes.** 20-21 cm; 62-66 g. Large cinclodes with thick-based decurved bill, relatively short tail. Has long whitish supercilium extending from forehead to hindneck, dark brown face with some narrow pale shaft streaks; crown very dark brown, back to uppertail-coverts dark brown; wings dark brown, blackish-brown primary coverts, rufous bases of remiges and edges of tertials; tail rounded, dark brown, with increasing amount of dull rufous towards outer feather pairs; throat and malar area whitish with some faint scalloping, upper breast light brown with diffuse paler scalloping, lower breast and

undertail-coverts brownish with faint pale shaft streaks, flanks brown with pale shaft streaks, belly pale greyish-brown; iris brown to dark brown; bill black; tarsus and toes brownish-grey to blackish. Sexes alike. Juvenile has more mottled breast. Race *columbianus* is slightly darker above and paler below, rufous wingband more distinct. **Voice.** Song a high-pitched, trilled "tr-r-r-r-r-r-ree". Call a nasal "kiu" or "druut" or "ken-ee"; low twittering notes in flight.

**Habitat.** Rocky páramo grassland and semi-humid and humid montane scrub, usually near water or boggy meadows, but also in some barren areas with scattered bushes; also *Polylepis* groves. Occurs from 3200 m up to snow-line, to 5200 m. May require volcanic areas for nest-tunnel excavation.

**Food and Feeding.** Invertebrates, occasionally small vertebrates (small frogs); also some seeds. Forages solitarily or in pairs. Probes and digs in mud, moist soil and debris; occasionally gleans items from low foliage.

**Breeding.** Eggs in Nov in C Colombia; fledglings in Dec in Ecuador. Presumably monogamous. Wing-raising display while singing. Nest a thin layer of decayed vegetable matter at end of gently upward-sloping tunnel 0.7-1.1 m long, excavated in steep bank or road cutting, entrance mostly within 1 m of top of bank and often somewhat protected by overhanging vegetation, no noticeable chamber; in C Colombia prefers to excavate in pumiceous soil strata, which are more porous and friable than other soil types. Clutch probably 2 eggs.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Central Andean Páramo EBA. Uncommon to locally common. Occurs in Cotopaxi National Park and Las Cajas National Recreation Area, in Ecuador.

**Bibliography.** Anon. (2003g), Bond (1945), Carriker (1932), Chapman (1926), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså *et al.* (1987), Graves & Arango (1988), Hilty & Brown (1986), Meyer de Schauensee (1945), Parker *et al.* (1982), Remsen & T aylor (1989), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd (1948b), Vuilleumier (1980a).

## 24. Royal Cinclodes

### *Cinclodes aricomae*

**French:** Cinclode royal **German:** Weißkehl-Uferwipper **Spanish:** Remolinera Real

**Taxonomy.** *Upucerthia aricomae* Carriker, 1932, Aricoma Pass, 15,000 feet [c. 4570 m], Carabaya, Puno, Peru.

Has been placed in *Geositta*, but plumage and behaviour like those of present genus. Formerly treated as race of *C. excelsior*; justification for species rank rather weak, primarily plumage and micro-habitat differences. Monotypic.

**Distribution.** Very locally in Andes of S Peru (Aurimac, Cuzco, Puno) and W Bolivia (La Paz).

**Descriptive notes.** 20-21 cm; 50 g. Large cinclodes with thick-based decurved bill, relatively short tail. Has pale buffish supercilium from forehead to nape; crown, face and upperparts dark brown, bases of remiges rufous bordered with black, tail blackish; throat and malar area whitish with thin dark bars, underparts dark brown, breast broadly streaked whitish; iris dark brown to brown; bill black; tarsus and toes dark pinkish-grey to black. Differs from *C. excelsior* in darker back, considerably darker underparts, more buffy supercilium, blackish tail, more distinct wingband. Sexes alike. Juvenile undescribed. **Voice.** Song a very loud trill.

**Habitat.** Boggy areas next to steep rocky slopes in relatively humid *Polylepis-Gynoxis* woodland; 3500-4600 m.

**Food and Feeding.** Mostly invertebrates; Coleoptera (including Curculionidae) recorded. Small vertebrates (small frogs) occasionally taken; sometimes seeds. Solitary or in pairs. Probes among

rocks encrusted with mosses and lichens, in decaying wood, and in mossy ground in boggy areas; flakes off pieces of moss; also gleans invertebrates from surfaces.

**Breeding.** No precise information available. Season thought to begin in Dec; in Cordillera Vilcanota, pairs are territorial during austral winter. Suggested mean territory size c. 3-4 ha.

#### Movements. Resident.

**Status and Conservation.** CRITICAL. Known from only six localities; global population may total only a few hundred individuals. Threatened by clearance of *Polylepis* woodland, which has already disappeared from

one site (the type locality). Two localities are in officially protected areas in Bolivia, these being Puina, in Madidi National Park, and Ilampu Valley, in Cotapata National Park, but both of these are vulnerable to grazing and burning. Remaining patches, in Peruvian departments of Cuzco and Apurimac, are still being cleared by burning to improve pastures, and degraded by cutting for firewood; they receive no official protection. The species was undoubtedly much more widely distributed at one time; evidence is mounting that humid *Polylepis* woodland has been reduced dramatically during the last few thousand years of human exploitation.

**Bibliography.** Anon. (2003h), Bond (1945), Carriker (1932), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Engblom *et al.* (2002), Fjeldså (1987, 1991), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Fjeldså *et al.* (1987), Kessler (1995), Kessler & Driesch (1994), Parker & O'Neill (1980), Parker *et al.* (1982), Remsen & T aylor (1989), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Valqui (2000), Vogel & Davis (2002), Walker (2001), Wege & Long (1995).

## 25. Bar-winged Cinclodes

### *Cinclodes fuscus*

**French:** Cinclode brun **German:** Kurzschnabel-Uferwipper **Spanish:** Remolinera Común  
**Other common names:** Dusky Cinclodes

**Taxonomy.** *Anthus fuscus* Vieillot, 1818. "Less rare in the fields of Montevideo and Buenos Aires than in Paraguay."

Has been thought by some to form a superspecies with *C. comechingonus* and *C. pabsti*; often treated as conspecific with former, their breeding ranges evidently not overlapping. Sometimes considered also to include *C. olrogii* as a race, that taxon being very similar to races *riojanus* and *yzurietae* of present species. Proposed race *paramo* (from Nariño, in SW Colombia) described as differing from *oreobates* in having shorter wings and tail, but overlap in measurements is extensive. Further, within area assigned to race *albiventris*, plumage varies clinally from darker in N to paler in S; also, birds from drier areas are whiter than those from humid slope of Andes, and are potentially the "true" representatives of that race, leaving presumably the name *longipennis* (proposed for N populations) available for humid-slope birds; described race *rivularis*, of Junin region of Peru, supposedly differs from latter in less rufescent back, paler flanks and less heavily margined breast feathers, which matches some specimens from Junin region, but its type locality (Maraynioc) is at or near humid E slope; whether these two described forms are valid entities requires further study. Nine subspecies recognized.

#### Subspecies and Distribution.

*C. f. oreobates* Scott, 1900 - Colombia in Santa Marta Mts and E & C Andes (N Boyacá S to S Cundinamarca, and Cauca S to Nariño), and Andes of SW Venezuela (S Táchira); possibly also NW Ecuador (Carchi).

*C. f. heterurus* Madarász, 1903 - Andes of W Venezuela (S Lara, Trujillo, Mérida).

*C. f. albidiventris* P. L. Selater, 1860 - N Ecuador (S from Imbabura, possibly from Carchi) S to N Peru (Piura, Cajamarca).

*C. f. albiventris* (R. A. Philippi [Krumwiede] & Landbeck, 1861) - Andes from N Peru (Amazonas) S to Bolivia, N Chile (S to Antofagasta) and NW Argentina (Jujuy S to La Rioja).

*C. f. tucumanus* Chapman, 1919 - NW Argentina (Tucumán).

*C. f. rufus* Nares, 1886 - NW Argentina (Campo de Arenal, in Catamarca).

*C. f. yzurietae* Nares, 1886 - NW Argentina (Sierra del Manchao, in SE Catamarca).

*C. f. riojanus* Nares, 1886 - NW Argentina (Sierra de Famatina, in La Rioja).

*C. f. fuscus* (Vieillot, 1818) - breeds C & S Chile (S from Atacama) and C & S Argentina (Mendoza S to Tierra del Fuego); migrates to S Brazil, SE Paraguay, Uruguay and N Argentina (N to Corrientes).

**Descriptive notes.** 15-19 cm; 24-35 g. Small cinclodes with relatively short bill. Nominale race has conspicuous light buffish-white supercilium, speckled forehead, dark grey-brown auriculars with paler shaft streaks; crown dark grey-brown, upperparts dark brown, wing-coverts with broad buffish edges; dark fuscous remiges, tawny-rufous patch at base forming narrow wingband; tail slightly rounded to nearly square, central rectrices like upperparts, rest blackish-brown, outer three pairs with progressively larger pale tawny tips, outer web of outer rectrix all pale dull tawny; malar area bright white, flared posteriorly, blending into pale

tawny side of neck; chin white, throat white with thin dark scalloping, breast dull pale brown with faint buff shaft streaks, belly whitish-buff, flanks extensively dull brown, undertail-coverts mottled dull brown and buff; iris brown or dark brown; bill dark brown to blackish, often paler base of lower mandible; tarsus and toes blackish to dark brownish. Sexes alike. Juvenile is more richly coloured, most feathers on underparts with dark edging. Races tend to be more brownish than nominate, lacking obvious greyish tones dorsally; *yzurietae* has darker brown upperparts, especially crown, and much whiter breast; *rufus* differs from others in having more rufescent upperparts, more ochraceous belly, more rufescent flanks, richer brown wings and tail; *riojanus* is darker chocolate-brown above and browner on breast than other races, especially last; *tucumanus* resembles previous but has more

reddish back, paler underparts, deep buff wingband; *albiiventris* has reddish tinge above, whitish underparts, with wingband paler, almost white, undertail-coverts white; *albidiventris* has dark back with even more reddish tones, brighter outer webs of outer rectrices, deep cinnamon wingband, browner breast with more conspicuous pale markings, buff underwing-coverts; *oreobates* resembles previous, but less rufescent above, paler wingband and webs of outer rectrices, supercilium less buffy, throat more spotted, underparts whiter; *heterurus* differs from last in having outer three rectrices almost entirely bright cinnamon, middle rectrices more rufescent, wingband deeper cinnamon. VOICE. Song a short, fast, dry trill, "t-r-r-r-r-r-r-r-r-r", lasting c. 2 seconds, often introduced by call notes, given from rock or ground, sometimes in flight. Call a sharp "pfip", sometimes doubled; also series of high-pitched tinkling notes; flight call a sharp whistled "tsip".

**Habitat.** *Páramo* grassland, *puna* grassland, southern temperate grassland, arid montane scrub; variety of open, grassy habitats, from *páramo* and *puna* grassland to Patagonian steppes and beaches, usually near water, especially bogs and streams. Common around human habitations. Sea-level to 5000 m.

**Food and Feeding.** Invertebrates; also seeds. In detailed analysis of stomach contents of birds from a river island in Argentina during austral winter, diet found to be strongly dominated by aquatic invertebrates, with chironomid midges (*Chironomus domizii*) forming 60% of all organisms identified, also many molluscs (Planorbidae); seeds, mainly of grasses and Compositae, also strongly represented, accounting for 23% of total food items; only other items represented by more than two individuals were weevils (Curculionidae). Additional prey recorded include Coleoptera of families Dytiscidae, Hydrophilidae, Carabidae, Chrysomelidae, Tenebrionidae, also Hemiptera (e.g. Reduviidae), wasps (Vespidae), ants (*Pheidole*), lepidopteran larvae, various flies (Diptera), snails (*Littoridina*). Forages singly or in pairs. Runs or hops rapidly. Gleans from or probes in ground, mud, shallow water, rocks, beach debris, grass, and dung.

**Breeding.** Breeds during austral spring-summer in S portions of range, but timing uncertain towards equator; eggs in Sept-Jan in S Peru, Chile and Argentina, and in Apr in Bolivia; fledglings in Feb in N Colombia, Mar in N Ecuador, and Nov-Jan in S Ecuador, Peru and Chile. Monogamous. Wing-flapping display while singing from perch. Nest at end of tunnel 0.4-1 m long excavated in embankment, or in crevice in rocks or hole in wall of building or other structure, nest-chamber with pad c. 8 cm wide of grasses and some hair. Clutch 2-3 eggs.

**Movements.** Most populations largely resident; some downslope movement in winter or during bad weather. Nominate race largely migratory, populations migrating N or moving to lower altitudes after breeding.

**Status and Conservation.** Not globally threatened. Common and widespread throughout most of range; the commonest member of genus in many places. In many areas occupied by this species, its habitats are subject to, at most, only minimal anthropogenic disturbance; probably benefits from effects of grazing.

**Bibliography.** Anon. ## 26. Cordoba Cinclodes

### *Cinclodes comechingonus*

**French:** Cinclode gris **German:** Rostspitzen-Uferwippen **Spanish:** Remolinera de Córdoba  
**Other common names:** Chestnut-winged/Comechingones/Sierran Cinclodes

**Taxonomy.** *Cinclodes comechingonus* Zotta and Gavio, 1944, Sierras de Comechingones, 2400 m, 7 km west of La Paz, Córdoba, Argentina.

Has been thought by some to form a superspecies with *C. fuscus* and *C. pabsti*; often treated as conspecific with former, with no evident overlap in breeding ranges. Monotypic.

**Distribution.** NC Argentina (Córdoba, NE San Luis, and recently found in Mendoza); in non-breeding season occurs N to E Tucumán and N Santiago del Estero.

**Descriptive notes.** 17 cm; 25-32 g. Has buff-white supercilium, dark grey-brown band from lores to rear auriculars; crown and upperparts grey-brown; breast dark rufous band on base of remiges outlined in black; tail nearly square, dark grey, outer feather pairs blackish with pale rufous tips; throat white, flanks light brown, rest of underparts pale buff-white, throat and breast with dark scalloping; iris brown; bill black, yellowish base of lower mandible; tarsus and toes black. Distinguished from similar *C. fuscus* by broader, more rufous wingband (brighter and more extensive than in all other congeners), greyer upperparts, paler under-

parts, yellow on bill. Sexes alike. Juvenile undescribed. VOICE. Song a trill, evidently more complex than that of *C. fuscus* but further study required.

**Habitat.** Open grassy areas, often rocky, at 1600-2800 m; recently found up to 3300 m in vicinity of Aconagua. Not so closely tied to water as are other members of genus.

**Food and Feeding.** Reported food items are weevils (Curculionidae), Hemiptera, Lepidoptera (*Colias*), also hydrobiid snails (*Littoridina*) and molluscs (*Sphaerium*); also seeds. Usually in pairs. Gleans invertebrates from ground, grass and rocks.

**Breeding.** Season during austral spring-summer; eggs in Nov-Dec, nestlings in Nov and fledglings in Jan. Monogamous; reported to remain paired throughout year. Nest at end of tunnel c. 0.5 m long excavated in bank, or in crevice in rocks, nest-chamber padded with grasses, hairs and leaves. Clutch 2 eggs.

**Movements.** Parts of the population descend to lower elevations (to 1000 m) or migrate N after breeding.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Sierras Centrales de Argentina EBA. Common within limited range. Habitat occupied by this species is relatively free from human disturbance other than grazing.

**Bibliography.** Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Chesser (1994), Esteban (1951b), Fjeldsá & Krabbe (1990), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Navas &

Camperi (1999), Nellar (1993), Nores & Yzurieta (1981), Nores *et al.* (1983), Olrog (1963a), de la Peña (1987, 1988), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Vuilleumier (1980a), Zotta & Gavio (1944).

## 27. Long-tailed Cinclodes

### *Cinclodes pabsti*

**French:** Cinclode à longue queue **Spanish:** Remolinera Colilarga  
**German:** Santa Catarina-Uferwippen  
**Other common names:** Pabst's Cinclodes

**Taxonomy.** *Cinclodes pabsti* Sick, 1969, between Tainhas and Taimbézinho, 16 km north-east of Tainhas along road to Cambaré, c. 1000 m, Rio Grande do Sul, Brazil.

Plumage similarities and biogeography suggest that closest relationship is with *C. fuscus*. Has been thought by some to form a superspecies with that and with *C. comechingonus*. Monotypic.

**Distribution.** Extreme SE Brazil (SE Santa Catarina, NE Rio Grande do Sul).

**Descriptive notes.** 21-22 cm; 49-55 g. Large cinclodes with fairly long, straight bill, relatively long tail. Has long and conspicuous white supercilium, dark band from lores to rear auriculars; greyish-brown above, crown slightly darker than back; two indistinct but broad cinnamon-buff wingbars and wingband; tail dark brown, tips of outer rectrices buff or ochraceous; throat white, contrasting with pale yellowish buffy-brown underparts; iris brown; bill black, sometimes pale base of lower mandible; tarsus and toes grey to black. Sexes alike. Juvenile undescribed. VOICE. Song a prolonged trill, increasing in volume towards end, given

from perch or in flight; call a descending "iseeo".

**Habitat.** Southern temperate grassland, also pastures and agricultural land; open grassland, often rocky and often near houses, usually near water; 750-1700 m.

**Food and Feeding.** Arthropods and presumably other invertebrates, gleaned from ground, grass, and water's edge. Forages singly or in pairs.

**Breeding.** Breeds during austral spring-summer; nestlings in Sept and Nov-Dec. Presumably monogamous. Nest a platform of grass and feathers placed in rock crevice, or at end of tunnel excavated in embankment, usually in hard, rocky soil, occasionally in hole in house. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Atlantic Forest Mountains EBA. Uncommon to fairly common within its small geographical range; uncommon in Aparados da Serra National Park. Evidently maintains reasonably healthy populations in areas subjected to moderate human disturbance.

**Bibliography.** Belton (1984), Chesser (1994), Cordeiro (2001), Mayr & Vuilleumier (1983), Parker & Goerck (1997), Pinto (1978), Ridgely & Tudor (1994), Sick (1969b, 1973, 1985d, 1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 28. Olrog's Cinclodes

### *Cinclodes olrogi*

**French:** Cinclode d'Olrog **German:** Zweifarb-Uferwippen **Spanish:** Remolinera de Olrog

**Taxonomy.** *Cinclodes olrogi* Nores and Yzurieta, 1979, Pampa de Achala, Sierras Grandes de Córdoba, 2200 m, Argentina.

Has been thought to form a superspecies with *C. oustaleti*. Considered conspecific with latter by some authors and with *C. fuscus* by others, but plumage rather distinctive; further research needed. Monotypic.

**Distribution.** NC Argentina in W Córdoba (Sierras Grandes, Sierras de Comechingones) and NE San Luis (Sierras de San Luis).

**Descriptive notes.** 17 cm; 24-32 g. Small, fairly dark cinclodes with medium-length, slightly decurved bill. Has white supercilium, blackish-brown crown, lores and auriculars; upperparts dark grey-brown with faint chestnut tinge; wings darker, striking white band across base of remiges; tail dark grey-brown, darker at sides, tips of outer rectrices dull rufous; throat and breast white, some dark scaling on breast, rest of underparts pale dull brown; no information on bare-part colours, probably all dark brown to blackish. Sexes alike. Juvenile undescribed. VOICE. No information.

**Habitat.** Open grassy and rocky areas, usually near streams and lakes; 1600-2800 m.

**Food and Feeding.** Arthropods and presumably other invertebrates, gleaned from ground, rocks and mud. Solitary or in pairs.

**Breeding.** Breeds during austral spring-summer; eggs and nestlings in Nov-Dec. Presumably monogamous. Nest at end of tunnel c. 0.3-0.5 m long excavated in bank, or in rock crevice or in hole in structure, nest-chamber with pad c. 6 cm wide of plant fibres and hair. Clutch 2 eggs.

**Movements.** Mainly resident; some post-breeding downslope movement, to 900 m.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Sierras Centrales de Argentina EBA. Common within its small geographical range. Habitat occupied is relatively free from human disturbance; grazing appears to be the only potential problem.

**Bibliography.** Canevari *et al.* (1991), Chebez *et al.* (1999), Fjeldsá & Krabbe (1990), Narosky *et al.* (1983), Navas & Bó (1987), Nellar (1993), Nores (1986), Nores & Yzurieta (1979a), Nores *et al.* (1983), de la Peña (1987), Ridgely & Tudor (1994), Stotz *et al.* (1996), Stattersfield *et al.* (1998), Vuilleumier & Mayr (1987).

## 29. Grey-flanked Cinclodes

### *Cinclodes oustaleti*

**French:** Cinclode d'Oustalet **German:** Graufanken-Uferwippen **Spanish:** Remolinera Chica  
**Other common names:** Oustalet's Cinclodes

**Taxonomy.** *Cinclodes oustaleti* Scott, 1900, Valparaíso, central Chile. Has been thought to form a superspecies with *C. olrogii*. Plumage similarities, however, suggest that it may be most closely related to *C. patagonicus* or to the superspecies formed by *C. taczanowskii* and *C. nigrofumosus*. Three subspecies recognized.

**Subspecies and Distribution.**

*C. o. oustaleti* Scott, 1900 - Chile (Antofagasta S to Aisén) and W Argentina (Mendoza S to W Chubut).

*C. o. baekstroemii* Lönnberg, 1921 - Juan Fernández Is, off C Chile.

*C. o. hornensis* Dabbene, 1917 - breeds on Desolación I (S Chile), Tierra del Fuego and Cape Horn Archipelago; some migrate N to S Argentina and C Chile.

**Descriptive notes.** 17-18 cm; 22-31 g. Small, dark cinclodes with medium-length, slightly decurved bill. Nominat race has buff supercilium, speckled at front, blackish-brown loreal area and auriculars; crown dark greyish-brown, upperparts rich dark brown; wings dark brown like back, whitish bend of wing, tawny-rufous and blackish-brown primary coverts, some rufous at base of remiges; tail slightly rounded to nearly square, blackish-brown, small rufous tips of outer rectrices; throat and malar area whitish with dark scalloping, breast dull dark grey-brown, fairly conspicuous pale shaft spots on upper breast, becoming short and faint streaks

on lower breast, belly paler and browner, whitish centrally, flanks and undertail-coverts rich dark brown with some whitish tips; iris dark brown to black; bill blackish or blackish-horn; tarsus and toes blackish-brown. Sexes alike. Juvenile undescribed. Race *hornensis* is darker grey above, much less richly coloured, also greyer and less brown below, especially on flanks; *baekstroemii* is tinged rufous on sides, flanks and undertail-coverts. VOICE. Song apparently undescribed.

**Habitat.** Open grassy and rocky areas, from sea-level to 4200 m. In montane areas, often found near streams.

**Food and Feeding.** Arthropods and presumably other invertebrates, gleaned from ground, grass and rocks. Forages singly or in pairs.

**Breeding.** Breeds during austral spring-summer; eggs in Oct in S Chile, and nestlings in Oct in CW Argentina. Presumably monogamous. Nest at end of tunnel excavated in bank or in crevice in rocks, often overlooking stream, nest-chamber with pad of grasses and hair. Clutch 2-3 eggs.

**Movements.** Many populations apparently resident, but much downslope movement in winter. S race *hornensis* at least partially migratory, some moving N after breeding, with records to S Argentina (Chubut) and C Chile (Chiloé, Cautín, Concepción).

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Occurs in Vicente Pérez Rosales National Park, in Chile, and in Tierra del Fuego National Park, in Argentina. Habitat occupied is subject to only minimal human disturbance other than grazing.

**Bibliography.** Anon. (2003d), Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Chesser (1994), Contreras (1975), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Humphrey *et al.* (1970), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Navas & Camperi (1999), Olrog (1948, 1963a), de la Peña (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996), Wetmore (1926), Zotta (1938).

## 30. Dark-bellied Cinclodes

### *Cinclodes patagonicus*

**French:** Cinclode à ventre sombre

**Spanish:** Remolinerá Araucana

**German:** Streifenbrust-Uferwippler

**Other common names:** Patagonian Cinclodes

**Taxonomy.** *Motacilla patagonica* J. F. Gmelin, 1789, Tierra del Fuego.

Plumage similarities suggest that it is most closely related to *C. taczanowskii*, *C. nigrofumosus* and *C. antarcticus*. Race *chilensis* poorly differentiated, possibly not diagnosable. Two subspecies recognized.

**Subspecies and Distribution.**

*C. p. chilensis* (Lesson, 1828) - SC Chile (Aconcagua S to N Aisén) and W Argentina (Mendoza S to N Santa Cruz).

*C. p. patagonicus* (J. F. Gmelin, 1789) - S Chile (from NC Aisén) and S Argentina (from S Santa Cruz) S to Tierra del Fuego.

**Descriptive notes.** 18-20 cm; 37-54 g. Fairly large, dark cinclodes with long, slightly decurved bill. Nominat race has conspicuous white supercilium extending narrowly to forehead, very dark brown loreal area and auriculars, latter with some narrow whitish shaft streaks; crown very dark brown, upperparts slightly paler; wings dark brown, blackish-brown primary coverts, some pale rufous-tinged white at base of remiges; tail slightly rounded, dark brown, outer three feather pairs with tawny-whitish tips increasing in extent laterally; malar area white with some dark speckling, throat whitish with faint flecking, underparts dull

dark brown, conspicuous pale shaft spots on upper breast, becoming long streaks on lower breast and upper belly, lower belly more or less unmarked, undertail-coverts with whitish tips; iris dark brown; bill, tarsus and toes brown to blackish. Sexes alike. Juvenile has pale-edged back feathers, broader and more diffuse streaks below restricted to breast. Race *chilensis* has tips of outer rectrices more buffy, underparts browner, reduced streaking on belly. VOICE. Song a long, complex series of musical notes and trills; call a sharp "tjit", sometimes in series.

**Habitat.** Coastal rocky beaches, shores of lakes, rivers, and streams; sea-level to 2500 m.

**Food and Feeding.** Invertebrates, gleaned from ground, rocks, beach debris and edge of water. Forages solitarily or in pairs.

**Breeding.** Season evidently during austral spring-summer; eggs recorded in Sept-Jan, nestlings in Dec and fledglings in Nov-Jan. Presumably monogamous. Wing-raising display while singing. Nest at end of tunnel c. 1 m long excavated in bank, or in abandoned burrow, in hole or crevice in rocks or hollow log, or in hole or ledge in building or other structure, nest-chamber with pad of grass and feathers. Clutch 2-3 eggs.

**Movements.** Mostly resident; some downslope movement in winter. Apparently leaves Tierra del Fuego after breeding, but S limit of all-year range uncertain.

**Status and Conservation.** Not globally threatened. Fairly common and widespread throughout range. Occurs in Vicente Pérez Rosales and Nahuelbuta National Parks, in Chile, and in Tierra del Fuego National Park, in Argentina. Able to exploit a variety of water-edge habitats, and not thought likely to become threatened in the near future.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1975), Cory & Hellmayr (1925), Esteban (1951b), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Humphrey *et al.* (1970), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parmelee & Rasmussen (1994), de la Peña (1988), Philippi *et al.* (1954), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1985).

## 31. Surf Cinclodes

### *Cinclodes taczanowskii*

**French:** Cinclode de Taczanowski

**Spanish:** Remolinerá Costera Peruana

**German:** Nördlicher Felsuferwippler

**Other common names:** Peruvian Seaside/Taczanowski's Cinclodes

**Taxonomy.** *Cinclodes taczanowskii* Berlepsch and Stolzmann, 1892, Chorillos, near Lima, Peru. Forms a superspecies with *C. nigrofumosus* and may be conspecific; no indication that difference between the two is any greater than that found among races of e.g. *C. fuscus*. Monotypic.

**Distribution.** Coast of C & S Peru (Ancash S to Tacna).

**Descriptive notes.** 21-22 cm; 62-67 g. Large, dark cinclodes with relatively short, straight bill. Has hint of indistinct brown supercilium; rest of face dark brown with pale shaft streaking, crown blackish-brown, faint brown shaft spots on forehead and streaks on rest of crown; back dull dark brown, rump and uppertail-coverts slightly paler; wing-coverts dark brown with pale brown tips, remiges fuscous to blackish with pale rufous and whitish edgings at bases (dull wingband); tail rounded, blackish-brown, outer three feathers pairs with progressively larger pale dull rufous terminal spots; throat and malar area dull brownish with narrow whitish streaks or

spots; underparts dull brown, upper breast with short, fine pale shaft streaks, lower breast and belly similar but streaks elongated and less distinct, vanishing on lower belly, undertail-coverts plain; iris dark brown; bill blackish to dark brownish; tarsus and toes dark greyish-brown. Differs from *C. nigrofumosus* in somewhat paler coloration, lack of white supercilium and throat. Sexes alike. Juvenile not described. VOICE. Song a long, loud trill; call described as abrupt "chec".

**Habitat.** Coastal rocky beaches; mainly in intertidal areas. One of the very few truly marine species in the Passeriformes.

**Food and Feeding.** Invertebrates; molluscs, crabs and isopods recorded in diet. Forages solitarily or in pairs. Gleans items from rocks and sand; often follows retreating waves.

**Breeding.** Presumably monogamous. Nest placed in crevice in coastal rocks; nest is cup of woven plant matter, mainly filamentous algae (e.g. *Chaetomorpha*, *Cladophora*, *Bryopsis*) and some feathers. No further information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Peru-Chile Pacific Slope EBA. Uncommon to fairly common within limited geographical range. Occurs in Paracas National Park and Pisco. Along with *C. nigrofumosus*, this is probably the most maritime of all passeriform species in terms of feeding habitats; nesting habitat, however, is unknown and requires investigation. Within range occupied by this species, coastal habitat is generally insulated from most types of human disturbance.

**Bibliography.** Cory & Hellmayr (1925), Koeppke (1954, 1961a, 1970), Parker *et al.* (1982), Paynter (1971), Remsen (2003a), Ridgely & Tudor (1994), Short & Morony (1969), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tovar (1968), Vuilleumier (1980a).

## 32. Seaside Cinclodes

### *Cinclodes nigrofumosus*

**French:** Cinclode du ressac

**Spanish:** Remolinerá Costera Chilena

**German:** Südlicher Felsuferwippler

**Other common names:** Chilean Seaside/d'Orbigny's Cinclodes

**Taxonomy.** *Uppucerthia nigro-fumosa* d'Orbigny and Lafresnaye, 1838, Cobja, "Bolivia" (= northern Chile).

Forms a superspecies with *C. taczanowskii* and may be conspecific; no indication that difference between the two is any greater than that found among races of e.g. *C. fuscus*. Monotypic.

**Distribution.** Coast of N & C Chile from Arica S to Valdivia, including I de los Pájaros and Mocha I.

**Descriptive notes.** 21-22 cm; 63-67 g. Large, very dark cinclodes with relatively short, straight bill. Has whitish supercilium, blackish lores and auriculars; crown and upperparts blackish-brown, wing-coverts with slightly less dark edgings and tips; remiges blackish with light rufous and whitish edgings at bases (dull wingband); tail rounded, blackish, outer three feathers pairs with progressively larger pale rufous terminal spots; throat and malar area to lower neck side white, underparts dark grey, upper breast with white spots, central breast to belly and flanks with white shaft streaks; iris brown to dark brown; bill blackish, lower

mandible sometimes with grey base; tarsus and toes brownish-grey to blackish. Differs from *C. taczanowskii* in darker appearance, contrasting white supercilium and throat. Sexes alike. Juvenile not described. VOICE. Song a long, loud trill.

**Habitat.** Coastal rocky beaches, mainly in intertidal areas. One of the very few truly marine species in the Passeriformes.

**Food and Feeding.** Invertebrates, including worms, crabs, molluscs, sea urchins (Echinoidea), gasteropods; also small fish. Forages singly or in pairs; occasionally associates with shorebird (Charadriiformes) flocks. Gleans and pecks invertebrates from intertidal rocks and beach debris; takes small fish stranded in tidal pools. Is apparently responsible for maintaining polymorphism in shell colour of the limpet *Scurria variabilis*, a major prey item, by removing contrasting individuals from accessible rocks.

**Breeding.** Season apparently during austral spring-summer; eggs in Sept. Presumably monogamous. Nest in hole or crevice in rocks in rocky coastal promontory; sometimes at end of tunnel excavated in bluff overlooking beach. Clutch 3-4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to fairly common within limited geographical range. In terms of feeding habitats, this species and *C. taczanowskii* are probably the most maritime of all passeriforms. Coastal habitat within its range appears to be generally well insulated from most types of anthropogenic disturbance.

**Bibliography.** Anon. (2003e), Araya & Chester (1993), Barros (1964), Cory & Hellmayr (1925), Hockey *et al.* (1987), Johnson (1967), Koepeke (1970), Marin (2003), Parker *et al.* (1982), Paynter (1971), Ridgely & Tudor (1994), Short & Morony (1969), Stotz *et al.* (1996), Vuilleumier (1980a).

### 33. Blackish Cinclodes

#### *Cinclodes antarcticus*

**French:** Cinclode fuligineux **German:** Rußbrauner-Uferwipper **Spanish:** Remolinera Negra  
**Other common names:** Tussock-bird; Falkland Islands Cinclodes (*antarcticus*)

**Taxonomy.** *Certhia antarctica* Garnot, 1826, Falkland Islands.

Close relationship to the superspecies formed by *C. taczanowskii* and *C. nigrofumosus* or to *C. patagonicus* suggested by plumage and ecological similarities; alternatively, considered by some to represent a distinct lineage within the genus on basis of general morphology. Two subspecies recognized.

**Subspecies and Distribution.**

*C. a. maculirostris* Dabbene, 1917 - extreme S South America, on Dawson I, Brecknock Peninsula (SW Tierra del Fuego), Navarino I, Cape Horn Archipelago and Staten I.

*C. a. antarcticus* (Garnot, 1826) - Falkland Is.

ee-ee-ee. Call "chip".

**Habitat.** Coastal rocky beaches, especially in vicinity of colonies of marine mammals and seabirds. In Falkland Is also extends inland in tussock grass (*Poa flabellata*) and around human habitations, occurring from sea-level to 100 m.

**Food and Feeding.** Mostly arthropods and marine invertebrates, including amphipods, isopods, Diptera and their larvae, and Orthoptera (Rhaphidophoridae). More omnivorous in Falkland Is, where recorded as eating cracked eggs of penguins (Spheniscidae) and cormorants (*Phalacrocorax*), also fish scraps and other food regurgitated by penguins. Forages singly or in pairs. Gleans food items from beaches, especially from kelp debris, in which it pecks holes and then pulls invertebrates through; also gleans invertebrates from seabird nests and excrement, and around beached marine mammals; leaps upwards to capture flies from air. Forages on floating kelp beds in Falklands, where also closely follows humans walking on beaches and chases invertebrates disturbed by them.

**Breeding.** Season during austral spring-summer; eggs recorded in Oct-Jan and nestlings in Nov-Jan in Falkland Is; single-brooded. Monogamous. Wing-flapping song display typical of genus. Following data all from Falklands. Nest at end of tunnel excavated in bank overlooking beach, or in hole or crevice in coastal rocks or boulders, occasionally in old building, or in hole in log or building, in burrow of Common Diving-petrel (*Pelecanoides urinatrix*), or in nook under or in building; nest-chamber lined with dried grasses, root fibres and some feathers, with material added even during nestling period. Clutch 2-3 eggs; incubation period c. 16 days; both parents feed nestlings, nest sanitation minimal, nestling period 25 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Southern Patagonia EBA. Uncommon to locally common. Occurs in Kidney Island Reserve, in Falkland Is. Was almost certainly more widespread formerly, but is now largely confined to islands free of introduced mammalian predators; this species' renowned tameness evidently makes it exceptionally vulnerable to terrestrial predators, particularly cats and rats (*Rattus*).

**Bibliography.** Anon. (1995), Araya & Chester (1993), Canevari *et al.* (1991), Cawkill & Hamilton (1961), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Humphrey *et al.* (1970), Johnson (1967), Mazar Barnett & Peaman (2001), Narosky *et al.* (1983), Olrog (1963a), de la Peña (1988), Pettingill (1973), Reynolds (1934, 1935), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1993b), Zotta (1938).

### 34. White-winged Cinclodes

#### *Cinclodes atacamensis*

**French:** Cinclode à ailes blanches **Spanish:** Remolinera Castaña  
**German:** Schwarzschwanz-Uferwipper

**Taxonomy.** *Upuarthia* [sic] *atacamensis* R. A. Philippi [Krumwiede], 1857, San Pedro de Atacama, Antofagasta, Chile. Two subspecies recognized.

**Subspecies and Distribution.**

*C. a. atacamensis* (R. A. Philippi [Krumwiede], 1857) - Andes from C Peru (Ancash, Huánuco, Pasco) S to C Chile (S locally to Santiago) and through Andes of Bolivia to NW Argentina (S to Mendoza).

*C. a. schocolatinus* Reichenow, 1920 - WC Argentina (Córdoba, San Luis).

**Descriptive notes.** 19-20 cm; 45-56 g. Fairly large, contrastingly marked cinclodes with long, decurved bill. Has whitish supercilium, brownish-grey loreal area, greyish-brown auriculars with reddish tones; crown greyish-brown, upperparts rich reddish-brown; dark reddish-brown wing-coverts, white bend of wing, blackish remiges with white bases (conspicuous white wingband); tail slightly rounded, central rectrices dark fuscous brown, paler along shaft, rest blackish-brown with white terminal spots becoming progressively larger towards outer feathers; throat and malar area whitish with some faint darker flecking (especially at side), breast and sides buffy greyish, blending to brownish-grey belly, faint pale shaft streaks and flecks along upper breast becoming elongated and much less conspicuous posteriorly, flanks rich brown, undertail-coverts mottled brown and greyish-white; iris dark brown; bill blackish to dark horn; tarsus and toes dusky brown. Sexes alike. Juvenile has pale-edged lower back feathers, less distinct breast markings. Race *schocolatinus* is darker brown above, greyer below, sides and flanks dark brown. **VOICE.** Song a trill; call a loud, whistled "wheel".

**Habitat.** *Puna* grassland and rocky or shrubby slopes, mostly at 2800-4500 m, locally down to 2200 m; almost always at edge of clear, flowing streams and trickles.

**Food and Feeding.** Reported dietary items are Coleoptera (Elmidae), Lepidoptera larvae, spiders, and snails (*Littoridina*). Solitary or in pairs. Gleans invertebrates from ground and mud, usually at edge of water.

**Breeding.** Season apparently during austral spring-summer; eggs in Nov and nestlings in Nov-Dec in Chile and Argentina; nestlings in Oct in S Peru; fledglings in Nov-Dec. Presumably monogamous. Nest a pad c. 8-10 cm wide and c. 2 cm deep of dry grasses and lined with hair, in chamber c. 11 cm in diameter placed at end of tunnel c. 1 m long excavated in bank, or in crevice in rocks or man-made structure. Clutch 2 eggs.

**Movements.** Mostly resident; some post-breeding downslope movement by race *schocolatinus* and other populations in extreme S of range. One anomalous record from coastal SW Peru, presumably involving vagrant.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Has comparatively large geographical range. Nature of habitat occupied by this species and its altitudinal range render it relatively insulated against human disturbance other than overgrazing.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Fjeldsá & Krabbe (1990), Fjeldsá & Majier (1996), Hughes (1980), Johnson (1967), Koepeke (1954, 1970), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Morrison (1939), Narosky *et al.* (1983), Nores & Yzurieta (1981), Nores *et al.* (1983), Olrog (1963a), Parker *et al.* (1982), Partridge (1953), Peña (1961), de la Peña (1983b, 1987, 1988), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Salvador (1990), Salvador & Narosky (1984), Short & Morony (1969), Stotz *et al.* (1996), Walker (2001), Zimmer (1930), Zotta (1940).

### 35. White-bellied Cinclodes

#### *Cinclodes palliatus*

**French:** Cinclode à ventre blanc **Spanish:** Remolinera Ventriblanca  
**German:** Weißbauch-Uferwipper

**Taxonomy.** *Cillurus palliatus* Tschudi, 1844, Montaña de Vitoc, near Hacienda Pachapata, Junín, Peru. Suggested by some as being most closely related to *C. atacamensis* on basis of plumage similarities. Monotypic.

**Distribution.** High Andes of C Peru (Junín, Lima, Huancavelica).

**Descriptive notes.** 23-24 cm; 99-109 g. Very large cinclodes with long bill and gleaming white underparts unlike any other furnariid. Has blackish loreal area, greyish-brown auriculars, blending to white in malar area; crown greyish, blending to rich brown on back, rump and uppertail-coverts; dark brownish wing-coverts with rich brown edging, blackish remiges with white at base (conspicuous white wingband); rounded tail blackish, narrow whitish tips on three outer pairs of rectrices; underparts pure white; iris dark brown; bill black; tarsus and toes black. Sexes alike. Juvenile undescribed; immature has chestnut auriculars, paler and browner crown. **VOICE.** Song described as a long trill that lasts 7-8 seconds; call a loud "chee" or "chipe" with rocky.

**Habitat.** Bogs with short grass and *Distichia* cushion-plants or adjacent *puna* grassland, with rocky slopes and often glaciers nearby; 4400-5000 m.

**Food and Feeding.** Mainly invertebrates, with "worms" as recorded items; also a small frog taken. Solitary or in pairs. Gleans invertebrates from ground, low vegetation, or water's edge.

**Breeding.** First nest reportedly found in early Nov 2002, made from plant material and feathers, placed among rocks beside new road; two chicks fluttering around foot of nest in mid-Dec, seen together with parents in early Jan 2003, when fed by parents with some insects obtained near nest. No further information available at present.

**Movements.** Presumably resident.

**Status and Conservation.** **VULNERABLE.** Rare and very local, with small geographical range. Recent records from just two sites c. 15 km apart in Cordillera de Huayhuash, on Junín-Lima border; no records since 1978 from other areas where known to occur formerly. Has been recorded in Junín National Reserve. No firm data on population size, trends, or specific threats. In ongoing study, begun in Feb 2000, 29 individuals located in various areas of the central mountain range and in surrounding area of the Huayhuash and Tielio snow-capped mountains, located between provinces of Lima and Junín, with further study planned to take place in Huancavelica in 2003; final results of these surveys and fieldwork should enable an estimate of the species' total population to be made. Although its general habitat is relatively free of anthropogenic disturbance, it apparently has highly specific micro-habitat requirements.

PLATE 14

# Genus *FURNARIUS* Vieillot, 1816

## 36. Pale-legged Hornero

### *Furnarius leucopus*

**French:** Fournier variable **German:** Blaufußtöpfer **Spanish:** Hornero Paticlaro  
**Other common names:** Caribbean Hornero (*endoecus*, *longirostris*); Pacific Hornero (*cinnamomeus*); Tricolour(ed) Hornero (*tricolor*)

**Taxonomy.** *Furnarius leucopus* Swainson, 1838, Guyana. Has been treated as conspecific with *C. torridus*, but the two occur sympatrically in NE Peru. Several races possibly represent separate species, but their songs all sound superficially very similar, and quantitative analysis is needed before determining potential splits. In particular, *cinnamomeus*, with which described form *pallidus* (La Libertad, in Peru) is synonymized, perhaps worthy of full species rank, while *longirostris* (with *endoecus*) may be part of that possible species or itself a distinct species; also, *tricolor* has sometimes been treated as a separate species. Otherwise, race *araguaiae*, described from just a few specimens from few localities, possibly represents only intergradation between *tricolor* and *assimilis*; taxonomic status tentatively maintained pending further analysis. Proposed race *exilis* (N Colombia), purportedly more richly coloured than others in Colombia, considered not diagnosable. Seven subspecies tentatively recognized.

#### Subspecies and Distribution.

*F. l. longirostris* Pelzel, 1856 - N Colombia (Córdoba E to lower Magdalena Valley) and NW Venezuela (NW Zulia E to W Falcón, NW Lara and Carabobo).  
*F. l. endoecus* Cory, 1919 - N Colombia (lower and middle Magdalena Valley) and W Venezuela (S Zulia).  
*F. l. leucopus* Swainson, 1838 - N Brazil (R Negro, R Branco) and SW Guyana.  
*F. l. cinnamomeus* (Lesson, 1844) - W Ecuador (S from W Esmeraldas) and NW Peru (S to N Ancash).  
*F. l. tricolor* Giebel, 1868 - E Peru (Amazonas S to Puno) and W Brazil (E to W Pará, S to N Mato Grosso) S to C Bolivia (Santa Cruz).  
*F. l. araguaiae* Pinto & Camargo, 1952 - SC Brazil (R Araguaia and R das Mortes in E Mato Grosso, possibly also W Goiás).  
*F. l. assimilis* Cabanis & Heine, 1859 - E & S Brazil (Maranhão E to Pernambuco, S to Bahia and S Mato Grosso) and extreme SE Bolivia (SE Santa Cruz).

**Descriptive notes.** 17-18 cm; 39-59 g. Large, richly coloured ovenbird with fairly long and nearly straight bill; strong but mostly concealed dark marks on undertail-coverts. Nominate race has conspicuous whitish supercilium from forehead back to rear nape, brownish-grey auriculars, tawny-rufous malar area; crown rather dark dull rufescent brown, back, rump and uppertail-coverts bright orange-rufous; chestnut wing-coverts, tawny at bend of wing, blackish remiges with conspicuous broad chestnut wingband; short tail broad, slightly rounded, chestnut; throat white, blending to tawny-ochraceous breast,

and to paler flanks and nearly whitish belly; undertail-coverts whitish, with mostly concealed dark brown bases; iris reddish-brown; upper mandible dusky horn at base, paler culmen and towards tip, lower mandible paler; tarsus and toes pinkish. Sexes alike. Juvenile is similar to adult. Race *tricolor* has more ochraceous back, paler than wings and tail, greyer crown; *assimilis* is like last, but has lighter, more ochraceous rump, wings and tail, paler wingband continuing to inner web of outer primary; *araguaiae* is intermediate between previous two, dark-crowned, differing from last in having darker bill, brighter back (brighter than wings and tail), cinnamon patch in remiges smaller; *cinnamomeus* is larger, has pale crown, yellow to whitish iris, longer, more curved bill with mostly dark upper mandible, narrow brownish-grey eyeline contrasting with tawny auriculars, paler underparts, large ochraceous spot on inner web of outer primary; *longirostris* is like last, but more richly coloured below, has paler, greyer crown, narrower wingband, dark iris, lacks trace of ochraceous spot in outer primary; *endoecus* differs from last in darker, less ochraceous upperparts. **Voice.** A series of loud, explosive, piercing, staccato notes, decelerates and descends in pitch, lasts 6-8 seconds, often given in duet; *longirostris* song described as shorter rattle, c. 4 seconds, accelerating and then slowing, on even pitch or falling slightly at end; transliterations of songs of *tricolor* and *cinnamomeus* superficially very similar to others. Call a loud, rich "chet" or "kyeek", or descending "cheep".

**Habitat.** Second-growth scrub, pastures/agricultural land; a variety of semi-open habitats with bare soil: river-edge forest and woodland, gallery forest, second-growth woodland edge, desert river valleys; also fields (pasture, agricultural land), and in towns. Often (but not always) near water. Mainly from near sea-level to 800 m; to 2300 m, locally 2700 m, in Ecuador and NW Peru (*cinnamomeus*).

**Food and Feeding.** Arthropods and other invertebrates; recorded items are termites (Isoptera), ants, Coleoptera (Curculionidae), lepidopteran larvae, and small crabs. Solitary or in pairs. Gleans food items from ground, occasionally flaking leaves; walks on ground.

**Breeding.** Eggs in May and Sept in N Colombia; eggs and nestlings in Nov in E Peru. Presumably monogamous. Nest an "adobe oven" 18-20 cm high, weight 2 kg, made of mud, and placed on tree branch (often, possibly always, over water in Amazonia), nest-chamber lined with plant fibres, mostly leaf petioles; reported also as using old nest of *F. rufus*, *Phacellodomus rufifrons* or *Pseudoseiura lophotes* in E Brazil. Clutch 2 eggs. Abandoned nest of present species frequently taken over by Pacific Parrotlets (*Forpus coelestis*) in NW Peru.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to very common. Occurs in several protected areas, including Tayrona National Park, in Colombia, Rio Palenque Science Centre,

in Ecuador, Tambopata-Candamo Reserved Zone, in Peru, and Pantanal National Park, in Brazil. Benefits from moderate anthropogenic habitat alteration, and has extended its range into deforested areas.

**Bibliography.** Angehr & Aucca (1997), Boesman (1998), Chapman (1926), Cook (1996), Cory & Hellmayr (1925), Dyrce (1987), Ejlsdál & Krabbe (1990), Foster *et al.* (1994), Haffer (1975), Hilty (2003a), Hilty & Brown (1986), Koepcke (1961a, 1972), Naumburg (1930), Parker & Bailey (1991), Parker, Parker & Plenge (1982), Parker, Schulenberg, Graves & Braun (1985), Parker, Schulenberg, Kessler & Wust (1995), Parrini *et al.* (1999), Remsen (2003a), Remsen & Parker (1983), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgely *et al.* (1998), Robinson (1997), Robinson & Terborgh (1997), Rodner *et al.* (2000), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Taczanowski (1884), Terborgh *et al.* (1984), Todd (1948b), Todd & Carriker (1922b), Traylor (1958), Vaurie (1973), Wiedenfeld *et al.* (1985), Willis (1992b), Willis & Oniki (1990), Zimmer (1936a).

## 37. Pale-billed Hornero

### *Furnarius torridus*

**French:** Fournier à bec clair **German:** Brauner Töpfer **Spanish:** Hornero Castaño  
**Other common names:** Bay Hornero

**Taxonomy.** *Furnarius torridus* P. L. Sclater and Salvin, 1866, Rio Ucayali, Peru.

Has been treated as conspecific with *C. leucopus*, or formerly as a dark morph of that species, but the two occur sympatrically in NE Peru. Monotypic.

**Distribution.** Extreme NE Ecuador (Lagartococha), NE Peru and extreme W Brazil, mainly along R Amazon, R Napo and R Ucayali.

**Descriptive notes.** 15-17 cm; 48-57 g. Adult has dull buff supercilium, dark brownish auriculars with some paler shaft streaks, rich brownish loreal and malar areas; crown dull dark brown, upperparts rich dark chestnut; rich dark chestnut wing-coverts and secondaries, dark fuscous primaries, rufous wingband; short tail broad, slightly rounded, deep chestnut; throat white; breast and flanks rich rufescent brown, belly buff to whitish in centre, undertail-coverts cinnamon-buff or pale rufescent brown with mostly or wholly concealed blackish bases; iris brown to reddish-brown; upper mandible whitish to light horn, base blackish, lower

mandible pale pinkish-horn; tarsus and toes pinkish. Differs from similar *F. leucopus* in darker coloration throughout. Sexes alike. Juvenile known from single specimen, resembles adult but has dark flecking on breast. **Voice.** Similar to that of *F. leucopus*, but series of notes is noticeably faster. Call is a loud, harsh "cheek!".

**Habitat.** Flooded tropical evergreen forest, river-edge forest; especially old or middle-aged river islands, from *Cecropia*-dominated woodland to older successional stages; 150-300 m.

**Food and Feeding.** Arthropods and presumably other invertebrates. Solitary or in pairs. Forages while walking. Food items gleaned from ground and shoreline mud.

**Breeding.** No modern information; 19th-century report of stick nest placed in riverbank, and clutch of 4 eggs, requires corroboration.

**Movements.** Probably mainly resident, but ephemeral nature of its river-island habitat must force at least local seasonal movements. Possibly only an occasional visitor or wanderer to NE Ecuador.

**Status and Conservation.** Not globally threatened. Uncommon throughout most of range; recorded regularly at ExplorNapo Lodge, in Peru, where a sizeable area of habitat remains in good condition. Very poorly known species.

**Bibliography.** Cory & Hellmayr (1925), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgely *et al.* (1998), Rosenberg, G.H. (1990), Sclater & Salvin (1873), Stotz *et al.* (1996), Vaurie (1973), Zimmer (1936a).

## 38. Lesser Hornero

### *Furnarius minor*

**French:** Petit Fournier **German:** Kleiner Töpfer **Spanish:** Hornero Chico

**Taxonomy.** *Furnarius Opetiorhynchus minor* Pelzel, 1858, Rio Madeira, below the mouth of the Rio Mahissy (= Igarapé Maici), Rondônia, Brazil.

A close relationship to *F. leucopus* is suggested by both plumage pattern and geographical distribution. Monotypic.

**Distribution.** R Amazon and lower reaches of major tributaries from SE Colombia, E Ecuador (R Napo) and NE Peru (S to lower R Huallaga) E to NC Brazil (mouth of R Tapajós); extends well up R Madeira, reaching at least mouth of R Ji-Paraná (Rondônia).

**Descriptive notes.** 12-13 cm; 23-29 g. Very small ovenbird with fairly long and nearly straight bill. Adult has conspicuous whitish supercilium from forehead back to rear nape; auriculars and loreal area grizzled greyish-brown, vague darker postocular line; crown dull brownish-grey, back, rump and uppertail-coverts dull rufous; wing-coverts and secondaries mostly rufous, bend of wing whitish, primaries dark fuscous with some rufous showing (rufous wingband); short tail nearly square to slightly rounded, rufous, slightly darker than back; throat white; breast dull tawny-buff, becoming paler on belly and below, lower flanks

slightly brighter, tawny-ochraceous; undertail-coverts with mostly or wholly concealed dark bases; iris dark brown; upper mandible dark brownish-horn, lower mandible pale horn with dark tip of

On following pages: 39. Rufous Hornero (*Furnarius rufus*); 40. Crested Hornero (*Furnarius cristatus*); 41. Wing-banded Hornero (*Furnarius figulus*); 42. Curve-billed Reedhaunter (*Limnornis curvirostris*); 43. Straight-billed Reedhaunter (*Limnornis rectirostris*); 44. Wren-like Rushbird (*Phleocryptes melanops*); 45. Thorn-tailed Rayadito (*Aphrastura spinicauda*); 46. Masafuera Rayadito (*Aphrastura masafuerae*).

varying extent; tarsus and toes grey to horn-coloured. Sexes alike. Juvenile undescribed. Voice. A fast, harsh series of staccato "kee" notes that decelerate and descend in pitch, ending in trill; often in duet. Call described as sharp "krik".

**Habitat.** River-island scrub; early-successional scrub, from *Tessaria*-dominated or *Alchornea*-dominated stage to *Cecropia* woodland, along large white-water rivers, primarily on young river islands; in a study in Peru, understorey of tall *Cecropia* forest and *Tessaria* scrub were the two most heavily used habitats. From 50 m to 200 m.

**Food and Feeding.** Arthropods and probably other invertebrates. Solitary or in pairs. Forages while walking. Food obtained by gleaning from ground, shoreline mud, and low branches, often in or near dense cover.

**Breeding.** Nest a mud oven placed on horizontal branch, nest-chamber lined with grasses and hair. Clutch 4 eggs. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. Global population very small owing to patchy distribution of habitat and linear geographical range. Suitability of habitat depends on seasonal flooding along major rivers; thus, potentially vulnerable to human alteration of flooding cycle, as well as habitat destruction, which includes seasonal agriculture along rivers.

**Bibliography.** Cohn-Haft (2003a), Cory & Hellmayr (1925), Hilty & Brown (1986), Parker *et al.* (1982), Pearman (1993b), Pinto (1978), Remsen (2003a), Remsen & Parker (1983), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg, G.I. (1990), Selater & Salvin (1873), Sick (1993, 1997), Stotz *et al.* (1996), Tallman & Tallman (1977).

## 39. Rufous Hornero

### *Furnarius rufus*

**French:** Fournier roux **German:** Rosttöpfer **Spanish:** Hornero Común  
**Other common names:** Red Hornero/Ovenbird

**Taxonomy.** *Merops rufus* J. F. Gmelin, 1788, Buenos Aires, Argentina.

Plumage pattern and biogeography suggest that most likely sister-species is *F. cristatus*. Race *albugularis* previously known as *hadius*, but that taxon was described within genus *Turdus*, in which the name was preoccupied. Significant variation in body size follows Bergmann's Rule, with largest birds farthest from equator. Relative distributions in Argentina of *paraguayae* and *commerstoni* require further study. Proposed race *schuhmacheri* (S Bolivia) does not appear to be diagnosable; description believed to have been based on worn specimens. Four subspecies recognized.

#### Subspecies and Distribution.

*F. r. commerstoni* Pelzeln, 1868 - C & E Bolivia (La Paz and Beni S to Tarija and Santa Cruz), SW Brazil (Mato Grosso) and NW Argentina (N Salta, SE Jujuy).

*F. r. paraguayae* Cherrie & Reichenberger, 1921 - Paraguay and N Argentina (Formosa S to La Rioja, N Santiago del Estero and N Santa Fe).

*F. r. albugularis* (Spix, 1824) - E & SE Brazil (S Ceará, Alagoas, Bahia, and Goiás S to São Paulo and Rio de Janeiro).

*F. r. rufus* (J. F. Gmelin, 1788) - SE Brazil (Paraná S to Rio Grande do Sul), Uruguay and C & E Argentina (from S Santiago del Estero E to Corrientes, S to Neuquén and N Rio Negro).

**Descriptive notes.** 16-23 cm; 31-65 g. Large ovenbird with medium-length, nearly straight bill. Has poorly defined light rufous supercilium, loreal area and malar area, slightly darker auriculars; forehead rufous-brown, blending into dull brown crown; more rufescent hindneck; back and rump rufescent brown with some paler edgings, uppertail-coverts rufous; wing-coverts and secondaries rufescent brown, bend of wing pale buff, primaries dull brownish with light rufous wingband; short tail slightly rounded to nearly square, mostly dark rufous; throat whitish, blending to pale vinaceous tawny on breast.

to paler buff belly; flanks darker, more tawny, undertail-coverts buffy whitish with concealed dull brownish bases; iris rufous-brown to cinnamon; upper mandible fuscous to greyish or dark brownish-horn, lower mandible pale horn to pinkish with dark tip; tarsus and toes greyish, brownish or blackish. Sexes alike. Juvenile is paler below. Race *albugularis* is smaller, with darker, greyer crown, more conspicuous broader reddish collar, much more ochraceous below; *commerstoni* is like previous but collar even broader, back redder, belly paler, less ochraceous; *paraguayae* differs from last in more rufescent forehead and nape, has less greyish underparts. Voice. Song a long, rhythmic, raucous burst of loud, sharp "kweep!" notes, trails off towards end but often with some slower, emphatic, complaining terminal notes; often in duet. Calls include sharp "jeet!", "jeah" or "krip", often in series.

**Habitat.** Second-growth scrub, pastures and agricultural land; a variety of open habitats, particularly disturbed areas with bare soil; second-growth scrub, pasture and agricultural land, also urban parks and gardens. Especially common near human habitations. Mostly in lowlands; ranges into mountains in some dry or agricultural valleys, to 3500 m.

**Food and Feeding.** Arthropods and other invertebrates; also some seeds. Reported dietary items are Coleoptera (of families Curculionidae, Chrysomelidae, Elateridae, Carabidae, Cassidae, Tenebrionidae, Aphodiidae, Histeridae, Scarabaeidae), ants (e.g. *Pheidole*, *Crematogaster*, *Acromyrmex*), termites (Isoptera), lepidopteran larvae, grasshoppers (Acrididae), Hemiptera, worms (Annelida), spiders, and snails (*Planorbis*); ants seem particularly well represented in stomach samples. Nestlings fed with crickets (Gryllidae), mole-crickets (*Scapteriscus*), coleopteran and lepidopteran larvae, Annelida, spiders. Solitary or in pairs; occasionally, or perhaps locally, associates with foraging groups of Chalk-browed Mockingbirds (*Mimus saturninus*). Forages while walking. Gleans invertebrates and some seeds from bare ground and leaf litter, very rarely from trunks and branches.

**Breeding.** Season largely during austral spring-summer; eggs in Sept-Dec and nestlings in Oct to mid-Jan in Argentina; nestlings in Oct-Jan in S Brazil; frequently double-brooded. Monogamous; paired throughout year, often lifelong pair-bond. Nest a large globular "adobe oven" 20-30 cm in diameter, 20-25 cm tall, walls typically 3-5 cm thick, made of clay, mud, some dung, and straw, weight c. 3-5 kg, orientation of entrance variable, usually facing away from prevailing wind (in some studies), occasionally two openings or with entrance at top, interior wall separating narrower vestibule from larger nest-chamber, floor of latter with bits of grasses and stems; placed up to 8 m above ground in open location on tree branch, fence post, telephone

pole, rooftop or almost any structure, occasionally on bare ground, rock, or on top of as many as three older nests, or even in or on skull of dead mammal or large tin can; building activity occurs throughout year, entire nest typically completed within 2-3 months but can be built in 15 days, sometimes more than one nest built but only one used; territory probably defended all year, size 0.25-1 ha. Clutch 2-4 eggs, rarely 5 (mean 3-5 in C Argentina), laid at 1-day intervals; incubation by both sexes, period 14-18 days; both also brood and feed chicks, nestling period c. 23-26 days; juveniles remain in parental territory for 4-9 months, occasionally attempt to help with nest-building but attacked by parents when they do. Regularly parasitized by Shiny Cowbird (*Molothrus bonariensis*), eggs of which sometimes ejected. High nesting success with 2-5 young fledged per clutch in one detailed study, but only 1-3 per clutch in another study; main factor causing reduced success was starvation of nestlings, probably affecting especially the last-hatched in broods of 4; in another study abnormally high temperatures were apparently major cause of mortality. Annual adult survival rate 71%.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to abundant throughout range in suitable habitats, i.e. human-disturbed areas. Benefits from moderate anthropogenic habitat alteration; has expanded its distribution during 20th century, primarily as a result of deforestation. Old nests of this furnariid are used extensively by other bird species, both for nesting and as roost-sites.

**Bibliography.** Basterreix (1923a, 1923b), Belton (1984), Burger (1976, 1979), Burghi (1937), Canevari *et al.* (1991), Contreras (1979e), Cordero (1931), Cory & Hellmayr (1925), Cuello (1985), Daguerre (1921), Davis (1993), Doello-Jurado (1919), Drabble (1953), Esteban (1951b), Fiora (1933), Fjeldså & Krabbe (1990), Fjeldså & Møller (1996), Fraga (1979, 1980), Fraga & Narosky (1985), Friedmann (1927), Gavio (1938), Gazari (1967), Harper (1932), Hayes (1995), Hermann & Meise (1966), Kay (1941), Kirwan & Mazar Barnett (2001), Kratter *et al.* (1993), MacDonald (1953), Madroño, Robbins & Zyskowski (1997), Mason (1985), Melo-Júnior *et al.* (2001), Narosky *et al.* (1983), Navas & Bó (1987), Nores & Yzurieta (1982), Parker & Goerck (1997), Parker, Gentry *et al.* (1993), Parrini *et al.* (1999), Partridge (1953), de la Peña (1987, 1988), Pereyra (1939, 1940), Peris (1990), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Ríos-Paredi (1973), Salvador (1988), Schubart *et al.* (1965), Serié (1919), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Tálce & Mosera (1964), Teixeira *et al.* (1987), Tremoleras (1929), Vaz-Ferreira & Palerm (1973), Vaz-Ferreira, Palerm *et al.* (1993), Vaz-Ferreira, Stagi & Bianco (1992), Vaz-Ferreira, Stagi, Loinaz & Bianco (1998), Webster (1941), Wetmore (1926), Willis (1992b), Willis & Oniki (1990), Zotta (1936, 1940).

## 40. Crested Hornero

### *Furnarius cristatus*

**French:** Fournier huppé **German:** Haubentöpfer **Spanish:** Hornero Copetón

**Taxonomy.** *Furnarius cristatus* Burmeister, 1888, Sierra de Córdoba, Argentina.

Plumage pattern and biogeography suggest that the most likely sister-species is *F. rufus*. Monotypic.

**Distribution.** Extreme SE Bolivia (SE Chuquisaca, E Tarija) and W Paraguay S to C Argentina (S to S San Luis, N Córdoba, C Santa Fe, NW Entre Ríos).

**Descriptive notes.** 14-15 cm; 26-29 g. Small ovenbird with distinctive crest, bill shorter than that of congeners. Adult has inconspicuous pale supercilium, whitish loreal area, and dull brownish malar area and auriculars vaguely outlined with darker brown; forehead rufescent, contrasting with duller clay-brown crown with feathers elongated into crest; back and rump dull tawny-rufous, uppertail-coverts rufous; wing-coverts and remiges mostly dull tawny-brown, remiges with rufous edges, bend of wing whitish; tail slightly rounded to nearly square, central rectrices dull rufous, rest brighter rufous; throat whitish, blending to dull

tawny breast; belly and flanks more tawny, centre of belly nearly whitish, undertail-coverts tawny whitish with mostly or wholly concealed rufescent-brown bases; iris brownish-red; upper mandible blackish, lower mandible flesh-coloured, with darker tip; tarsus and toes grey. Sexes alike. Juvenile undescribed. Voice. Song an explosive staccato burst of loud, piercing whistled notes tailing off towards end, c. 4-5 seconds long, shriller than song of *F. rufus*; often in duet. Call "jwee-t-t-t-t-t-t-t-t".

**Habitat.** Arid lowland scrub; Chaco scrub and arid woodland, particularly around houses and clearings; to 1000 m.

**Food and Feeding.** Arthropods. Solitary or in pairs. Gleans items from ground.

**Breeding.** Breeds during austral spring and summer; eggs in Nov in Argentina. Presumably monogamous. Nest a hardened "adobe oven" c. 20 cm in diameter and c. 15 cm tall, similar to that of *F. rufus* but smaller, floor of nest-chamber with bits of grass, placed c. 2-5 m up on branch of bush or tree. Clutch 4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout range. Occurs in Chancani Natural Reserve, in Argentina. Benefits from modest anthropogenic habitat modification.

**Bibliography.** Anon. (2003d), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Esteban (1951b), Friedmann (1927), Hayes (1995), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Nellar (1993), Nores *et al.* (1983), Ochoa (1971), Olrog (1963a), de la Peña (1987, 1988, 1997), Remsen & Ridgely (1980), Remsen & Traylor (1983, 1989), Ridgely & Tudor (1994), Salvador (1990), Short (1975), Smyth (1928), Stotz *et al.* (1996).

## 41. Wing-banded Hornero

### *Furnarius figulus*

**French:** Fournier bridé **German:** Schwarzspitzentöpfer **Spanish:** Hornero Colibandeado  
**Other common names:** Band-tailed/Tail-banded/White-banded Hornero; Pileated Hornero (*pileatus*)

**Taxonomy.** *Turdus figulus* M. H. K. Lichtenstein, 1823, Bahia, Brazil.

The most aberrant member of the genus with respect to nest type and some plumage features. Distinctive race *pileatus* considered possibly a separate species by some authors. Two subspecies recognized.

**Subspecies and Distribution.**

*F. f. pileatus* P. L. Selater & Salvin, 1878 - EC Brazil from E Amazonas E to C Pará and NW Goiás (upper R Araguaia).  
*F. f. figulus* (M. H. K. Lichtenstein, 1823) - E Brazil (E from E Maranhão, S Bahia and N & E Minas Gerais).

**Descriptive notes.** 15-16 cm; 28 g. Small hornoro with fairly long, nearly straight bill. Nominate race has conspicuous whitish supercilium extending to nape side, dingy rufous loreal area, dark eyestripe, dull rufous auriculars, tawny-buff malar region; crown chestnut-rufous, back, rump and uppertail-coverts slightly paler; wing-coverts and secondaries rufous, bend of wing whitish, primaries fuscous with dark rufous wingband; tail nearly square, same colour as back, rectrices tipped brownish-black, mainly on inner webs; throat whitish, blending to dull pale tawny-brown below, centre of belly whitish, undertail-coverts almost white; iris brown; bill brownish; tarsus and toes brownish. Sexes alike. Juvenile undescribed. Race *pileatus* has much darker brown crown and auriculars, whiter supercilium, deeper rufous back, larger and more numerous tail spots. **Voice.** Song a series of 6-10 staccato "chik" notes, decelerating and descending in pitch; often duets. Calls include "chibit, chcp" and loud "kwee-eh".

**Habitat.** River-edge woodland and second-growth scrub, including in disturbed open areas, gardens, pastures and marsh edge; usually near water, especially rivers. From near sea-level to 600 m, locally to 900 m; recorded at 1250 m in Minas Gerais.

**Food and Feeding.** Invertebrates; one stomach contained 16 Coleoptera, 2 Hemiptera, and a snail (Hydrobiidae). Forages singly or in pairs. Walks on ground, where turns over leaves and branches; invertebrates gleaned from ground or mud.

**Breeding.** Eggs in Apr; fledglings in Mar. Presumably monogamous. Nest a shallow open cup made from grass and plant fibres, lined with feathers and hair, hidden in "cavity" in bases of palm leaves (e.g. *Orbignya*) or in bromeliads, occasionally in crevice in building; reports of this species making "oven" nests possibly erroneous. Clutch 2 eggs; incubation period reported as 20 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Global population probably very small owing to patchy distribution of habitat and linear geographical range. Occurs in Rio Doce and Pedra Talhada State Parks. Range has expanded during the last century.

**Bibliography.** Anon. (2003e), Cohn-Haft (2003a), Cory & Hellmayr (1925), Ferreira de Vasconcelos & Melo-Júnior (2001), Graves & Zusi (1990), Kirwan *et al.* (2001), Melo-Júnior *et al.* (2001), Parker & Goerck (1997), Parrini *et al.* (1999), Pinto (1978), Remsen & Parker (1983), Ridgely & Tudor (1994), Schubert *et al.* (1965), Sick (1993, 1997), Sneath (1935), Stotz *et al.* (1996), Studer & Viellard (1990), Willis (1992b), Zyskowski & Prum (1999).

## Genus *LIMNORNIS* Gould, 1839

### 42. Curve-billed Reedhaunter

*Limnornis curvirostris*

**French:** Synallaxe à bec courbe **Spanish:** Pajonalera Piquicurve  
**German:** Braunrücken-Riedschlüpfer  
**Other common names:** Curve-billed Reedrunner

**Taxonomy.** *Limnornis curvirostris* Gould, 1839, Maldonado, Uruguay.

No obvious close relatives; *Limnornis curvirostris* placed in present genus by some authors, whereas others do not consider the two to be closely related. Differs strongly from that species in tail structure, nest materials used, and greenish-blue egg colour (unusual within family). Monotypic.

**Distribution.** Extreme SE Brazil (coastal Rio Grande do Sul), S Uruguay and extreme E Argentina (Entre Ríos, E Buenos Aires).

**Descriptive notes.** 15-17 cm; 27-30 g. Rather plainly coloured, long-billed furnariid; remarkably similar to some Old World sylviid warblers of genus *Acrocephalus*. Has conspicuous whitish supercilium, poorly defined dark brown postocular line blending to brighter auriculars with some whitish shaft streaks; crown to uppertail-coverts rich brown, darkest on forehead, brightest and most rufescent on tail-coverts; wings and graduated tail rufescent brown; throat and malar area whitish, blending to slightly darker, more buffy breast, pale creamy buff below, richer buff on undertail-coverts and more cinnamon on

flanks; iris brown; upper mandible brown to blackish, lower mandible whitish mixed brownish; tarsus and toes greyish. Differs from *Limnornis rectirostris* in heavier build, shorter and clearly decurved bill, brown crown and upperparts. Sexes alike. Juvenile undescribed. **Voice.** A fast series of harsh notes that ascend and then descend in pitch, fading towards end; call a hollow "took".

**Habitat.** Freshwater marshes; extensive reedbeds in freshwater marshes and coastal lagoons, locally brackish; predominant vegetation often *Scirpus giganteus* and *Zizaniopsis bonariensis*. Sea-level to 100 m.

**Food and Feeding.** Arthropods; recorded items are ants, grasshoppers (Acrididae), and Coleoptera (including Chrysomelidae) and their larvae. Usually solitary. Gleans food items from marsh vegetation.

**Breeding.** Season presumably during austral spring-summer. Presumably monogamous. Nest a globular ball c. 22 cm in diameter, made from woven grasses, leaves and fibres, interior with bed of

soft plant material, side entrance protected by slight "awning", variously reported as attached to reeds or as supported by vegetation below. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Apparently uncommon; status poorly known. Occurs in Aparados da Serra National Park, in Brazil, and Costanera Sur, Ingeniero Otamendi, and Ribera Norte Reserves, in Argentina. Narrow habitat requirements appear to render it potentially vulnerable.

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Klimaitis & Moschione (1987), López *et al.* (1999), Mason (1985), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), de la Peña (1988, 1997), Pinto (1978), Ricci & Ricci (1984), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Willis (1992b), Zotta (1932, 1936), Zyskowski & Prum (1999).

## Genus *LIMNOCTITES* Hellmayr, 1925

### 43. Straight-billed Reedhaunter

*Limnornis rectirostris*

**French:** Synallaxe à bec droit **Spanish:** Pajonalera Piquirrecta  
**German:** Grauscheitel-Riedschlüpfer  
**Other common names:** Straight-billed Reedrunner

**Taxonomy.** *Limnornis rectirostris* Gould, 1839, Maldonado, Uruguay.

No obvious close relatives; placed by some authors in genus *Limnornis*, whereas others do not consider the two genera closely related. Differs strongly from that taxon in tail structure, nest materials used, and white egg colour. Monotypic.

**Distribution.** Extreme SE Brazil (Rio Grande do Sul), Uruguay and extreme E Argentina (Entre Ríos, N Buenos Aires).

**Descriptive notes.** 16-17 cm; 16-21 g. Has whitish supercilium, greyish face; dark grey crown, brownish-grey back and rump, rufous wings and tail; tail graduated, protruding bare shafts; throat whitish, breast and belly slightly duller, flanks and undertail-coverts tinged buff; iris light brown to orange-red; upper mandible dark horn to blackish, lower mandible pinkish-grey, whitish or yellowish-orange with dark tip; tarsus and toes dark greyish to yellowish-olive. Differs from rather similar *Limnornis curvirostris* in less heavy build, longer and barely decurved bill, grey crown and back. Sexes alike. Juvenile is more rufescent above,

more ochraceous below. **Voice.** High-pitched broken trill of "pee" or "ti" notes, all on same pitch, accelerating at end, variably 2-4 seconds long; call "chek" or "tzig".

**Habitat.** Freshwater marshes and other wet areas dominated by the spiny apiaceous herb "caraguatá" (*Eryngium*), and shrubs and short trees bordering these wet areas; locally also away from water in upland thickets of *Eryngium pandanifolium*. Up to 1100 m.

**Food and Feeding.** Arthropods; Coleoptera, Hemiptera and Hymenoptera recorded as taken. Usually solitary. Gleans food items from marsh vegetation.

**Breeding.** Season presumably during austral spring-summer; eggs in Nov and nestlings in Jan. Monogamous. Nest an oval-shaped ball c. 20 cm tall and 15 cm wide, made from leaves (especially of *Eryngium horridum* and *Scirpus*) and twigs, side entrance protected by slight "awning", placed c. 0.3-1 m above ground and supported below by marsh vegetation. Clutch 2-3 eggs; both sexes incubate.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Fairly common but very local. Fairly common in Aparados da Serra National Park, in Brazil; Ingeniero Otamendi Reserve, in Argentina, is a stronghold. Narrow habitat requirements render this species potentially vulnerable. Drainage of marshland a possible threat throughout range, and in areas with large human populations, such as province of Buenos Aires in Argentina, small wetlands are at risk from the dumping of large quantities of refuse, as well as water pollution. Extensive plantations of willows (*Salix*), eucalyptus (*Eucalyptus*) and pines (*Pinus*) also consume huge amounts of underground water, resulting in the drying-out of wetlands; this thought to be a major problem in E parts of Entre Ríos, in Argentina.

**Bibliography.** Babarskas & Fraga (1998), Belton (1984), Canevari *et al.* (1991), Carriquiry (1998), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Daguerre (1933), Escalante (1956), Fraga & Narosky (1985), Gerzenstein & Achaval (1967), López *et al.* (1999), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parker & Goerck (1997), de la Peña (1988, 1997), Pereyra (1938), Pinto (1978), Ricci & Ricci (1984), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Willis (1992b), Zorrilla (1963), Zyskowski & Prum (1999).

## Genus *PHLEOCRYPTES*

Cabanis & Heine, 1859

### 44. Wren-like Rushbird

*Phleocryptes melanops*

**French:** Synallaxe troglodyte **German:** Binsenschlüpfer **Spanish:** Junquero  
**Other common names:** Rushbird, Black-faced Spinetail

**Taxonomy.** *Sylvia melanops* Vieillot, 1817, Paraguay.

Affinities uncertain. Possible relationship to *Aphrastura* suggested by plumage features, but nest architecture considered by some to be more like that of similarly marsh-nesting *Limnoctites* and *Limnornis*; blue-green egg colour (unusual within family) more like latter's. Proposed race *juninensis* (from vicinity of L. Junin, in C. Peru), purportedly with brighter plumage, evidently not diagnosable. Four subspecies recognized.

**Subspecies and Distribution.**

*P. m. brunescens* J. T. Zimmer, 1935 - coastal W Peru (La Libertad S to Ica).

*P. m. schoenobaenus* Cabanis & Heine, 1859 - C & S Peru (L. Junin area in Andes of Junin, Altiplano region of Puno), W Bolivia (La Paz S to Oruro) and NW Argentina (Jujuy).

*P. m. loensis* R. A. Philippi [Baños] & Goodall, 1946 - coastal S Peru (Arequipa) and N Chile (Tarapacá).

*P. m. melanops* (Vieillot, 1817) - lowlands of SE Brazil (São Paulo S to Rio Grande do Sul), Argentina (Tucumán E to Misiones, S to Chubut) and Chile (Atacama S to Aisén), but N limits of breeding unclear; also to W Paraguay in non-breeding season.

**Descriptive notes.** 13-14 cm; 11-16 g. Small furnariid, remarkably similar in plumage to Marsh Wren (*Cistothorus palustris*). Male nominate race has prominent buff supercilium extending to hindcrown, loreal area grizzled with greyish, dark brown postocular band, auriculars mottled dark brown, rear of malar area buff; blackish crown with broad, blurry brown streaks and faint pale feather shafts, poorly defined buff-brown collar less streaked, blackish back with rich brown streaks and prominent whitish feather shafts; rich brown rump and uppertail-coverts, latter mixed with blackish; blackish wings, coverts with broad

chestnut tips forming wingbars, remiges with chestnut and rufous edgings (conspicuous broad chestnut wingband); tail graduated, central rectrices rich brown, rest blackish-brown with buffy to tawny tips and (on outer webs of outer rectrices) edges, inner two feather pairs with c. 4 mm of distal shafts bare; throat white, blending to buffy whitish on breast and belly, contrasting with dull brown sides and flanks; undertail-coverts mixed tawny-buff and white; iris brown to dark brown; bill blackish to dark horn, sometimes pale pinkish or greyish base of lower mandible; tarsus and toes greyish-horn. Female is slightly paler than male. Juvenile has crown feathers with rufous shafts, feathers of underparts with narrow dark edges. Race *schoenobaenus* is significantly larger and longer-billed, brighter above and whiter below than nominate; *brunescens* has paler, more heavily streaked crown, browner (less blackish) back, paler wingband, much paler and duller underparts; *loensis* is like previous, but wingband darker, more chestnut, and rump, sides and flanks darker. **VOICE.** A repeated mechanical ticking, repeated several times per second, sometimes for several minutes, often ending with trill like that of cicada (Cicadidae); Andean populations described as similar but with more strident tones. Calls include buzzy "zzt", nasal "ik" or "eh", and various squeaky notes.

**Habitat.** Freshwater marshes; fresh or brackish marshes and lake edges with aquatic vegetation, especially *Scirpus* rushes; sea-level to 4300 m.

**Food and Feeding.** Arthropods. Usually solitary. Gleans items from emergent or floating aquatic vegetation, also occasionally from water and adjacent mud.

**Breeding.** Breeds during austral spring-summer; eggs in Sept and Jan in Peru, Oct and Feb in S Brazil and Sept-Jan in Argentina; nestlings in Sept in Peruvian Andes and Oct-Feb in Argentina. Presumably monogamous. Nest a globular mass c. 12-18 cm tall and 9-12 cm broad, of woven water-soaked grasses and fibres cemented together with mud, which dries to form hard outer shell, lined with feathers and hairs, side entrance near top usually protected by slight "awning", attached with grass blades and cemented with mud to 3-7 reeds or *Solanum malacoxylon* stems 0.4-0.9 m (usually c. 0.8 m) above water. Clutch 2-4 eggs; incubation 16 days.

**Movements.** Mainly resident; some N migration by S populations during austral winter, but uncertain whether any parts of S range then abandoned.

**Status and Conservation.** Not globally threatened. Generally common in appropriate habitat. Dependence on wetlands with emergent vegetation renders it somewhat vulnerable; many local populations greatly reduced or extirpated by habitat destruction. Andean and coastal Pacific races particularly vulnerable.

**Bibliography.** Araya & Chester (1993), Belton (1984), Bond (1945), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Chesser (1994), Cory & Hellmayr (1925), Cuello (1985), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Hayes (1995), Johnson (1967), Koepeke (1954, 1970), MacDonald (1933), Mason (1985), Mazar Barnett (1999), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bö (1987), Olrog (1948, 1963a), Parker *et al.* (1982), de la Peña (1987, 1988, 1996), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ribero (1991), Ridgely & Tudor (1994), San Martín (1927), Selater & Hudson (1888), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Taczanowski (1884), Wetmore (1926), Willis (1992b), Zimmer (1935b, 1936a), Zotta (1938), Zyskowski & Prum (1999).

## Genus *APHRASTURA* Oberholser, 1899

### 45. Thorn-tailed Rayadito

#### *Aphrastura spinicauda*

**French:** Synallaxe rayadito

**Spanish:** Rayadito Común

**German:** Festland-Stachelschwanzschlüpfer

**Other common names:** Thorn-tailed Creeper

**Taxonomy.** *Motacilla spinicauda* J. F. Gmelin, 1789, Tierra del Fuego.

Affinities of genus uncertain; plumage features suggest possible relationship to *Phleocryptes* and to sympatric *Pygarrhichas*. Close to, and perhaps ancestor of, *A. masafueræ*. Validity of race *bullocki*, described from only two specimens, perhaps requires reconfirmation; also, individuals with ochraceous underparts, thus resembling *fulva*, evidently occur throughout near-shore Chilean islands, suggesting that this ventral pattern may appear independently in insular populations as response to more humid conditions (Gloger's Rule); in addition, population on Diego Ramírez I apparently differs morphologically from typical nominate form; further study

needed in order to clarify geographical limits and validity of races. Three subspecies currently recognized.

**Subspecies and Distribution.**

*A. s. spinicauda* (J. F. Gmelin, 1789) - C & S Chile (S from S Coquimbo) and extreme W Argentina (S from Neuquén) S to Tierra del Fuego, Staten I and Diego Ramírez I; also Falkland Is.

*A. s. bullocki* Chapman, 1934 - Mocha I, off SC Chile.

*A. s. fulva* Angelini, 1905 - Chiloe I, off SC Chile.

**Descriptive notes.** 13-14 cm; 10-13 g. Small, active, acrobatic furnariid. Nominative race has blackish-brown crown, contrasting broad ochraceous supercilium from forehead (where duller) and extending posteriorly to upper back, broad blackish line from lores back to shoulder area; blackish-brown colour of crown extends onto upper back, which otherwise brown; rump brown, uppertail-coverts chestnut; wing-coverts blackish, medians tipped and edged rufous, greater tips whitish; folded wing looks mainly black or blackish; remiges with orange-rufous at bases, buffy brown band across secondaries and tertiaries; tail strongly graduated, distal portions of shafts virtually without barbs and producing very "spiny" appearance, spines c. 20 mm long on central rectrices (also with stiffened shafts), progressively reduced on lateral feathers, only 5 mm long on outer pair, colour pattern distinctive and complex, a mix of blackish, brown, chestnut and rufous; throat white, blending to dull buffy breast and belly, with broad pale brownish sides, rufescent flanks and undertail-coverts; iris dark brown; bill blackish; tarsus and toes greyish. Differs from *A. masafueræ* in smaller size, shorter bill, brighter and more patterned plumage. Sexes alike. Juvenile undescribed. Race *bullocki* is very like nominate, has whitish throat but brownish-buff tinge below; *fulva* has entirely ochraceous underparts, palest on throat. **VOICE.** Song a thin dry trill, variable in duration; calls include high-pitched "zee-zee" or "tzt-tzt", sharp "tic" and metallic "ti ti".

**Habitat.** Southern temperate forest, locally arid lowland scrub; tall humid forest (usually *Nothofagus*) and adjacent second growth; also tussock grass (*Poa flabellata*) or shrubs (e.g. *Berberis*) on islands with little or no arborescent vegetation. Mainly sea-level to 1200 m, locally to 2000 m.

**Food and Feeding.** Arthropods; Diptera and Hymenoptera recorded as taken. Also seen to peck ripe fruits of *Berberis*, *Ribes* and *Gunnera*. Forages in pairs, also in single-species flocks of 4-7 and, occasionally, up to 15 individuals. Often in mixed-species flocks, in which it is the nuclear species. Gleans items from foliage, mosses and lichens, also from branches and trunks, mainly from understorey to canopy; occasionally from ground. Often described as ecologically similar to tits (Paridae) or, sometimes, treecreepers (Certhiidae) of N Hemisphere.

**Breeding.** Season during austral spring-summer; eggs in Nov-Dec and nestlings in Oct-Jan. Presumably monogamous. Nest placed behind loose bark or in hole or crevice in tree, or crack in tree stump, lined with twigs, grass and feathers. Clutch 3-4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to locally abundant in most of range. Occurs in Vicente Pérez Rosales, Nahuelbuta and Cerro La Campana National Parks, in Chile, and Tierra del Fuego National Park, in Argentina. Region inhabited generally has only sparse human population.

**Bibliography.** Araya & Chester (1993), Blondel *et al.* (1984), Canevari *et al.* (1991), Chebez & Bertonatti (1994), Chebez *et al.* (1999), Contreras (1975), Cory & Hellmayr (1925), Crawshaw (1907), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Humphrey *et al.* (1970), Johnson, A.W. (1967, 1972), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), de la Peña (1987, 1988), Pereyra (1951), Philippi *et al.* (1954), Reynolds (1934, 1935), Ridgely & Tudor (1994), Stotz *et al.* (1996), Trimble (1943), Vuilleumier (1967, 1972, 1985, 1991), Wallace (1991).

### 46. Masafuera Rayadito

#### *Aphrastura masafueræ*

**French:** Synallaxe de Masafuera

**Spanish:** Rayadito de Más Afuera

**German:** Insel-Stachelschwanzschlüpfer

**Other common names:** Masafuera Creeper

**Taxonomy.** *Synallaxis Masafueræ* [sic] R. A. Philippi [Krumwiede] and Landbeck, 1866, Alejandro Selkirk I (formerly Más Afuera), Chile.

Affinities of genus uncertain; plumage features suggest possible relationship to *Phleocryptes* and *Pygarrhichas*. Close to *A. spinicauda*, having diverged from that or from common ancestor. Monotypic.

**Distribution.** Alejandro Selkirk I (formerly Más Afuera), in Juan Fernández Is (off Chile).

**Descriptive notes.** 14-15 cm. Has whitish forehead with some narrow rufous streaks, dark dusky brown crown, dull buff-brown supercilium poorly defined; back dull brown, rump rufous-brown; wing-coverts mostly blackish, tips tawny (whiter when plumage worn), remiges blackish with dull rufous at bases; tail graduated, shafts stiff, barbs reduced distally and giving "spiny" appearance, webs rufous, blackish bases on all but central pair; throat whitish, breast and belly dull buffy grey-brown, tinged rufescent, flanks and undertail-coverts rufescent; iris brown; upper mandible horn-brown or mostly horn-tinged yellowish-white (source of variation unknown); lower mandible yellowish-horn; tarsus and toes horn-grey. Differs from *A. spinicauda* in slightly larger size, longer bill, duller plumage. Sexes similar, possibly differ in colours of upper mandible and crown. Juvenile undescribed. **VOICE.** Call a low churring "trrrrr" c. 1-2 seconds long, singly or repeated.

**Habitat.** Semi-humid/humid montane scrub; wooded areas dominated by the tree-fern *Dicksonia externa*, with ground mostly covered by the fern *Lophosoria quadripinnata*, often along streams. At 800-1300 m; occasionally down to 600 m or lower in austral winter.

**Food and Feeding.** Diet little known; probably consists mostly of arthropods. Almost always occurs in pairs. Forages in understorey, and also occasionally on ground in leaf litter. Acrobati-

cally gleans items from fern foliage and fronds, hanging upside-down like tits (Paridae); also seeks food on mosses and lichens that grow on the tree *Drimys confertifolia* (Winteraceae). Moves through ferns slowly, by hops and short flights; also runs up trunks in manner of treecreepers (Certhiidae).

**Breeding.** Season at least from early Dec to late Jan. Nest situated in natural cavity in steep rock face, usually more than 5 m above surrounding ground; entrance hole extremely small, c. 3 cm in diameter. Both adults feed chicks in equal proportions; nestlings fed on average 36 times per hour, 15 hours per day.

**Movements.** Resident; some downslope movement in winter.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Juan Fernández Islands EBA. Total population thought to number 500-1000 birds in mid-1980s; more recent estimates, based on transect counts, give much lower figure, only c. 140 individuals in 2002. As the

entire Juan Fernández archipelago is a biosphere reserve, there are no foreseeable threats from development. The habitat on Alejandro Selkirk is, however, threatened by the trampling and grazing of introduced goats (*Capra*), and the rayadito is not present where habitat degradation is severe; introduced predators, including rats (*Rattus*) and cats, are presumably also a major threat; fires lit by humans are an additional problem, leading to further loss of habitat. Indigenous race *exsul* of Red-backed Hawk (*Buteo polyosoma*) preys frequently on both adults and nestlings. Conservation status almost certainly merits reassessment; it should probably be reclassified as Endangered, or perhaps even Critical.

## Genus *LEPTASTHENURA* Reichenbach, 1853

### 47. Brown-capped Tit-spinetail

#### *Leptasthenura fuliginiceps*

**French:** Synallaxe à tête brune **German:** Braunkappen-Meischlupfer **Spanish:** Tijeral Canelo

**Taxonomy.** *Synallaxis fuliginiceps* d'Orbigny and Lafresnaye, 1837, Sicasica, La Paz, Bolivia. Sister-species relationship with *L. yanacensis* suggested by similarities in plumage and tail pattern; simple plumage pattern and tail structure interpreted as indicating that both occupy a basal position in genus. Validity of race *paranensis* requires confirmation by quantitative analysis of apparent plumage differences. Two subspecies recognized.

#### **Subspecies and Distribution.**

*L. f. fuliginiceps* (d'Orbigny & Lafresnaye, 1837) - Andes of Bolivia (S La Paz S to Potosí and Tarija).

*L. f. paranensis* P. L. Selater, 1862 - NW & WC Argentina (Andes from Jujuy and Salta S to Mendoza, and mountains of Córdoba and San Luis).

**Descriptive notes.** 15-16 cm; 9-13 g. Small, slender, short-billed, long-tailed, acrobatic furnariid. Has pale, dull buff supercilia meeting across forehead, rather plain brownish face; crown brown, upper back paler and duller brown, becoming rufescent on lower back and uppertail-coverts; wings mostly rufous; tail long, strongly graduated, central rectrices with slightly thickened shafts and barbs progressively narrowing towards tip, giving forked, "spiny" appearance (less deeply "forked" than in most congeners), rufous; underparts dull pale tawny brownish, palest in centre of throat, with flanks and undertail-coverts tinged

rufescent; iris brown to dark brown; upper mandible black to dusky brownish-horn, lower mandible uniform horn to pearl-grey with dusky tip; tarsus and toes olive greenish, greyish-olive or grey. Sexes alike. Juvenile has slightly mottled breast, less distinctly defined crown, and rounded tips to rectrices. Race *paranensis* is apparently paler and greyer below and has duller, less brownish back than nominate. **VOICE.** Song apparently not described; call a faint insect-like "pree" given every 1-2 seconds.

**Habitat.** Arid montane scrub, semi-humid/humid montane scrub, *Polylepis* woodland; semi-humid woodland, forest edge; in montane scrub, occurs especially in ravines; *Polylepis australis* woodland in W Argentina. At 1500-3900 m, locally to 4200 m; mostly 1000-2500 m in Argentina (*paranensis*).

**Food and Feeding.** Arthropods; recorded diet items include Coleoptera eggs. Usually in pairs or small flocks; regularly in mixed-species flocks. Forages from understorey up to canopy. Gleans items from foliage and branches, occasionally vertical trunks; often hangs upside-down acrobatically. Seen to forage in direct association with *L. yanacensis* in Argentina.

**Breeding.** Season during austral spring-summer; eggs in Feb in S Peru and NW Argentina; nestlings in Jan-Feb and Apr and fledglings in Feb and Apr in Argentina. Presumably monogamous. Nest a ball of plant material lined with soft plant fibres, small twigs, down and feathers, placed in narrow crevice in rock or building. Clutch 2-3 eggs.

**Movements.** Mainly resident; some post-breeding downslope movement by S populations (*paranensis*).

**Status and Conservation.** Not globally threatened. Uncommon to common throughout range. Not well known.

**Bibliography.** Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hoy (1968b), Johnson (1967), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Nellar (1993), Nores & Yzurieta (1981), Nores *et al.* (1983), Olrog (1956, 1963a), de la Peña (1988), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Salvador (1988), Stotz *et al.* (1996), Wetmore (1926).

### 48. Tawny Tit-spinetail

#### *Leptasthenura yanacensis*

**French:** Synallaxe fauve **German:** Roststirn-Meischlupfer **Spanish:** Tijeral de Yánc

**Taxonomy.** *Leptasthenura yanacensis* Carriker, 1933, Yánc, 15,000 feet [c. 4570 m], Ancash, Peru. Sister-species relationship with *L. fuliginiceps* suggested by similarities in plumage and tail pattern; simple plumage pattern and tail structure interpreted as indicating that both occupy a basal position in genus. Population in Cochabamba, in Bolivia, with whitish supercilium and paler underparts than N populations, almost certainly represents an undescribed taxon; specimen material from NW Argentina lacking. Monotypic.

**Distribution.** W & SE Peru (Ancash, N Lima, and E Andes in Cuzco and Puno) S to N Bolivia (La Paz, Cochabamba, Potosí, Tarija) and NW Argentina (Jujuy, Salta).

**Descriptive notes.** 15-16 cm; 10-12 g. Uniformly brightly coloured, unstreaked tit-spinetail with relatively long, thin bill. Has pale brown narrow supercilium (whitish in Cochabamba, in Bolivia), dark chestnut forehead, blending to duller dark brown crown and to reddish-brown back; wings mostly rufous-chestnut; uppertail-coverts and tail rufous-chestnut; tail long, strongly graduated, only 10 rectrices (all congeners have 12), central pair with slightly thickened shafts, barbs only slightly reduced on distal portions (shallowest "fork" in genus); fairly uniform tawny ochraceous below (paler in Cochabamba), palest on chin, darkest on flanks and undertail-coverts; iris brown to dark brown; bill black to dark greyish, sometimes pinkish base of lower mandible; tarsus and toes dark brown to olive-brown to grey (source of variation unknown). Sexes alike. Juvenile has faintly barred breast, sometimes lacks rufous on forehead, rectrices blunt-tipped. **VOICE.** Song a rough,

woodland in Bolivia, where it often fills "sentinel" role in such flocks. Forages from understorey up to canopy. Gleans food items from foliage and small branches, sometimes vertical trunks, starting from near ground; often hangs acrobatically upside-down; occasionally forages on rocks and on grassy slopes. Observed to forage in direct association with *L. fuliginiceps* in Argentina.

**Breeding.** Season probably begins at start of wet season in S Andes, about Oct-Nov; nest-building observed in Dec in S Bolivia and NW Argentina; eggs in Nov in SE Peru (Cuzco). Monogamous. Nest a dome-shaped ball of dried grass c. 25 cm in diameter, side entrance, lined with hairs, plant fibres and down, and feathers, placed 2-2.5 m up on horizontal branch of *Polylepis* tree. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Rare to locally common. Only data on densities from Bolivian *Polylepis* woodland, where widely overlapping home ranges, and average home-range size 5-7 ha. Occurs in Machu Picchu Historical Sanctuary, in Peru. First discovered in Argentina in 1996, and currently known to occur at at least six localities in that country. Main threats are heavy grazing by domestic livestock and uncontrolled fires, both of which prevent regeneration of woodland; cutting for timber, charcoal and firewood also a major problem. Agricultural intensification and planting of exotic trees, especially eucalyptus (*Eucalyptus*), also lead to soil erosion and general destruction and degradation of habitat.

**Bibliography.** Carriker (1933), Chebez *et al.* (1999), Fjeldså & Krabbe (1986, 1990), Fjeldså & Maijer (1996), Herzog *et al.* (2002), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Mazar Barnett, Clark *et al.* (1998), Nores & Yzurieta (1984), Parker (1981), Parker & O'Neill (1980), Parker *et al.* (1982), Pearman (2001), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1969), Walker (2001).

### 49. Tufted Tit-spinetail

#### *Leptasthenura platensis*

**French:** Synallaxe de la Plata **German:** Haubenmeischlupfer **Spanish:** Tijeral Copetón

**Taxonomy.** *Leptasthenura platensis* Reichenbach, 1853, Río de la Plata, Argentina.

Plumage similarities have suggested to some that this and mostly parapatric *L. aegithaloides* are sister-species. Monotypic.

**Distribution.** N & C Argentina (Salta, Formosa and Corrientes S to N Chubut and S Buenos Aires), extreme SE Brazil (extreme W Rio Grande do Sul) and Uruguay; recorded also in S Paraguay.

**Descriptive notes.** 16-17 cm; 10-12 g. Typical tit-spinetail, but with short crest. Has thin pale supercilium, dull greyish-brown face obscurely marked brownish; crown and crest dark brown, streaked paler (pale feather shafts); back dull greyish-brown, uppertail-coverts paler, tinged tawny; wings mostly greyish-brown, coverts tipped paler, tertials edged paler; tail long, strongly graduated, central rectrices with slightly thickened shafts and with barbs narrowing towards tip, barbs greatly reduced on distal 3 cm of central rectrices (where inner webs deeply emarginated), mostly dark fuscous, webs of outer rectrices dull rufous

distally; throat to upper breast whitish, obscurely marked dark brownish, rest of underparts pale greyish-brown, slightly darker on flanks and undertail-coverts; iris brown; bill black, pale base of lower mandible; tarsus and toes dark olive-green. Sexes alike. Juvenile lacks crest, has crown and breast much less distinctly marked, back darker and faintly spotted, tail shorter with rectrices blunter.

**VOICE.** Song an accelerating, descending trill introduced by distinct sharp notes, "tsi, tsirrrrr". Calls an assortment of high-pitched, dry, squeaky notes, most commonly a series of short notes followed by sharp trill, e.g. "pit-pit-pit ... prrr", also described as "tee-ee-ee".

**Habitat.** Gallery forest, riparian thickets, arid lowland scrub; dry woodland (e.g. *Prosopis flexuosa*) and adjacent brushy areas and monte desert (e.g. with *Larrea divaricata*, *L. cuneifolia*, *Capparis atamisquea*, *Condalia microphylla*), also *espinillo* (*Prosopis-Acacia*) woodland. To 1000 m.

**Food and Feeding.** Arthropods; recorded items are Coleoptera larvae and small spiders. Usually in pairs or in small flocks, possibly family groups. Forages from understorey up to canopy. Gleans items from foliage, small branches and twigs; often hangs upside-down acrobatically.

**Breeding.** Season during austral spring-summer; eggs in Sept-Dec and nestlings in Oct-Dec in Argentina; nestlings in Oct in S Brazil. Presumably monogamous. Nest a cup of twigs, grasses, feathers and hairs, placed in natural tree cavity or old hole of woodpecker, such as Chequered Woodpecker (*Picoides mixtus*), or in old nest of other furnariid (*Furnarius rufus*, *F. cristatus*, *Schoeniophylax phryganophilus*, *Synallaxis frontalis*, *Cranioleuca pyrrhophia*, *Phacellodomus striatocollis*, *Anumbius annumbi* or *Coryphistera alaudina*). Clutch 2-4 eggs, possibly sometimes 6; incubation period c. 14-15 days; chicks fed by both parents, fledging period c. 15-16 days.

**Movements.** Resident; some extralimital records suggest a little seasonal movement or wandering.

**Status and Conservation.** Not globally threatened. Common in much of range. Recorded in Ybicui National Park, in Paraguay; status in Paraguay, however, requires further investigation.

**Bibliography.** Anon. (2003d), Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Cueto *et al.* (1997), Hayes (1995), Mason (1985), Mazar Barnett & Pearman (2001), Narosky & Di

Giacomo (1993), Narosky *et al.* (1983), Navas & Bó (1987), Nellar (1993), Nores *et al.* (1983), Ochoa (1971), Olrog (1956, 1963a), Partridge (1953), de la Peña (1987, 1988, 1996, 1997), Pinto (1978), Ridgely & Tudor (1994), Salvador (1988), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Vuilleumier (1993a), Wetmore (1926).

## 50. Plain-mantled Tit-spinetail

### *Leptasthenura aegithaloides*

**French:** Synallaxe mésange **German:** Zimtspiegel-Meischenschlüpfer **Spanish:** Tijeral Colinegro

**Taxonomy.** *Synallaxis* [sic] *Aegithaloides* Kittlitz, 1830, hills near Valparaíso, Chile.

Plumage similarities have suggested to some authors that this and *L. striolata* are sister-species, and to others that this and mostly parapatric *L. platensis* are sister-species. Geographical variation in colour follows Gloger's Rule, with populations from arid areas usually the palest in coloration. Four subspecies recognized.

#### Subspecies and Distribution

*L. a. griseescens* Hellmayr, 1925 - coastal slope of S Peru (Arequipa S to Tacna) and N Chile (Tarapacá S to Atacama).

*L. a. berlepschi* Hartert, 1909 - Andes of S Peru (C Puno, E Tacna), N Chile (Tarapacá, Antofagasta), W Bolivia (La Paz S to Potosí) and NW Argentina (Jujuy S to Catamarca).

*L. a. aegithaloides* (Kittlitz, 1830) - C Chile (S Coquimbo S to N Aisén).

*L. a. pallida* Dabbene, 1920 - breeds W & S Argentina (La Rioja, S La Pampa and SW Buenos Aires S to Santa Cruz) and S Chile (EC Aisén, NE Magallanes); S populations migrate N in winter to N & C Argentina (Catamarca, Tucumán, E Buenos Aires).

**Descriptive notes.** 14-15 cm; 8-13 g. Typical tit-spinetail. N nominate race has white supercilium, dark brownish face with whitish streaking, streaks continuing to neck and malar area; crown dark brown, becoming paler posteriorly, with sharply defined broad golden-tawny streaks, hindneck with greyish-white streaks; back to uppertail-coverts dull brownish; upperwing-coverts dull brownish with dull rufous margins, remiges dull fuscous with dark rufous bases; tail long, strongly graduated, rectrices stiffened basally, elongated central pair with inner webs deeply emarginated (producing deeply forked appearance), fuscous brown with paler margins; throat whitish with some dark margins, these increasing along lower throat and to upper breast, rest of breast dull greyish-brown, belly, flanks and undertail-coverts slightly paler; iris brown; upper mandible blackish to dark grey-brown, lower mandible dark horn to greenish-grey, sometimes blackish tip; tarsus and toes grey to dark greyish-brown or blackish. Sexes alike. Juvenile has crown streaks and throat markings indistinct, back lightly spotted, tips of rectrices rounded. Race *griseescens* is paler throughout, has broader and paler crownstreaks, greyer back, more buffy rump, paler edges to wing-coverts, paler and greyer underparts; *berlepschi* is slightly larger than previous, back browner, tail markings buffy rather than greyish, underparts more buffy and lacking grey tones; *pallida* differs from nominate in slightly paler appearance, primaries edged whitish, rufous wing patch smaller. Voice. Song a high-pitched descending, broken trill lasting 2-3 seconds; also, frequently gives shorter, lower-pitched nasal trill, "prrr", and assortment of trills during interactions.

**Habitat.** Arid lowland scrub, arid montane scrub, monte woodland and scrub (e.g. *Baccharis tola*), matorral, often on rocky slopes with patches of brush; also scrub (e.g. *Atriplex*) on saltflats, and thorny dry woods; sometimes gardens and oases in non-breeding season. From near sea-level up to 4500 m.

**Food and Feeding.** Arthropods. Usually forages in pairs or in small groups, possibly family parties; in single-species flocks of up to 40 individuals in non-breeding season; regularly joins mixed-species flocks. Seeks food from understorey up to canopy. Gleans items from foliage and branches, using tail for support and balance; often hangs upside-down acrobatically; occasionally forages on grass and ground.

**Breeding.** Season during austral spring-summer; eggs in Dec in S Bolivia, Sept-Oct in S & E Argentina and C Chile, Oct-Nov in N Chile, and Dec in W & Feb in NW Argentina; nestlings in Nov in S and Feb in NW Argentina; fledglings in Feb-Mar in Chile and NW Argentina. Presumably monogamous. Nest a cup of small twigs, hairs and feathers c. 8-12 cm in diameter, placed in hole in small tree or large cactus, in crevice in rocks, cliff, dirt bank or building, or in abandoned domed nest of other bird (e.g. *Asthenes*). Clutch 2-4 eggs.

**Movements.** Mostly resident, but partially migratory in S; considerable downslope movement and local dispersal after breeding. Race *griseescens* disperses between oases separated by at least 50 km of unvegetated desert. S populations of *pallida* undertake post-breeding migration N to N & C Argentina, but seasonal movements not well understood.

**Status and Conservation.** Not globally threatened. Fairly common in much of its range. Occurs in Cerro La Campana and Nahuelbuta National Parks, in Chile. Appears able to tolerate modest habitat degradation.

**Bibliography.** Anon. (2003d), Araya & Chester (1993), Bond (1945), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1975, 1978), Cory & Hellmayr (1925), Cueto *et al.* (1997), Dabbene (1920), Fjeldsá & Krabbe (1990), Fraga & Narosky (1985), Grigera *et al.* (1996), Johnson (1967), Koeckpe (1958, 1963), Krabbe *et al.* (1996), Lönnberg (1903), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Nores *et al.* (1983), Olrog (1948, 1963a), Parker *et al.* (1982), Peña (1961), de la Peña (1987, 1988), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ribero (1991), Ridgely & Tudor (1994), Stotz *et al.* (1996), Taczanowski (1884), Vuilleumier (1993a), Wetmore (1926).

## 51. Striolated Tit-spinetail

### *Leptasthenura striolata*

**French:** Synallaxe striolé **German:** Isabellstreifen-Meischenschlüpfer **Spanish:** Tijeral Brasileño

**Taxonomy.** *Synallaxis striolata* Pelzel, 1856, Curitiba, Paraná, Brazil.

Plumage similarities have suggested to some that this and *L. aegithaloides* are sister-species. Monotypic.

**Distribution.** SE Brazil from Paraná S to N Rio Grande do Sul.

**Descriptive notes.** 15-16 cm; 10-11 g. Has black crown with buff streaks, buff-whitish supercilium; upperparts brown, back with conspicuous buff streaks; wings dark brown with paler margins, rufous bases of remiges; tail long, strongly graduated, rectrices slightly stiffened basally, inner webs

in interior of tall forest, usually at edge. At 500-1100 m; one record near coast.

**Food and Feeding.** Arthropods. Usually forages in pairs, occasionally in mixed-species flocks, from understorey to canopy. Gleans food items from foliage and branches; often hangs upside-down acrobatically.

**Breeding.** Season during austral spring-summer; nestlings in Dec. Monogamous. Nest a platform of twigs mixed with moss, lined with feathers, placed in natural cavity or old hole of woodpecker (Picidae) 1-4-6 m up in tree, or in other cavity (e.g. inside cow skull placed above ground). Clutch size not documented; both sexes feed nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Fairly common to common within its limited range, and evidently common in human-disturbed habitats. Uncommon in Aparados da Serra National Park.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Belton (1984), Bencke *et al.* (2001), Cordeiro (2001), Cory & Hellmayr (1925), Parker & Goerck (1997), Pinto (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 52. Rusty-crowned Tit-spinetail

### *Leptasthenura pileata*

**French:** Synallaxe couronné **German:** Rostkappen-Meischenschlüpfer **Spanish:** Tijeral Coronado  
**Other common names:** Streak-crowned Tit-spinetail (*cajabambae*)

**Taxonomy.** *Leptasthenura pileata* P. L. Sclater, 1881, western slope of the coastal cordillera above Lima, 8000 feet [c. 2440 m], Peru.

Forms a superspecies with *L. xenothorax*, and considered conspecific by some authors; together, the two are presumably most closely related to *L. striata*. Race *cajabambae* has alternatively been considered a race of *L. striata*, but may merit species rank. Three subspecies recognized.

#### Subspecies and Distribution

*L. p. cajabambae* Chapman, 1921 - N & C Peru (Cajamarca S to Ancash, and dry interior slopes of E Andes S to Junín).

*L. p. pileata* P. L. Sclater, 1881 - WC Peru (Chillón and Rimac Valleys, in Lima).

*L. p. latistriata* Koeckpe, 1965 - SC Peru (W Huancavelica, Ayacucho).

**Descriptive notes.** 17-18 cm; 9-13 g. Typical tit-spinetail. N nominate race has thin pale supercilium narrowly bordered black above, face streaked blackish and whitish; crown fairly dark rufous-chestnut, contrasting sharply with dull brown back, latter with prominent whitish streaks widely bordered dark brown, streaks much fainter on rump but conspicuous again on uppertail-coverts; wings dark fuscous, dull rufescent edges of wing-coverts, paler tawny patch at base of primaries; tail long, strongly graduated, central rectrices with slightly thickened shafts and progressively narrower barbs, barbs greatly reduced on distal

part (inner webs deeply emarginated), mostly dark fuscous, inner webs of outer rectrices with prominent pale grey-brown spots; throat and upper breast dull greyish-white with dark spots and short streaks, rest of breast darker brownish-grey with paler broad streaks, belly slightly paler with streaks fainter, streaking more prominent again on undertail-coverts; iris brown to dark brown; bill black to dark horn, base of lower mandible pale horn, pinkish or yellowish; tarsus and toes blackish to brownish-horn. Distinguished from *L. xenothorax* by duller, darker crown, more heavily streaked back, longer tail, less strongly patterned throat, duller and more streaked below. Sexes alike. Juvenile undescribed. Race *cajabambae* has deep cinnamon crown with blackish stripes, greyish edges of upperwing-coverts, throat to breast paler and less distinctly streaked, appearing more mottled; *latistriata* is more heavily streaked above and on breast, greyer below. Voice. Song a slightly accelerating trill that increases in volume, 2 seconds long, repeated at intervals of 3-6 seconds; also slower, slightly descending trill and sharp "rick teek teek". Contact call "tsee" or "tsak".

**Habitat.** Arid montane scrub; riparian thickets and woodland edge; more humid montane scrub, *Alnus* thickets and *Polylepis* woodland in N & C Peru (*cajabambae*). From 2000 m to 4300 m, mostly 2500-3500 m.

**Food and Feeding.** Arthropods. Foraging sociality undescribed, probably in pairs. Forages from understorey up to canopy. Gleans food items from foliage and small branches; often hangs upside-down acrobatically.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Peruvian High Andes EBA. Fairly common in most of its range. Relatively poorly known species.

**Bibliography.** Bond (1945), Carriker (1933), Cory & Hellmayr (1925), Fjeldsá & Krabbe (1990), Hellmayr (1932), Koeckpe (1954, 1958, 1961a, 1970), Parker (1981), Parker *et al.* (1982), Ridgely & Tudor (1994), Schultenber (1986), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 53. White-browed Tit-spinetail

### *Leptasthenura xenothorax*

**French:** Synallaxe à gorge rayée **Spanish:** Tijeral Cejiblanco  
**German:** Graubauch-Meischenschlüpfer

**Taxonomy.** *Leptasthenura xenothorax* Chapman, 1921, Torontoy, Urubamba Valley, Cuzco, Peru. Forms a superspecies with *L. pileata*, and considered conspecific by some authors; together, the two presumably most closely related to *L. striata*. Monotypic.

**Distribution.** Andes of S Peru (Apuimac, Cuzco).

**Descriptive notes.** 17-18 cm; 13 g. Has white supercilium narrowly bordered black above, face streaked blackish and whitish; crown bright rufous-chestnut, contrasting with dull brown upperparts, back with whitish streaks bordered dark brown, rump with much fainter streaks, conspicuous streaks on uppertail-coverts; wings dark fuscous, dull rufescent edges of wing-coverts, paler tawny patch across flight-feathers; tail long, strongly graduated, central rectrices with slightly thickened shafts and progressively narrower barbs, barbs greatly reduced on distal part (inner webs deeply emarginated), mostly dark fuscous to blackish; throat to upper breast whitish, heavily mottled black, lower breast to undertail-coverts rather uniform pale grey-brown; iris brown; bill black, pinkish base of lower mandible; tarsus and toes black. Differs from *L. pileata* in brighter crown, less streaked upperparts, somewhat shorter tail, more heavily patterned throat, paler and plainer below. Sexes alike. Juvenile undescribed. Voice. Song a high-pitched trill lasting 2 seconds (longer when agitated), sometimes 1-4 introductory notes; also gives other trilled and rattling notes. Contact call "check" or "tjit", very similar to call of *L. pileata*.

**Habitat.** *Polylepis* woodland, primarily with *Gynoxys*; occasionally in adjacent scrub, e.g. *Escallonia*. At 3600-4550 m.

**Food and Feeding.** Arthropods. Usually in pairs or in groups of 3-5, possibly family parties; occasionally in mixed-species flocks. Forages from understorey to canopy, usually 0.5-4 m above ground. Gleans items from mosses, lichens, bark, dead branches and dead leaves, rarely from foliage; often hangs upside-down acrobatically.

**Breeding.** Virtually nothing known. Adult seen attending nest-hole in *Polylepis* tree, in Nov.

**Movements.** Resident; some limited downslope movement during snowstorms.

**Status and Conservation.** ENDANGERED. Restricted-range species: present in Peruvian High Andes EBA. Uncommon to locally common within very limited range; known from just a few localities, including Machu Picchu Historical Sanctuary. Rare in Vilcabamba relict forest, where density 4-8 birds/5 ha. Estimates of total population vary from only a few hundred individuals to, possibly, 1500; c. 30-50 birds at Abra Málaga (Cuzco). *Polylepis* woodland is an endangered habitat in most of the Andes because of cutting for firewood, and this species' existence depends, therefore, on some of remaining stands of *Polylepis* being preserved within its small range; regeneration of woodland often prevented by grazing and uncontrolled fires. Persists in, or at least ranges into, tiny degraded forest fragments as small as 0.25 ha in size.

**Bibliography.** Chapman (1921a, 1921b), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1925), Engblom *et al.* (2002), Fjeldsa (1987, 1991), Fjeldsa & Kessler (1996), Fjeldsa & Krabbe (1990), Fjeldsa *et al.* (1987), Parker & O'Neill (1980), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Walker (2001), Wege & Long (1995).

## 54. Streaked Tit-spinetail

### *Leptasthenura striata*

**French:** Synallaxe strié **German:** Rostspiegel-Meischenschlüpfer **Spanish:** Tijeral Listado  
**Other common names:** Streak-backed Tit-spinetail

**Taxonomy.** *Synallaxis striata* R. A. Philippi [Krumwiede] and Landbeck, 1863, Cordillera of Arica, "Peru" (= Chile?).

Plumage features suggest close relationship to *L. pileata* and *L. xenothorax*. Similarities in plumage to allopatric population of former have led to taxonomic confusion between the two; differences greatest where the two are sympatric, suggesting character displacement. Three subspecies recognized.

#### Subspecies and Distribution.

*L. s. supercilialis* Hellmayr, 1932 - W Andes of W Peru (Ancash, Lima).

*L. s. albigularis* Morrison, 1938 - W Andes in Huancavelica (SW Peru).

*L. s. striata* (R. A. Philippi [Krumwiede] & Landbeck, 1863) - Andes of extreme SW Peru (Arequipa S to Tacna) and NW Chile (Tarapacá).

**Descriptive notes.** 15-16 cm; 8-10 g. One of the smallest tit-spinetails. N nominate race has whitish supercilium, brownish auriculars faintly streaked; crown pale rufous with conspicuous narrow black streaks; back dark brownish with bold whitish streaks, rump paler brown with faint streaks, uppertail-coverts dark brown with tawny streaks; wings dark brown, tawny edges of wing-coverts, broad tawny-rufous patch at base of primaries; tail long, strongly graduated, central rectrices with slightly thickened shafts and barbs narrowing towards tip, giving strongly forked appearance, dark fuscous, pale brown areas on inner webs, pale edges on outer rectrices; throat whitish with indistinct blackish flecks, blending to greyish breast with faint streaks, belly and undertail-coverts whitish, blending to grey-brown flanks; iris brown to dark brown; bill black, base of lower mandible yellowish or pinkish; tarsus and toes black to dark grey. Sexes alike. Juvenile has grey-brown crown barely streaked, wings more extensively rufous, breast feathers with dark edges. Race *superciliaris* has more conspicuous supercilium; *albigularis* has supercilium greatly reduced or absent, plain throat lacking spots, unstreaked rump and uppertail-coverts. Voice. Song a long descending trill; contact call "trit".

**Habitat.** Arid montane scrub (e.g. *Baccharis*), sometimes quite sparse, often with cacti; also *Polylepis* woodland in S of range (nominate race). Mainly 2000-4000 m; primarily 1500-2500 m, locally to near sea-level, in N of range (*superciliaris*).

**Food and Feeding.** Arthropods. Feeding sociality undescribed; likely to be in pairs or small groups, as with congeners. Forages from understorey up to canopy. Gleans items from foliage and small branches; often hangs upside-down acrobatically. Occasionally picks prey from ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in most of range. Relatively poorly known. Possibly at some risk from habitat loss in S parts of range.

**Bibliography.** Araya & Chester (1993), Carriker (1933), Cory & Hellmayr (1925), Fjeldsa & Krabbe (1990), Hellmayr (1932), Johnson, A. W. (1967, 1972), Koepecke (1954, 1958, 1970), Morrison (1939), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stotz *et al.* (1996), Zimmer (1930).

## 55. Andean Tit-spinetail

### *Leptasthenura andicola*

**French:** Synallaxe des Andes

**German:** Dunkelbrauner Meischenschlüpfer

**Spanish:** Tijeral Andino

**Taxonomy.** *Leptasthenura andicola* P. L. Selater, 1870, Panza, southern slope of Chimborazo, Ecuador.

Plumage similarities suggest to some that this species is sister to a group that consists of *L. pileata*, *L. xenothorax* and *L. striata*. Proposed race *boliviana* (N Bolivia) described as like *peruviana* but with back streaks wider, outer webs of secondaries blacker and lacking rufous, and rectrices blacker and wider, but considered not diagnosable by later authors. Five subspecies recognized.

#### Subspecies and Distribution.

*L. a. extima* Todd, 1916 - N Colombia (Santa Marta Mts).

*L. a. certhia* (Madarász, 1903) - Andes of W Venezuela (Mérida, Trujillo, presumably also Táchira).

*L. a. exterior* Todd, 1919 - E Andes of N Colombia (Boyacá, Cundinamarca).

*L. a. andicola* P. L. Selater, 1870 - C Andes of Colombia (S from Tolima) S to Ecuador (S to N Azuay on W slope and to Cotopaxi and SW Napo on E slope, also in S Zamora-Chinchepe).

*L. a. peruviana* Chapman, 1919 - Andes of W & S Peru (Ancash S locally to Arequipa and Puno) and N Bolivia (La Paz); sight report from N Chile (Tarapacá).

**Descriptive notes.** 16-17 cm; 15-16 g. Dark-est and most heavily marked tit-spinetail. N nominate race has conspicuous broad whitish supercilium that meet across forehead, brownish auriculars; crown rufous with black streaks, upperparts blackish-brown with conspicuous broad whitish streaks; wings dark brownish, faint rufescent edges of wing-coverts; tail long, strongly graduated, central rectrices with slightly thickened shafts and barbs narrowing towards tip, appearing forked, blackish-brown, buff outer webs except for central rectrices; throat white with short dark streaks; underparts brownish with conspicuous broad whitish streaks, flanks and lower belly paler with streaks less sharp; iris dark brown to reddish-brown; bill blackish, slightly paler base of lower mandible; tarsus and toes blackish. Sexes alike. Juvenile has crown streaking darker or reduced, belly mottled rather than streaked. Race *extima* is smaller, has broader and more rufescent edges of wing-coverts, conspicuous rufous wingband, paler crown streaks, narrower and more buffy supercilium, broader and whiter back streaks, more spots on throat, more buffy belly virtually unstreaked; *certhia* is like previous, but wingband reduced, wing-coverts nearly lack edgings, crownstreaks paler, belly greyer, has whiter supercilium, back streaks, throat and chest; *exterior* has brighter rufous crown with narrower streaks, broader white supercilium and back streaks, rufous-tinged auriculars, rufous wing-covert edges, large rufous wing patch, whiter throat, brownish belly tinged rufescent; *peruviana* differs from nominate in much paler crown with narrow black feather margins, paler and more faintly streaked auriculars, more conspicuously cinnamon-edged wing-coverts, more strongly dark-margined ventral streaking. Voice. Song described as high-pitched descending series of notes that starts and finishes with a trill, also as hesitating series of short, high-pitched trills; also gives monotonic trill lasting 2 seconds, and weak, high-pitched "tee-zit". Contact call "zik", "tzi-dik" or "tik".

**Habitat.** Arid, semi-humid/humid montane scrub, páramo grassland, and *Polylepis* woodland; scrubby woodland, patches of scrub on steep slopes, and bushy páramo. At 3000-4500 m.

**Food and Feeding.** Arthropods. Usually in pairs or small groups, occasionally in mixed-species flocks. Forages at all levels. Gleans items from shrub foliage, small branches and their epiphytes, *Espeletia* foliage and seedheads, and from flowers (especially *Senecio*); occasionally hangs upside-down acrobatically.

**Breeding.** Nestlings in Feb and Apr in C & S Peru; fledglings in Nov and May in Venezuela, Sept in C Colombia and Aug in SW Peru. Presumably monogamous. Two nests found; nest is a ball of plant fragments 16 cm in diameter, side entrance, chamber profusely lined with feathers and hair, hidden 1-2 m above ground against trunk of *Puya raimondii* and adjacent debris. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in much of its range; tends to be uncommon to rare in S of range (*peruviana*). Occurs in Puracé National Park, in Colombia, and Cotopaxi National Park and Las Cajas National Recreation Area, in Ecuador.

**Bibliography.** Carriker (1935a), Cory & Hellmayr (1925), Dorst (1957), Fjeldsa & Krabbe (1990), Hilty (2003a), Hilty & Brown (1986), Johnson (1967), Koepecke (1970), Krabbe *et al.* (1997), Meyer de Schauensee (1945), Morrison (1939), Olivares (1969), Parker *et al.* (1982), Pearson (1953), Pfeifer *et al.* (2001), Remsen (2003a), Remsen & Traylor (1989), Renjifo *et al.* (1997), Ribero (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stotz *et al.* (1996), Taczanowski (1884), Todd & Carriker (1922b), Vuilleumier & Ewert (1978), Williams & Tobias (1994).

## 56. Araucaria Tit-spinetail

### *Leptasthenura setaria*

**French:** Synallaxe à filets

**German:** Araukarien-Meischenschlüpfer

**Spanish:** Tijeral de las Araucarias

**Taxonomy.** *Synallaxis setaria* Temminck, 1824, São Paulo, Brazil; error = Castro, Paraná, Brazil. Formerly placed in a monotypic genus *Dendrophylax* or *Bathmidura*. Differs from other members of current genus in bill and tail shapes and in details of plumage pattern. Monotypic.

**Distribution.** SE Brazil (extreme SE Minas Gerais and S Rio de Janeiro to N Rio Grande do Sul) and NE Argentina (Misiones).

**Descriptive notes.** 17-19 cm; 11 g. Relatively long-tailed tit spinetail with short crest, comparatively long and decurved bill. Has thin white supercilium, face streaked black and white; crown

and crest blackish with narrow pale shaft streaks, upperparts reddish-brown, very faint pale shaft streaks on upper back; wings mostly rufous, remiges blackish with broad rufous at bases; tail long, strongly graduated, rectrices stiffened basally, barbs greatly reduced on distal 3 cm of inner rectrices, deeply (4-5 cm) forked, mainly reddish-brown, inner webs of inner three pairs of rectrices darker brown; malar area, throat and upper breast streaked blackish on whitish background, which fades to tawny-buff on breast and below, becoming deeper and richer on flanks; iris brown or grey; bill blackish, pale base of lower mandible; tarsus and toes greyish-green. Sexes alike. Juvenile has less distinct pattern, crown almost unstreaked brownish. **VOICE.** Song a high-pitched descending and accelerating trill of squeaky notes; rapid chattering notes when excited.

**Habitat.** Restricted to *Araucaria angustifolia* trees, whether in forest, woodland or scattered groves; occurs in gardens and in plantations. Recorded at 750-1900 m, generally below 1400 m.

**Food and Feeding.** Arthropods. Usually forages singly or in pairs, from mid-storey to canopy. Gleans food items from *Araucaria* needles and branches; often hangs upside-down acrobatically.

**Breeding.** Season probably during austral spring-summer; nest-building in Sept. Presumably monogamous. Nest a ball of vegetation, including moss, c. 8 cm in diameter, placed high in tree. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Fairly common to common. Common in Aparados da Serra National Park, in Brazil, and in La Araucaria Provincial Park, in Argentina. Its dependence on a single tree species means that any destruction of this represents a threat. In Brazil, most *Araucaria* forest in Paraná has been cleared for agriculture and pasture; in Argentina, has colonized areas newly planted with *Araucaria*, but these often subsequently replaced by pines (*Pinus*). Seems able to adapt to human disturbance as long as *Araucaria* trees not removed.

**Bibliography.** de Andrade (1996), dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Belton (1984, 2003), Boçon (1993), Canevari *et al.* (1991), Chebez (1989, 1994), Chebez *et al.* (1999), Cordeiro (2001), Cory & Hellmayr (1925), Fraga & Narosky (1985), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parker & Goerck (1997), de la Peña (1988), Pinto (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## Genus *SPARTONOICA* J. L. Peters, 1950

### 57. Bay-capped Wren-spinetail

#### *Spartonoica maluroides*

**French:** Synallaxe des marais

**Spanish:** Canastero Enano

**German:** Strichelrücken-Dickichtschlüpfer

**Other common names:** Wren-like Spinetail

**Taxonomy.** *Synallaxis maluroides* d'Orbigny and Lafresnaye, 1837. Buenos Aires, Argentina. Placed in *Synallaxis* by some authors, but thought to be more closely related to *Asthenes* or *Leptasthenura* by others. Monotypic.

**Distribution.** NC Argentina (Chaco and Corrientes S to Córdoba, Mendoza, La Pampa and Buenos Aires), extreme SE Brazil (S Rio Grande do Sul) and Uruguay.

**Descriptive notes.** 12-13 cm; 10-12 g. Typical spinetail in size and shape, but distinctive plumage. Has whitish supercilium, faint dark eyeline and pale brownish face; rufous crown contrasts strongly with conspicuously black-streaked light brown back; wing-coverts brown, centres blackish; remiges black with broad rufous at bases; tail long and strongly graduated, greatly reduced barbs on distal portion of central rectrices creating very "spiny" appearance, mostly brownish; whitish below, blending to buffy brown on sides and flanks; iris whitish to pale bluish; upper mandible blackish, lower mandible whitish to pinkish with dark tip; tarsus and toes light tan. Sexes alike. Juvenile has light brown crown, more buffy, less whitish, underparts, sides slightly mottled brownish, streaks less sharply defined. **VOICE.** Dry mechanical trill 2-3 seconds long, somewhat insect-like; prolonged, thin, weak "tch-tch-tch..."

**Habitat.** Freshwater and brackish marshes with extensive emergent vegetation; also in tall wet grass (*Paspalum quadrifarium*) and boggy areas with *Eryngium*. To 900 m.

**Food and Feeding.** Arthropods; reported items are Coleoptera, Neuroptera and Hymenoptera. Usually forages singly. Gleans food items from marsh vegetation.

**Breeding.** Eggs in Dec and fledgling in Jan. Nest a deep cup or basket of reeds and grass, sheltered from above by dense vegetation, placed at base of dense marsh vegetation or sometimes on ground. Clutch 3-4 eggs. No further information.

**Movements.** Resident; seasonal changes in abundance suggest local movements.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon to fairly common; probably overlooked. Subject to the usual pressures faced by all wetland-dependent species, including drainage of marshes, as well as the drying-out of marshland caused by planting with pines (*Pinus*) and eucalyptus (*Eucalyptus*).

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Comparatore *et al.* (1996), Cory & Hellmayr (1925), Cuello (1985), Di Giacomo *et al.* (2001), Fraga & Narosky (1985), Isacch & Martínez (2001), Maceda *et al.* (1999), Mauricio & Bencke (2000), Mazar Barnett & Pearman (2001), Narosky (1973), Narosky *et al.* (1983), Nores & Yzurieta (1979b), Nores *et al.* (1983), Olrog (1963a), de la Peña (1988), Pereyra (1933), Peters (1950), Pinto (1978), Ridgely & Tudor (1994), Sclater (1890), Sclater & Hudson (1888), Stotz *et al.* (1996), Wetmore (1926), Willis (1992b), Zotta (1936).

## Genus *SYLVIORTHORHYNCHUS*

Des Murs, 1847

### 58. Des Murs's Wiretail

#### *Sylviorthorhynchus desmursii*

**French:** Synallaxe de Des Murs **German:** Fadenschwanzschlüpfer **Spanish:** Tijeral Colilargo  
**Other common names:** Des Murs's Spinetail

**Taxonomy.** *Sylviorthorhynchus Desmursii* Des Murs, 1847, province of Valdivia, particularly near Corral, Chile.

General morphology and tail structure suggest possible relationship to *Schizoeaca*, and nests are at least superficially similar. Monotypic.

**Distribution.** C & S Chile from Aconcagua S to N Magallanes (including Chiloé I and other near-shore islands) and extreme W Argentina (Neuquén S to Santa Cruz).

**Descriptive notes.** 21-23 cm; 9-11g. Small furnariid with preposterously long tail and relatively long, thin, straight bill. Has indistinct pale supercilium, bright orange-rufous forehead blending to rufous-brown crown, upperparts, wings and tail; tail very unusual, only 6 rectrices, central pair extremely long (c. 14 cm) with shafts thickened, barbs very short and somewhat disintegrated, lateral pairs much shorter (c. 8 cm) with shafts not so thick, outer pair tiny (c. 2 cm) and almost hair-like; underparts fairly uniform ochraceous, slightly darker on sides, flanks and undertail-coverts, palest in centre of belly; iris dark brown to blackish-brown; upper mandible blackish, lower mandible whitish with blackish tip; tarsus and toes brownish-horn. Sexes alike. Juvenile undescribed. **VOICE.** A rhythmic, rolling series of repeated "jerr-jerr" notes lasting c. 1-5 seconds; also loud descending trill ending with squeaky notes.

**Habitat.** Southern temperate forest, secondary forest; cool, humid forest dominated by *Nothofagus*, and woodland, especially in or near extensive thickets of *Chusquea* bamboo; to 1000 m.

**Food and Feeding.** Arthropods. Usually forages in pairs, from undergrowth to mid-storey. Gleans items from foliage and twigs.

**Breeding.** Season during austral spring-summer; eggs in Nov and fledglings in Jan-Feb. Presumably monogamous. Nest a ball of dry grass, twiglets, moss, leaves and hair, lined with feathers, with side entrance, placed c. 1 m above ground in dense undergrowth. Clutch 3-4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Status uncertain; appears reasonably common in most of range. Occurs in Puyehué, Nahuelbuta and Cerro La Campana National Parks, in Chile. This species' reluctance to enter open habitats may accentuate effects of forest fragmentation on population structure.

**Bibliography.** Araya & Chester (1993), Barros (1960), Blondel *et al.* (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1975), Cory & Hellmayr (1925), Ijelds & Krabbe (1990), Grigera *et al.* (1996), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1948, 1963a), de la Peña (1988), Pereyra (1951), Radboone (1935), Rasmussen & López (1988), Ridgely & Tudor (1994), Sieving *et al.* (1996), Stotz *et al.* (1996), Vuilleumier (1985, 1991).

PLATE 16

inches 3  
cm 8

# Genus *SCHIZOEACA* Cabanis, 1873

## 59. Perija Thistletail

### *Schizoeaca perijana*

**French:** Synallaxe des Perija **German:** Perija-Distelschwanz **Spanish:** Piscuiz de Perijá

**Taxonomy.** *Schizoeaca perijana* Phelps, Jr., 1977, camp "Frontera 2", Sierra de Perijá, 3000 m, Zulía, Venezuela.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Monotypic.

**Distribution.** Perijá Mts in N Colombia and NW Venezuela.

**Descriptive notes.** 19-22 cm; 16-21 g. Typical thistletail, with long ragged-looking tail, fairly slender bill. Has faint greyish supercilium; crown, upperparts and tail greyish olive-brown, slightly greyer on crown, wing-coverts edged chestnut, bases of remiges chestnut; tail long, strongly graduated, deeply forked, barbs reduced in density and length distally; cinnamon-buff chin spot, otherwise brownish-grey below; iris reddish-brown; upper mandible black, lower mandible greyish with black tip; tarsus and toes grey. Sexes alike. Juvenile undescribed. **VOICE.** Undescribed.

**Habitat.** *Páramo* grassland, in areas of dense undergrowth and adjacent grass in timber-line ecotone, at edge of humid cloudforest; 3000-3400 m.

**Food and Feeding.** Arthropods; berries evidently taken occasionally. Forages singly or in pairs in undergrowth. No information on techniques; probably gleans items from foliage and branches.

**Breeding.** Adults in breeding condition and immatures recorded in Jul. No further information.

**Movements.** Presumably resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Colombian East Andes EBA. Known from very few localities. Small range, c. 150 km<sup>2</sup>, and linear nature of its habitat indicate that total population is rather small, currently estimated to be in the range 250-999 individuals; no data on population trends. Some of the population presumably live within Sierra de Perijá National Park, but that park does not provide effective protection. Habitat at lower elevations, below c. 2000 m, is threatened by a number of human activities, but at higher levels, where this thistletail occurs, habitat not under any immediate threat.

**Bibliography.** Fjeldså & Krabbe (1990), Hilty (2003a), Hilty & Brown (1983, 1986), Phelps (1977b), Remsen (1981), Renjifo *et al.* (1997), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rodríguez & Rojas-Suárez (1995), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 60. Ochre-browed Thistletail

### *Schizoeaca coryi*

**French:** Synallaxe de Cory **German:** Ockerbrauen-Distelschwanz **Spanish:** Piscuiz de Cory  
**Other common names:** Cory's Thistletail

**Taxonomy.** *Synallaxis coryi* Berlepsch, 1888, Andes of Mérida, Venezuela.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Monotypic.

**Distribution.** Andes of W Venezuela (Trujillo S to N Táchira).

**Descriptive notes.** 16-18 cm; 15-18 g. Typical thistletail, with long ragged tail, rather slender bill. Has ochraceous supercilia, darker face; forehead dull ochraceous rufous, blending to olive-brown on crown, upperparts and tail; wings slightly darker, mostly dull reddish-brown; tail long, strongly graduated and deeply forked, with barbs reduced in density and length distally, giving ragged, pointed look; chin spot tawny-rufous, underparts pale grey-brown, almost whitish in centre of belly; iris dark brown to grey-brown; bill dark greyish-brown, pinkish base of lower mandible; tarsus and toes bluish-grey. Sexes alike. Juvenile

undescribed. **VOICE.** Song a dry, rattling trill c. 1.5 seconds long, decelerates at end, "pipipi-pi-pi-pi-pi-pi-pi-pi, pi, pi, pi, pt, pt". Call a high-pitched, nasal "meeow", also squeaky, rodent-like "peeap"; alarm a high "pé-d-deet".

**Habitat.** *Páramo* grassland; dense undergrowth and adjacent grass in timber-line ecotone (especially with *Hypericum*), edge of humid cloudforest, and tall *páramo* vegetation (e.g. *Espeletia*, *Stevia lucida*); also openings in cloudforest at lower elevations. Mainly 3500-4100 m, locally down to 2800 m.

**Food and Feeding.** Mostly arthropods, including Coleoptera and Orthoptera; seeds also recorded in diet. Forages singly or in pairs, occasionally in mixed-species flocks. Gleans prey from foliage and small branches in understorey; occasionally on ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Cordillera de Mérida EBA. Uncommon to fairly common within limited range. Linear nature of habitat occupation suggests that its total population is rather small.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Hilty (2003a), Meyer de Schauensee & Phelps (1978), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier & Ewert (1978).

## 61. White-chinned Thistletail

### *Schizoeaca fuliginosa*

**French:** Synallaxe à menton blanc **German:** Weißkinn-Distelschwanz **Spanish:** Piscuiz Barbiblanco  
**Other common names:** Andean Thistletail, White-chinned Spinetail

**Taxonomy.** *Synallaxis* [sic] *fuliginosa* Lafresnaye, 1843, Colombia = Bogotá.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Is almost certainly paraphyletic with regard to *S. griseomurina* (distribution of which it brackets to the N and S), which is almost certainly more closely related to a parapatric race (probably nominate) of present species than are latter's N and S groups to each other; nominate race shares with that species a plumage feature (white eyering) not found in S races *peruviana* and *plengei*. Diagnosability of *fuliginosa* doubted by some authors, but specimens are readily distinguishable by back colour alone. Four subspecies recognized.

**Subspecies and Distribution.**

*S. f. fuliginosa* (Lafresnaye, 1843) - W Venezuela (SW Táchira), Colombia (E Andes S to Cundinamarca) and Ecuador (S on W slope to Pichincha and on E slope to NW Morona-Santiago).

*S. f. fumigata* Borrero, 1960 - C Andes of Colombia (S Caldas S to Nariño).

*S. f. peruviana* Cory, 1916 - Andes of N Peru (Amazonas).

*S. f. plengei* O'Neill & Parker, 1976 - Andes of C Peru (San Martín S to Pasco).

**Descriptive notes.** 18-20 cm; 14-20 g. Largest thistletail. Nominate race has inconspicuous greyish-tawny supercilium behind eye, whitish eyering, blackish to dark brown lores and face; crown and upperparts dark reddish-brown, wings tinged brighter; tail long, strongly graduated, deeply forked, barbs reduced in density and length distally, producing ragged, pointed look; chin whitish, blending to greyish underparts, tinged brownish on flanks; iris brown to blue-grey or greenish-grey (reported as white in Venezuela); upper mandible black to dark grey, lower mandible dark with pinkish to whitish base; tarsus

and toes blue-grey to grey. Sexes alike. Juvenile undescribed. Races differ from nominate mainly in colour of upperparts: *fuliginosa* has a darker back, also browner, less grey, underparts; *peruviana* is slightly duller above, with darker chin, virtually no eyering, and grey or blue-grey lower mandible; *plengei* is slightly redder above, including tail, with longer and whiter supercilium, dark grey lower throat with whitish streaking. **VOICE.** Song a high-pitched, weak, slightly accelerating and ascending trill that lasts c. 2-3 seconds; also descending series of high-pitched notes accelerating into trill, as well as slightly ascending series of tripled notes, "tididit, tididit, tididit". Call a high-pitched, sharp, penetrating "pyeek" or "kick", sometimes in series.

**Habitat.** *Páramo* grassland and elfin forest; dense undergrowth in timber-line ecotone and edge of humid cloudforest, often mixed with grass and ferns; also locally in *Polylepis* woodland. Mainly 2800-4000 m, locally down to 2300 m.

**Food and Feeding.** Mostly arthropods, but small seeds also recorded in diet. Forages singly or in pairs, rarely in mixed-species flocks. Gleans items from foliage and small branches in understorey, with occasional acrobatic manoeuvres.

**Breeding.** Presumably monogamous. Nest a ball of moss, grass and plant down, placed near ground in grass. Clutch 2 eggs. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally fairly common in appropriate habitat. Linear nature of its habitat means that total population likely to be rather small; also, timber-line habitats have been greatly altered and reduced by fire and grazing throughout most of the Andes.

**Bibliography.** Borrero (1960), Carriker (1933), Chapman (1926), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Graves (1985), Hilty (2003a), Hilty & Brown (1986), O'Neill & Parker (1976), Olivares (1969), Parker *et al.* (1982), Pfeifer *et al.* (2001), Remsen (1984b, 2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgely *et al.* (1998), Rodner *et al.* (2000), Salaman (1994), Stotz *et al.* (1996), Vaurie *et al.* (1972), Vuilleumier (1969), Vuilleumier & Ewert (1978).

## 62. Mouse-coloured Thistletail

### *Schizoeaca griseomurina*

**French:** Synallaxe souris **German:** Olivrücken-Distelschwanz **Spanish:** Piscuiz Ratón

**Taxonomy.** *Synallaxis griseo-murina* P. L. Sclater, 1882, San Lucas, Loja, Ecuador.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within individual species-level taxa in Furnariidae. Present species is almost certainly paraphyletic with regard to *S. fuliginosa* (which brackets its distribution to N and S); probably closest to latter's nominate race, sharing with it the feature of a white eyering. Monotypic.

**Distribution.** Andes of S Ecuador (S from Azuay and Morona-Santiago) and N Peru (Piura, Cajamarca).

**Descriptive notes.** 18-20 cm; 16-20 g. Relatively dark thistletail. Has brownish face with conspicuous white eyering, pale line behind eye; crown and entire upperparts, including wings and tail, uniform dark greyish-brown to olive-brown; tail long, strongly graduated, deeply forked, barbs reduced in density and length distally, giving ragged, pointed appearance; chin greyish-white, blending to greyish throat and breast and to paler grey belly, flanks tinged brownish; iris brown; upper mandible blackish to dark grey, lower mandible paler grey to blue-grey, sometimes with blackish tip; tarsus and toes grey to blue-grey. Sexes alike.

Juvenile undescribed. **Voice.** Song described as ascending series of "sweetee" notes accelerating into trill, c. 2 seconds long, given at 6-second intervals; call a sharp "peent" and high-pitched, descending "pseeew".

**Habitat.** *Páramo* grassland; inhabits dense undergrowth in timber-line ecotone, edge of humid cloudforest, often mixed with grass and ferns, and *Polylepis* woodland. Mostly 2800-4000 m, locally down to 2500 m; isolated population at 2150 m in N Peru (R Comainas drainage).

**Food and Feeding.** Arthropods. Forages singly or in pairs, rarely in mixed-species flocks. Gleans food items from foliage and small branches in understorey, usually within 1 m of ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Central Andean *Páramo* EBA. Fairly common to uncommon in suitable habitat. Total population rather small owing to relatively small area of distribution and linear nature of its habitat. Occurs in Las Cajas National Recreation Area, in Ecuador. Burning and grazing of timber-line habitats have greatly reduced extent of areas suitable for occupation by this species.

**Bibliography.** Chapman (1926), Cory & Hellmayr (1925), Fjeldså & Krabbe (1986, 1990), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Awbrey (1997a), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 63. Eye-ringed Thistletail

### *Schizoeaca palpebralis*

**French:** Synallaxe à lunettes **German:** Brillen-Distelschwanz **Spanish:** Piscuiz de Anteojos  
**Other common names:** Rufous-chinned Thistletail

**Taxonomy.** *Schizoeaca palpebralis* Cabanis, 1873, Maraynioc, Junin, Peru.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Monotypic.

**Distribution.** Andes of C Peru (Junin).

**Descriptive notes.** 18-20 cm; 16-18 g. Typical thistletail. Conspicuous broad white eyering stands out on chestnut-brown face with darker brown lores; crown and upperparts, including wings, dark chestnut-brown; tail long, strongly graduated, deeply forked, barbs reduced in density and length distally, looks ragged and pointed, slightly brighter and more rufescent than back; chin ochre-rufous, throat and underparts greyish, becoming paler on belly, flanks tinged brownish; iris grey to light brown to chestnut; upper mandible black, lower mandible black or grey; tarsus and toes grey to blue-grey. Sexes alike. Juvenile lacks chestnut on chin, has browner flanks and paler belly. **Voice.** No information available.

**Habitat.** *Páramo* grassland; inhabits dense undergrowth in timber-line ecotone, at edge of humid cloudforest, often mixed with grass and ferns; 3050-3300 m, occasionally lower.

**Food and Feeding.** Poorly known. Forages in understorey, singly or in pairs, but single-species flocks of up to 15 reported. Presumed to glean arthropods from foliage and branches.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in North-east Peruvian Cordilleras EBA. Fairly common in appropriate habitat, but linear nature of this, coupled with its tiny range, means that total population is rather small. Burning and grazing of timber-line habitats in Andes have greatly reduced total surface extent of habitat.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Parker *et al.* (1982), Peters & Griswold (1943), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 64. Vilcabamba Thistletail

### *Schizoeaca vilcabambae*

**French:** Synallaxe de Vilcabamba **German:** Rostkehl-Distelschwanz **Spanish:** Piscuiz de Vilcabamba  
**Other common names:** Ayacucho Thistletail (*ayacuchensis*)

**Taxonomy.** *Schizoeaca vilcabambae* Vaurie *et al.*, 1972, Cordillera Vilcabamba, 3190 m, Cuzco, Peru.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Distinctive race *ayacuchensis* may merit full species rank; difference in plumage between it and nominate as great as that between *S. helleri* and *S. harterti*. Two subspecies currently recognized.

**Subspecies and Distribution**

*S. v. ayacuchensis* Vaurie *et al.*, 1972 - Andes of S Peru (N Ayacucho).

*S. v. vilcabambae* Vaurie *et al.*, 1972 - Vilcabamba Mts, in S Peru.

**Descriptive notes.** 18-19 cm; 18-19 g. Typical thistletail. Nominative race has ill-defined supercilium behind eye slightly paler than brownish face; crown and upperparts dull dark greyish-brown, crown feathers with slightly darker centres giving faintly spotted appearance; wings like back, edged rufous; tail long, strongly graduated, deeply forked, barbs reduced in density and length distally, looks ragged and pointed, paler and more rufescent than back; chin light ochraceous, throat and underparts greyish, many feathers with darker centres giving faintly scaled appearance, flanks tinged brownish; iris brown to greyish-brown; tarsus and toes grey. Sexes alike.

Juvenile undescribed. Race *ayacuchensis* has blacker face, greatly reduced supercilium, much darker, chestnut chin, slightly darker and more uniform underparts. **Voice.** Undescribed.

**Habitat.** *Páramo* grassland, elfin forest and *Polylepis* woodland; dense undergrowth in timber-line ecotone, and edge of humid cloudforest, often mixed with grass and ferns; 2830-3600 m, rarely down to 2500 m.

**Food and Feeding.** Little known. Feeds solitarily or in pairs in understorey; probably gleans arthropods from foliage and branches.

**Breeding.** No information.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in North-east Peruvian Cordilleras EBA. Fairly common in appropriate habitat. Because of its tiny range and the linear nature of its habitat, total population is likely to be rather small.

**Bibliography.** Alonso *et al.* (2001), Anon. (2003e), Fjeldså & Krabbe (1990), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vaurie *et al.* (1972), Weske (1972).

## 65. Puna Thistletail

### *Schizoeaca helleri*

**French:** Synallaxe de Heller **German:** Punadistelschwanz **Spanish:** Piscuiz de la Puna  
**Other common names:** Heller's Thistletail

**Taxonomy.** *Schizoeaca helleri* Chapman, 1923, Cedrobamba, 12,000 feet [c. 3660 m], Cuzco, Peru. Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Birds from S Puno (Peru), with darker plumage and probably significantly smaller body size, appear to represent an undescribed taxon. Monotypic.

**Distribution.** Andes of S Peru (Cuzco, Puno) and N Bolivia (extreme N La Paz).

**Descriptive notes.** 17-18 cm; 13-16 g. Typical thistletail. Has vague greyish supercilium behind eye, brownish-grey face; crown dark rufescent brown, forehead greyer and faintly mottled; upperparts, including wings, dull dark rufescent brown; tail long, strongly graduated and deeply forked, barbs reduced in density and length distally, giving ragged and pointed appearance, paler and more rufescent than back; back and tail darker, less reddish, in Puno (Peru); chin light ochraceous, bordered below by dark greyish upper throat with paler shaft streaks; underparts greyish, tinged brownish on flanks and undertail-coverts (breast slightly darker in

Puno); iris brownish-grey to pale tan; upper mandible black to grey, lower mandible grey to whitish with blackish tip; tarsus and toes grey to blue-grey. Distinguished from very similar *S. harterti* by slightly darker upperparts, slightly brighter underparts, greyer face. Sexes alike. Juvenile undescribed.

**Voice.** Song a series of sputtering notes, increasing in volume and then fading at end, "pee-pee-p-p-t-t-t-t", 1.5-2 seconds long; call an emphatic "peent" or "feet", very similar to that of *S. griseomurina*.

**Habitat.** *Páramo* grassland and elfin forest; inhabits dense undergrowth in timber-line ecotone, at humid cloudforest edge, often mixed with grass and ferns; 2800-3600 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs. Gleans prey from foliage and branches in understorey.

**Breeding.** No information. Presumably monogamous.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA. Uncommon to fairly common. Total population rather small, as appropriate habitat is linear in nature. Occurs in Machu Picchu Historical Sanctuary, in Peru. Burning and grazing of timber-line habitats in Andes have severely reduced the extent of suitable areas for occupation by this species.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Parker & O'Neill (1980), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Walker (2001).

## 66. Black-throated Thistletail

### *Schizoeaca harterti*

**French:** Synallaxe à gorge noire **German:** Schwarzkehl-Distelschwanz **Spanish:** Piscuiz Gorginegro  
**Other common names:** Hartert's Thistletail

**Taxonomy.** *Schizoeaca harterti* Berlepsch, 1901, Unduavi (Hichuloma), La Paz, Bolivia.

Forms a superspecies with other members of genus, as a series of non-overlapping mountain-top replacements, and all sometimes considered conspecific; their vocalizations seem fairly close, but plumage patterns differ to an extent not found within species-level taxa in the Furnariidae. Two subspecies recognized.

**Subspecies and Distribution**

*S. h. harterti* Berlepsch, 1901 - Andes of N Bolivia (La Paz).

*S. h. hejarianoi* Remsen, 1981 - Andes of C Bolivia (Cochabamba).

to grey. Differs from very similar *S. helleri* in slightly paler upperparts, slightly duller underparts, browner face. Sexes alike. Juvenile undescribed. Race *bejaranoi* is more ochraceous, particularly on auriculars, malar region and neck side, paler and more ochraceous forehead, usually paler, less blackish loreal area, paler grey underparts with ochraceous sides and flanks. VOICE. Song a series of emphatic squeaky notes, accelerating and then slowing, descending slightly at end, lasts 1-1.5 seconds; rodent-like "pseea" as alarm.

**Habitat.** *Páramo* grassland and elfin forest; dense undergrowth in timber-line ecotone, and edge of humid cloudforest, often mixed with grass and ferns; 2900-3400 m.

**Food and Feeding.** Mostly arthropods. Of 19 stomachs examined, all contained arthropod remains and two also contained a few seeds 1-2 mm in diameter. Forages singly or in pairs, mostly in understorey, but in bush-tops at forest edge; mean foraging height in La Paz was 1.4 m above ground and 1.9 m below top of canopy. Gleans arthropods from foliage, mainly upper surfaces of green leaves, and small branches, occasionally from mosses, grasses and rocks.

**Breeding.** Nestlings in Jan. Presumably monogamous. One nest described, an oval mass 20 x 15 cm, mainly of moss and some twigs, side entrance, chamber lined with wet moss, placed on top of clump of grass next to a shrub. Clutch probably 2 eggs; both sexes feed nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA. Fairly common to common. Linear nature of range means that total population is rather small. Burning and grazing of timber-line habitats has greatly reduced the extent of appropriate habitat for this species.

**Bibliography.** Cory & Hellmayr (1925), Ejlsd & Krabbe (1990), Kessler & Herzog (1998), Remsen (1981, 1985, 2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1969).

Genus *OREOPHYLAX* Hellmayr, 1925

67. Itatiaia Spinetail

*Oreophylax moreirae*

**French:** Synallaxe de l'Itatiaia **German:** Blasser Distelschwanz **Spanish:** Piscuiz de Itatiaia  
**Other common names:** Itatiaia/Brazilian Thistletail, Brazilian Spinetail

**Taxonomy.** *Synallaxis moreirae* Miranda-Ribeiro, 1906, Monte Redondo and Retiro de Ramas, Serra do Itatiaia, Rio de Janeiro, Brazil.

Relationships uncertain; retained in monotypic genus pending further research. Included within genus *Schizoeaca* by some authors, and has similar morphology and plumage, as well as nest; differs morphologically, however, most notably in length and shape of rectrices (webs broader, barbs not quite so reduced distally, tail less forked) and slightly thinner bill; also, *Schizoeaca*, with its narrow elevational and ecological distribution in high Andes, would seem unlikely to have a member (or even a close relative) in SE Brazil. Others consider voice and general behaviour to be more like those of more widely distributed *Asthenes*, which does, moreover, have a representative in SE Brazil. Monotypic.

**Distribution.** Mountains of SE Brazil: Serra do Caraça, Serra do Itatiaia, Serra do Caparaó and Serra dos Órgãos (Minas Gerais, NE São Paulo, Rio de Janeiro, S Espírito Santo).

also described as descending "dew-dee-dee-dee-déééééééééé"; high-pitched "psee, trtrtr, berrrit" also given.

**Habitat.** Semi-humid/humid montane scrub; thickets of bamboo (*Chusquea pinifolia*), overgrown clearings, and tall grass near scrub; generally above timber-line, 1850-2800 m.

**Food and Feeding.** Arthropods; fruits (drupes of *Rapanea*) also occasionally eaten. Usually forages in pairs, or in groups of three, at low levels. Gleans prey items from foliage and branches, often with acrobatic manoeuvres.

**Breeding.** Presumably monogamous. Nest an oval mass of moss, some twigs incorporated around outside, entrance hole high near top and slightly to one side. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Uncommon to locally fairly common, but range is very small. Common in Itatiaia National Park and reasonably common in Serra dos Órgãos National Park; common on the highest peaks of Serra do Caraça. Burning of timber-line ecotone vegetation a major threat.

**Descriptive notes.** 17-18 cm; 12-14 g. Typical thistletail. Nominative race has vague light brown supercilium behind eye, rufous-brown face; crown and upperparts, including wings and tail, dark rufescent brown, slightly redder on forehead; tail long, strongly graduated, deeply forked, barbs reduced in density and length distally, appears ragged and pointed; chin greyish-white, throat black with whitish shaft streaks, underparts brownish-grey, browner on flanks and undertail-coverts; iris light brown to brown; upper mandible blackish to dark grey, lower mandible grey to pinkish-grey with dark tip; tarsus and toes blue-grey

**Bibliography.** Anon. (2003c), Cordeiro (2001), Cory & Hellmayr (1925), Ferreira de Vasconcelos & Melo-Júnior (2001), Holt (1928), Melo-Júnior *et al.* (1997, 1998), Parker & Goerck (1997), Pineschi (1990), Pinto (1978), Ridgely & Tudor (1994), dos Santos (2000), Scott & Brooke (1985), Sick (1970, 1985d, 1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Willis & Oniki (1993).

Genus *SCHOENIOPHYLAX* Ridgway, 1909

68. Chotoy Spinetail

*Schoeniophylax phryganophilus*

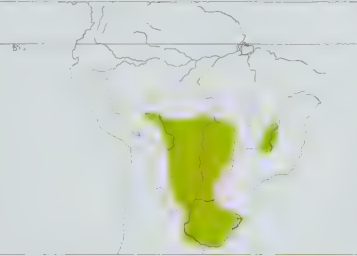

**French:** Synallaxe damier **German:** Weißwangen-Dickichtschlüpfer **Spanish:** Pijui Chotoy

**Taxonomy.** *Sylvia phryganophila* Vieillot, 1817, Paraguay. Similarities in general morphology and nest structure have led some authors to place this species in *Synallaxis*, but it differs strongly from all members of that genus in voice and plumage pattern. Isolated race *petersi* evidently differs only in being smaller, but this requires re-evaluation with modern techniques of analysis. Two subspecies recognized.

**Subspecies and Distribution.**

*S. p. phryganophilus* (Vieillot, 1817) - E Bolivia (Beni, Santa Cruz, Tarija), S Brazil (Mato Grosso do Sul, S Rio Grande do Sul), Paraguay (except extreme E), NE Argentina (S to Santiago del Estero, Santa Fe and N Buenos Aires) and Uruguay.

*S. p. petersi* Pinto, 1949 - E Brazil (N Minas Gerais, W Bahia).

**Descriptive notes.** 20-21 cm; 15-22 g. Large spinetail with distinctive throat pattern unlike that of any other furnariid. Has white supercilium becoming duller posteriorly, light brown auriculars faintly streaked; forehead dark brown, blending to chestnut crown with inconspicuous dark brown streaks, brown hindcrown with faint dark brown streaks; back sandy brown with conspicuous darker brown streaks, lower back to undertail-coverts light brown; wings mostly light brown, conspicuous chestnut shoulder; tail long, strongly graduated, light brown, shafts blackish; chin and upper throat bright yellow, sharply defined black

square in centre of lower throat, bordered laterally by white; upper breast apricot, blending to buffy white lower breast and whitish belly, ill-defined dull buff or brownish-buff sides and flanks, undertail-coverts more rufescent; iris red to brown (source of variation unknown); upper mandible blackish to dark grey, lower mandible grey to bluish, sometimes dark tip; tarsus and toes light grey to brownish. Sexes alike. Juvenile has brown crown, less sharply defined streaking on upperparts, whitish chin, indistinct black throat patch, broader and rounder-tipped rectrices. Race *petersi* is like nominate but smaller. Voice. Song a distinctive series of low-pitched "cho" notes (sounding as if made by a larger bird), accelerating towards end.

**Habitat.** Riparian thickets and second-growth scrub; open areas with scattered trees and shrubs, edges of marshes, gallery woodland, *monte* woodland. From near sea-level to 500 m.

**Food and Feeding.** Arthropods; reported items are Coleoptera. Forages singly or in pairs. Gleans items from foliage and small branches, usually within 1 m of ground.

**Breeding.** Season during austral spring-summer; nests from late Sept, eggs in Oct-Jan and nestlings in Nov-Jan in Argentina. Presumably monogamous. Nest-building seems to occur throughout year; nest a large ball c. 25-60 cm in diameter, of sticks, often or usually thorny ones, horizontal or upward-slanting side entrance tube 25-60 cm long, sometimes curved, and lined with soft plant material, inner chamber sometimes (perhaps often) with oval cup 10-19 cm in diameter made from soft plant fibres or cotton and some green leaves or rootlets; placed 0.7-3.5 m, rarely to 17 m, above ground in bush or small tree or, perhaps especially, in palm, often isolated, sometimes on top of old nest; chamber in communal nest of Monk Parakeets (*Myiopsitta monachus*) occasionally used. Clutch 4-5 eggs, rarely 3 or 6; incubation period c. 15-16 days; nestling period 13-14 days. Nests regularly parasitized by Striped Cuckoo (*Tapera naevia*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in most of its range. Seems to be fairly adaptable, occurring in secondary habitats and scrub.

**Bibliography.** Anon. (2003d), Aramburú (1990), Brooks (1997), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1979d), Cory & Hellmayr (1925), Cuervo (1985), Hayes (1995), Mason (1985), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Naumburg (1930), Navas & Bö (1988), de la Peña (1987, 1988, 1995), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Wetmore (1926), Willis (1992b), Willis & Oniki (1990, 1991), Zotta (1940).

Genus *SYNALLAXIS* Vieillot, 1818

69. Rufous-capped Spinetail

*Synallaxis ruficapilla*

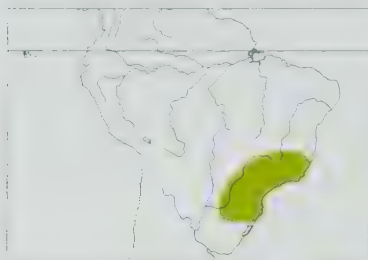

**French:** Synallaxe à calotte rousse **Spanish:** Pijui Coronirrojo  
**German:** Rotkappen-Dickichtschlüpfer

**Taxonomy.** *Synallaxis ruficapilla* Vieillot, 1819, near Rio de Janeiro, Brazil.

Forms a superspecies with *S. cinerea* and *S. infusca*, this superspecies suggested by some authors as being most closely related to *S. frontalis*, *S. azarae* and *S. coursini* on basis of plumage and vocal similarities. Formerly considered to include *S. infusca* as a race, but vocal differences indicate that latter merits rank of full species. Monotypic.

**Distribution.** SE Brazil (S Goiás, S Minas Gerais and Espírito Santo S to N Rio Grande do Sul), E Paraguay (Canendiyu, Alto Paraná, Itapúa) and NE Argentina (Misiones, Corrientes).

**Descriptive notes.** 13-17 cm; 12-16 g. Typical *Synallaxis* with contrasting crown and wings. Has broad buff supercilium contrasting strongly with dark brownish-grey lores and auriculars; crown and hindneck bright orange-rufous, forehead slightly paler, sharply contrasting with rufescent brown back and uppertail-coverts; wings mostly chestnut-brown; tail strongly graduated, 8 rectrices, pointed, distal 1 cm somewhat disintegrated, chestnut; tiny chin spot tawny, rest of chin and throat whitish with indistinct grey streaking; upper breast greyish, blending to paler buffy brownish on breast, belly, sides and flanks, palest in centre of belly; iris reddish-brown; upper mandible black, lower mandible grey with dark tip; tarsus and toes greenish-grey. Differs from very similar *S. cinerea* mainly in browner, less grey, underparts, Sexes alike. Juvenile has much duller crown, weakly defined throat patch, underparts variably washed ochraceous or brownish. **Voice.** Song a fast nasal "di-di-di-réé", number of "di" notes variable, often repeated for long periods, often between pair-members; scold a distinctive low-pitched trill, "tshrrr".

**Habitat.** Montane evergreen forest, tropical lowland evergreen forest, secondary forest; inhabits forest undergrowth and edge, and second-growth woodland, usually in *Chusquea* bamboo thickets and perhaps restricted to them in many areas; more of a true forest species than are most congeners. From near sea-level to 1400 m.

**Food and Feeding.** Little known; food presumably arthropods. Usually seen in pairs, often in mixed-species flocks. Forages mainly in understorey, occasionally in mid-storey and down to ground. Prey presumably gleaned from foliage and small branches, mainly within 1-2 m of ground.

**Breeding.** Season during austral spring-summer. Presumably monogamous. Nest 25-40 cm long, a mass of sticks (some up to 15 cm long), usually thorny, total weight up to 4.2 kg, side entrance tube, or entrance hole on top, tunnel leading downwards to nest-chamber; placed 1-2.5 m above ground among interlocking branches in dense vegetation. Clutch 2-3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to common. Relatively poorly known species. Occurs in Itatiaia and Serra dos Órgãos National Parks, Serra do Mar State Park, and Augusto Ruschi Biological Reserve, in Brazil; also in Iguazú National Park and Uruguá-i Provincial Park, in Argentina.

**Bibliography.** Aleixo (1997), Aleixo & Galetti (1997), dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Anon. (2000d, 2003d), Avanzo & Sanfilippo (2000), Belton (1984), Brooks *et al.* (1993), Cândido (2000), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1979d, 1980d), Cordeiro (2001), Cory & Hellmayr (1925), Ferreira de Vasconcelos & Melo-Júnior (2001), Fraga & Narosky (1985), Goerck (1999a), Hayes (1995), Hayes & Scharf (1995a), Madroño, Robbins & Zyskowski (1997), Marini, Motta-Júnior *et al.* (1997), Mazar Barnett & Pearnan (2001), Melo-Júnior *et al.* (2001), Narosky *et al.* (1983), Navas & Bö (1988), Olrog (1963a), Pacheco & Gonzaga (1995), Parker & Goerck (1997), de la Peña (1988), Pinto (1950, 1978), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Silveira (1998), Simon, Pacheco & Silva (1999), Stotz *et al.* (1996).

## 70. Bahia Spinetail

### *Synallaxis cinerea*

**French:** Synallaxe du Bahia **German:** Bahiadickichtschlüpfer **Spanish:** Pijui de Bahía

**Taxonomy.** *Synallaxis cinereus* Wied, 1831, "Capitao Filisberto road," southern Bahia, Brazil. Scientific name was long considered a junior synonym of *S. ruficapilla*, but recently shown to represent a separate species; *S. whitneyi* is a synonym. Forms a superspecies with *S. ruficapilla* and *S. infusata*; this superspecies is suggested by some authors as being most closely related to *S. frontalis*, *S. azarae* and *S. courseni* on basis of plumage and vocal similarities. Monotypic.

**Distribution.** E Brazil (S Bahia, NE Minas Gerais).

**Descriptive notes.** 15-17 cm; 16-21 g. Has broad cinnamon-buff supercilium contrasting with brownish-grey lores and auriculars; crown and hindneck bright orange-rufous, forehead slightly paler, contrasting rufescent brown back and uppertail-coverts; wings mostly chestnut-brown; tail strongly graduated, 8 rectrices, pointed, distal 1 cm somewhat disintegrated, chestnut; tiny chin spot tawny, rest of chin and throat whitish-grey with indistinct grey streaking, underparts dark greyish; iris reddish-brown to dark brown; bill dark grey, sometimes paler grey base; tarsus and toes olivaceous to dark grey. Distinguished from very similar *S. ruficapilla* mainly by dark greyish, rather than light brown, underparts. Sexes alike. Juvenile undescribed. **Voice.** Song a double-noted "di-réé, di-réé", constantly repeated by members of pair; scold a spitting trill, similar in quality to that of *S. ruficapilla* but shorter; contact call a sharp, loud note, like first note of scold.

**Habitat.** Montane evergreen forest; in undergrowth of humid forest, especially dense areas of vines, ferns and bamboo near edge; 500-1000 m.

**Food and Feeding.** Arthropods. Three stomachs contained two species of flat-bug (Aradidae), three species of ant, five of Coleoptera (including Aedeagidae larvae, and Curculionidae), oothecae of orthopterans, and a small millipede (Diplopoda). Usually forages in pairs. Prey obtained by gleaning and probing dead leaves, stems and small branches, mostly within 1-2 m of ground, occasionally almost on ground and as high as 5 m up.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in Atlantic Forest Mountains EBA. Fairly common to common, but declining as a result of habitat destruction. Known only from fragments of the vanishing humid Atlantic Forest of the mountains of S and interior Bahia (Serra de Ouricana, Serra das Lontras/Javi, Serra Bonita, Chapada Diamantina), and NE Minas Gerais (near Almenara). Total population estimated at 1000-2499 individuals. Most of the remaining habitat fragments are subjected to degradation by cattle grazing and colonization projects; population in Minas Gerais is threatened by a land-reform colonization project. Present in Chapada Diamantina National Park, but this park is not adequately protected.

**Bibliography.** Cordeiro (2001), Gonzaga & Pacheco (1995), Gonzaga *et al.* (1995), Pacheco & Gonzaga (1995), Parrini *et al.* (1999), Ribon *et al.* (2002), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Whitney & Pacheco (2001).

## 71. Pinto's Spinetail

### *Synallaxis infusata*

**French:** Synallaxe de Pinto **German:** Dunkelbauch-Dickichtschlüpfer **Spanish:** Pijui de Pinto  
**Other common names:** Plain/Alagoas/Pernambuco Spinetail

**Taxonomy.** *Synallaxis ruficapilla infusata* Pinto, 1950, Usina Nossa Senhora do Carmo, Vitória de Santa Antão, eastern Pernambuco, Brazil.

Forms a superspecies with *S. ruficapilla* and *S. cinerea*, this superspecies suggested by some authors as being most closely related to *S. frontalis*, *S. azarae* and *S. courseni* on basis of plumage and vocal similarities. Was previously considered a race of *S. ruficapilla*, but vocal differences indicate that it merits rank of full species. Some authors have proposed that it is more closely related to *S. brachyura* or *S. hypospodia*. Monotypic.

**Distribution.** NE Brazil (E Alagoas, E Pernambuco).

**Descriptive notes.** 16-18 cm; 16-20 g. Has reddish-chestnut forehead and crown, brownish-grey back, extensively rufous wings; tail strongly graduated, 10 rectrices stiff with sharply pointed tips, distal 1 cm somewhat disintegrated, dark rufous-chestnut; black chin spot, throat diffusely streaked grey and whitish; underparts uniform dark slaty grey, sometimes paler in centre of belly; iris dark brownish; bill dark grey; tarsus and toes greyish or greenish-grey. Distinguished from similar *S. ruficapilla* by darker and greyer back, more intensely rufous upperwing-coverts and tail, darker and more uniform greyish underparts, supercilium much reduced or absent. Sexes alike. Juvenile undescribed. **Voice.** Song "reet, reet", similar in quality to those of *S. ruficapilla* and *S. cinerea*, repeated 1-3 times (typically twice); scold a spitting trill, virtually identical to that of *S. cinerea*; also gives trill lasting about 1 minute, unlike any vocalization of congeners.

**Habitat.** Tropical lowland evergreen forest; woodland edge, scrubby forest, early second growth, commonly in dense undergrowth; to 500 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs. Gleans prey items from foliage, dead leaves and small branches, within 1-2 m of ground.

**Breeding.** Nest sited on tangle of branches or in fork of tree, amongst bromeliads, usually well covered by lianas; usually 1-5 m up, exceptionally 7 m up or on ground. Nest is a voluminous globular structure 25-30 cm wide, c. 40 cm deep, made of dry sticks, dry leaves, bits of bark and some snake skins; lateral tunnel-like entrance 25-35 cm long; nesting chamber 10-12 cm wide, lined with green grass matted together with cobwebs; some leaves added to outside during incubation; overall weight of 9 nests 500-1200 g; nest-building takes 20-40 days, up to 60 days. Old nest sometimes refurbished, or material used for new one; new nests may be built near old ones year after year. Clutch 2 eggs; incubation 21-22 days; nestlings have sparse grey down; fed insects at intervals of 5-20 minutes (at 7 days old); nestling period 14-16 days. Both adults share duties of nest-building, incubation, feeding young and removing faecal sacs.

**Movements.** Resident.

**Status and Conservation.** **CRITICAL.** Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Uncommon to fairly common, but has tiny range of less than 80 km<sup>2</sup>; in Alagoas, fairly common in forest clearings and at edges of dense forest. Total population estimated at 1000-2500 individuals; declining as a result of rapid deforestation in the region. Present in Pedra Talhada State Park, Salto do Biological Reserve, and Serra dos Cavalos UFPE Ecological Station. **Bibliography.** Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cordeiro (2001), Goerck (2002), Olmos (1993), Oren (1991), Pacheco & Gonzaga (1995), Pinto (1950, 1954a, 1978), Ridgely & Tudor (1994), Sick (1985c, 1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Studer (2003), Teixeira *et al.* (1987), Wege & Long (1995).

## 72. Grey-bellied Spinetail

### *Synallaxis cinerascens*

**French:** Synallaxe grisín **German:** Graubauch-Dickichtschlüpfer **Spanish:** Pijui Ceniciento

**Taxonomy.** *Synallaxis cinerascens* Temminck, 1823, Ypanema, São Paulo, Brazil.

No close relatives have been proposed. Monotypic.

**Distribution.** SE Brazil (S from S Goiás, S Minas Gerais and S Espírito Santo), E Paraguay (E from Paraguari), NE Argentina (Misiones, E Corrientes) and N Uruguay.

**Descriptive notes.** 14-15 cm; 10-14 g. Has grey-brown face with indistinct pale greyish supraloral spots, blackish lores, hint of grey postocular stripe; forehead dark greyish-brown, blending to dark brownish-olive crown and to richer brown back and uppertail-coverts; wings mostly rich reddish-chestnut; tail graduated, 10 rectrices, these narrowing at tips to virtually nothing but the shaft (thus producing "spiny" appearance), dark chestnut; chin whitish, upper throat mottled black and pale grey, lower throat black, contrasting strongly with brownish-grey breast, becoming greyer and paler in centre of belly and browner on

flanks and undertail-coverts; iris reddish-brown; bill black, often grey base of lower mandible; tarsus and toes greenish-grey. Sexes alike. Juvenile has less distinct throat patch, faintly mottled and slightly paler underparts. **Voice.** Most frequent vocalization a shrill "wheet-beet", "wheet, bu-beeyt" or "seeee, pu-tee", intervals between vocalizations evidently longer than is the case with many of its relatives.

**Habitat.** Tropical lowland evergreen forest and montane evergreen forest; inhabits dense undergrowth of humid forest and tall second growth; not an "edge" species. Occurs up to 1150 m.

**Food and Feeding.** Arthropods; Orthoptera (Tettigoniidae) and Coleoptera recorded as taken. Forages usually in pairs, from ground to understorey. Prey items gleaned mostly from leaf litter, also from undergrowth vegetation within 1-2 m of ground.

**Breeding.** Season probably during austral spring-summer; nestlings in Nov. Presumably monogamous. Nest is a large mass 0.5-0.6 m in total length, weighing 3.7-3.9 kg, of tightly interwoven sticks mostly 12-22 cm long, some weighing as much as 13 g, external tubular entrance tunnel c. 0.2-0.3 m long, sloping upwards from nest-chamber to an upward-facing entrance hole, area above nest-chamber thatched with bark and leaves, floor with pad of soft, fresh leaves; placed on slightly scraped-out bowl on ground and, if on slope, supported by sticks acting as pillars (unknown if these were placed there by the birds). Clutch 3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in most of range. In Brazil, uncommon in Serra da Canastra, Iguaçu and Aparados da Serra National Parks

and rare in Itatiaia National Park; present also in Matas dos Godoy State Park. In Paraguay, uncommon in Caaguazú, Cerro Corá and Ybicui National Parks, and present in San Rafael National Park. Also present in Iguazú National Park and Uruguá-I Provincial Park, in Argentina. Extensive deforestation within this species' relatively small range has dramatically reduced its habitat. Its dependence on forest makes it more vulnerable to deforestation than are many other members of genus.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Anon. (2000e, 2003d), Belton (1984), Bornschein & Reinert (1997a), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1980d), Cory & Hellmayr (1925), Cuello (1985), Ferreira de Vasconcelos & Melo-Júnior (2001), Fraga & Narosky (1985), Goerck (1999a), Hayes (1995), Hayes & Scharf (1995a, 1995b), Madroño, Robbins & Zyskowski (1997), Mazar Barnett & Pearman (2001), Navas & Bó (1988), Olrog (1963a), Parker & Goerck (1997), de la Peña (1988), Pinto (1978), Ridgely & Tudor (1994), Schubart *et al.* (1965), Scott & Brooke (1985), Sick (1993, 1997), Silveira (1998), Simon & Pacheco (1996), Stotz *et al.* (1996), Whitney & Pacheco (1994), Zotta (1938).

PLATE 17

## 73. Silvery-throated Spinetail

### *Synallaxis subpudica*

**French:** Synallaxe à gorge argentée

**Spanish:** Pijui de Cundinamarca

**German:** Grauschwanz-Dickichtschlüpfer

**Taxonomy.** *Synallaxis subpudica* P. L. Selater, 1874, "Bogotá".

Thought by some to be possibly related to *S. azarae* and *S. courseni* on account of distribution and superficial plumage similarity, but voice is very different. Vocal similarities have suggested to others that it is closest to the superspecies formed by *S. macconnelli*, *S. moesta* and *S. cabanisi*. Monotypic.

**Distribution.** E Andes of Colombia (N Boyacá, Cundinamarca).

**Descriptive notes.** 17-18 cm. Has greyish-brown face, thin light cinnamon supercilium behind eye; forehead greyish-brown, hind-crown and hindneck rufous-chestnut, back and uppertail-coverts brown; chestnut wing-coverts, slightly paler bases of remiges contrasting with brown distal portions; tail very long, strongly graduated, 10 rectrices, slightly disintegrated towards pointed tips, slightly darker than back; throat grey, some darker feather centres in centre of throat producing faintly mottled appearance, blackish centre of lower throat partly concealed by greyish feather margins; underparts dull olive-tinged greyish-brown, belly paler; iris dark reddish-brown; upper mandible blackish-grey, lower mandible grey; tarsus and toes grey. Sexes alike. Juvenile lacks chestnut on crown. Voice. Song a fast, accelerating, descending and fading series of chattering notes with "laughing" tone, "chi-chi-chi-che-che-chu-chu-chu", evidently often as duet. Call a sharp "kik", sometimes repeated several times; alarm a low trill.

**Habitat.** Montane evergreen forest edge, secondary forest edge, second-growth scrub; dense undergrowth at edge of humid cloudforest, second growth, and regenerating clearings; mainly 2100-3200 m.

**Food and Feeding.** Little known. Usually in pairs; presumably gleans arthropods from foliage and small branches, within 1-2 m of ground.

**Breeding.** Nest a large globular mass of sticks c. 50-60 cm high, 30-40 cm in diameter, side entrance with long tube to nest-chamber, latter lined with moss and twigs, usually placed c. 2 m up in bush. One clutch reported as containing 1 egg. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Colombian East Andes EBA. Fairly common to common within small range. Tolerates fair degree of anthropogenic habitat disturbance, and probably benefits from fragmentation of forest.

**Bibliography.** Cory & Hellmayr (1925), Fjeldsa & Krabbe (1990), Hilty & Brown (1986), Olivares (1969), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 74. Sooty-fronted Spinetail

### *Synallaxis frontalis*

**French:** Synallaxe à front sombre

**Spanish:** Pijui Frentigris

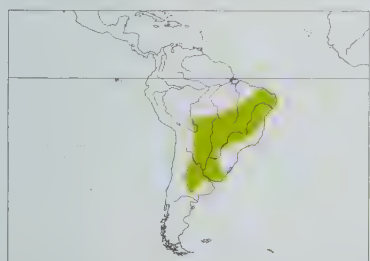

**German:** Graustirn-Dickichtschlüpfer

**Other common names:** Pelzel's Spinetail; Grey-browed Spinetail ("S. *poliophrys*")

**Taxonomy.** *Synallaxis frontalis* Pelzel, 1859, Rio São Francisco, Bahia, Brazil.

Considered by some authors to form a superspecies with *S. azarae* and *S. courseni* on basis of plumage and vocal similarities. Proposed taxon *S. poliophrys* was based on a misidentified specimen of present species. Plumage varies clinally, being brightest in NE and duller in SW; traditionally recognized race *fuscipennis*, described from Bolivia, almost certainly based on this subtle clinal variation, as none of its alleged characters (broader and greyer frontal band, duller back, brown inner webs of central rectrices) allows diagnosis of individual specimens, even when comparing extremes from foothills of Bolivian Andes with distant populations from NE Argentina. Population of R Cotacajes, in Cochabamba (Bolivia), apparently represents an undescribed race. Monotypic.

**Distribution.** E, S & SE Brazil (Maranhão E to Rio Grande do Norte, and S to Mato Grosso do Sul and N São Paulo, also S Rio Grande do Sul), E Bolivia (Cochabamba S to Tarija and Santa Cruz), N Argentina (S to Mendoza, La Pampa and N Buenos Aires), Paraguay (except SE) and Uruguay.

**Descriptive notes.** 14-16 cm; 11-17 g. Has brownish-grey supercilium and face, slightly paler, grizzled loreal area; forehead and forehead dark grey-brown, hindcrown and hindneck dark rufous, back to uppertail-coverts brown with rufescent tinge, wing-coverts dark rufous (upperparts brightest in NE, duller and greyer with wing-coverts browner in SW); remiges paler and tawnier than coverts, with dusky tips; tail long, graduated, rectrices only slightly pointed, dark rufous, inner webs of central pair variably dull rufous to darker fuscous; chin whitish, blending to greyer upper throat, roughly crescent-shaped blackish patch with some pale speckling on lower throat; dull greyish-brown below, paler belly whitish in centre, flanks and undertail-coverts browner; iris chestnut to rufous to yellow (source of variation unknown); upper mandible blackish to dark grey, lower mandible grey to pale grey, sometimes with blackish tip; tarsus and toes olive-grey to greenish-grey. Sexes alike. Juvenile lacks contrasting crown, has underparts somewhat washed ochraceous. Voice. Most frequent vocaliza-

tion a sharp double note described as "ka-kwee-éék", "ka-kweek", "pi-whée" or "ja-coo-éé", often repeated for extended periods; also gives "tsew-klí" or "chi-clí", and repeated nasal "choint" or "choit".

**Habitat.** Tropical deciduous forest, gallery forest edge, secondary forest edge; undergrowth and edge of scrubby or deciduous forest, gallery forest, edge of riparian woodland in arid areas, thornscrub, bushy savanna, and early-successional second growth; also hedgerows in agricultural areas. To 2500 m.

**Food and Feeding.** Little published information. Recorded dietary items include Coleoptera. Usually found in pairs, generally in understorey, occasionally descending to ground. Probably gleans arthropods from foliage and small branches, mainly within 1-2 m of ground.

**Breeding.** Season during austral spring-summer; eggs in Oct-Mar in NW Argentina. Presumably monogamous. Nest a globular mass c. 20-40 cm long, 20 cm wide, 25-30 cm high, made from twigs, often thorny ones, external entrance tube c. 15-30 cm long, inner chamber with bed of dead leaves, twigs, lichens, moss and feathers c. 12 cm in diameter; placed 0.5-4 m (mostly 1-2.5 m) above ground in thorny bush. Clutch 3-4 eggs; incubation period 15-16 days. Nests parasitized by Striped Cuckoo (*Tapera naevia*).

**Movements.** Resident; populations breeding in extreme S suspected of being partially migratory.

**Status and Conservation.** Not globally threatened. Common to fairly common, including in heavily disturbed habitats. Occurs in Serra do Cipó and Chapada dos Guimarães National Parks and Pedra Talhada State Park, in Brazil, and in Calilegua and El Rey National Parks and Costanera Sur Ecological Reserve, in Argentina. Has extended its range into deforested areas.

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Chesser (1994), Cory & Hellmayr (1925), Cuello (1985), Di Giacomo & López (1998), Ferreira de Vasconcelos & Melo-Júnior (2001), Fjeldsa & Krabbe (1990), Fjeldsa & Maljer (1996), Guerrero & Arambiza (2001), Hayes (1995), Hayes & Scharf (1995b), Herzog *et al.* (1999), Hoy (1968b), Kirwan *et al.* (2001), Krabbe *et al.* (1996), Kratter *et al.* (1993), Lowen, Bartrina, Clay & Tobias (1996), Maceda *et al.* (1997), Marini (2001), Mazar Barnett & Pearnan (2001), Melo-Júnior *et al.* (2001), Narosky *et al.* (1983), do Nascimento *et al.* (2000), Naumburg (1930), Navas & Bö (1988), Norez *et al.* (1983), Ochoa (1971), Olrog (1963a), Parker, Gentry *et al.* (1993), Parrini *et al.* (1999), Partridge (1953), de la Peña (1987, 1988, 1996, 1997), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Salvador (1988, 1990), Schmitt *et al.* (1997), Short (1975), Sick (1993, 1997), Silveira (1998), Stotz *et al.* (1996), Vaurie (1971d), Wetmore (1926), Zotta (1938).

## 75. Azara's Spinetail

### *Synallaxis azarae*

**French:** Synallaxe d'Azara

**German:** Azaradickichtschlüpfer

**Spanish:** Pijui de Azara

**Other common names:** Buff-browed Spinetail (*superciliosa* with *samaipatae*); Elegant Spinetail (*elegantior* with *media*, *ochracea* and *fruticicola*)

**Taxonomy.** *Synallaxis Azarae* d'Orbigny, 1835, Carcuata, Yungas, Cochabamba, Bolivia.

Considered by some authors to form a superspecies with *S. frontalis* and *S. courseni* on basis of plumage and vocal similarities. C Peruvian populations may be closer genetically to latter than they are to geographically distant populations of present species, constitution of which would thereby be rendered paraphyletic. Races *superciliosa* and *samaipatae* formerly treated as representing a separate species, but voice and evidence of introgression suggest that they are better considered conspecific. Races *elegantior* and *ochracea* possibly indistinguishable from each other but separated geographically by *media*; all three, together with *fruticicola*, sometimes treated as forming a separate species, originally on basis mainly of vocal differences (not confirmed subsequently) and difference in number of rectrices. Proposed race *carabayae*, described from S Peru (Puno) and N Bolivia (La Paz), purportedly darker than nominate, but individual specimens of the two forms found to be indistinguishable. Nine subspecies recognized.

**Subspecies and Distribution.**

*S. a. elegantior* P. L. Selater, 1856 - E Andes of Colombia and W Venezuela (Trujillo and SE Lara S to Tachira).

*S. a. media* Chapman, 1914 - W & C Andes of Colombia S to Ecuador (S to Cotopaxi in W and to Zamora-Chinchipe in E), possibly also in N Peru (extreme NE Cajamarca).

*S. a. ochracea* J. T. Zimmer, 1936 - Andes of SW Ecuador (S from Guayas and S Chimborazo) and NW Peru (Tumbes S to Lambayeque).

*S. a. fruticicola* Taczanowski, 1880 - Marañón Valley in N Peru (Cajamarca S to La Libertad).

*S. a. infumata* J. T. Zimmer, 1925 - Andes of N & C Peru (Amazonas S to Junin).

*S. a. urubambae* J. T. Zimmer, 1935 - S Peru (Cuzco).

*S. a. azarae* d'Orbigny, 1835 - S Peru (Puno) S to C Bolivia (La Paz S to NW Santa Cruz).

*S. a. samaipatae* Bond & Meyer de Schauensee, 1941 - S Bolivian Andes (C Santa Cruz S to Tarija).

*S. a. superciliosa* Cabanis, 1883 - Andes of NW Argentina (Jujuy S to Catamarca).

**Descriptive notes.** 15-17 cm; 12-18 g. Nominate race has dark brownish-grey face, slightly paler supercilium; forehead and forehead dark greyish-brown, hindcrown and hindneck dark rufous, back to uppertail-coverts rich olive-brown; wings mainly rufous-chestnut except for dark brownish tips of remiges; tail long, graduated, 8 rectrices, these disintegrated towards tips and somewhat pointed, dull chestnut-brown; chin and borders of throat pale greyish with darker feather tips, triangular central throat patch sooty-black with pale grey feather margins; breast dark brownish-grey, belly paler and greyer with faint mottling, flanks and undertail-coverts browner; iris reddish-brown to chestnut; upper mandible black to dark grey, lower mandible grey or blue-grey, sometimes with blackish base or tip; tarsus and toes olive-grey to greyish-green. Sexes alike. Juvenile has crown and back brown, throat patch indistinct, underparts washed pale brown to ochraceous, mainly on breast, with some darker brown edgings. Races vary in "leap-frog" manner, with alternating series of "pale" and "dark" populations: *elegantior* is paler than nominate, with buffy or greyish supercilium poorly defined,

white loreal spot, more fulvous flanks, usually 10 rectrices, juvenile underparts more strongly washed ochraceous; *media* is like previous, but supercilium grey and even less contrasting, loreal spot smaller, chest greyer, flanks paler and more olivaceous; *ochracea* is pale, has crown and wing-coverts paler, back more buffy brown, narrower frontal band, very pale grey below, flanks tinged ochraceous; *fruticicola* is slightly darker than previous, frontal band broader; *infumata* is darker throughout than last, has 8 rectrices, most similar to nominate but grey frontal band wider, wing-coverts brighter shade of rufous; *urubambae* differs from last in having darker tail tinged olivaceous grey (especially basally), rufous margins of remiges duller and contrasting with brighter wing-coverts; *samaipatae* is relatively pale, has forehead feathers indistinctly edged rufous, thin supercilium buffish, face and breast medium grey (intermediate in several ways between nominate and next); *supercilliosa* has more prominent pale buff supercilium, light buffy brown underparts with whitish belly. **VOICE.** Most frequent vocalization a sharp "ket-kwééék" or "pip-squeak" c. 1 second long, second note occasionally repeated, given at intervals of 1-4 seconds. Also gives series of scratchy, nasal "prrrt" notes, sometimes interspersed with "kweek-kweek" notes; alarm a low short "chur" or "trrrt".

**Habitat.** Montane evergreen forest edge, secondary forest; dense undergrowth at edge of humid cloudforest and elfin forest, second growth, bamboo thickets, regenerating clearings and landslides, overgrown pastures, bushy roadsides; also riparian thickets in drier areas. Occurs in deciduous and semi-deciduous forest in Argentina (*supercilliosa*). Mainly 1500-3500 m, but down to 900 m in SW Ecuador; mainly 600-1600 m in S Bolivia and Argentina.

**Food and Feeding.** Mostly arthropods, including moth larvae; some small seeds also recorded in diet. Usually in pairs, occasionally also in mixed-species flocks. Gleans prey from foliage, small branches and occasionally dead leaves, usually within 1-2 m of ground but at times as much as 6 m above it.

**Breeding.** Breeds during both wet and dry months and possibly throughout year in W Colombia; eggs in Feb-Apr in Colombia and Ecuador and Oct-Nov in NW Argentina; fledglings in May-Sept in Colombia S to N Peru. Monogamous. Nest a bulky elongated mass of sticks with horizontal or upward-inclined entrance tube 30-40 cm long, densely thatched above interior chamber, which lined with soft plant material and, occasionally, some snake skin; placed in low, dense vegetation. Clutch 2 eggs, but up to 4 in Argentina (*supercilliosa*). Nests frequently usurped by Bay-winged Cowbird (*Agelaioides badius*) in Argentina.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common over most of its extensive range. Occurs in numerous protected areas. Tolerates moderate anthropogenic disturbance; presumably benefits from forest fragmentation.

**Bibliography.** Bond (1945), Canevari *et al.* (1991), Chapman (1926), Cook (1996), Cory & Hellmayr (1925), Field & Krabbe (1990), Fjeldså & Maijer (1996), Friedmann (1927), Herzog *et al.* (1999), Hilty (1985, 2003a), Hilty & Brown (1983, 1986), Koepecke (1961a), Krabbe *et al.* (1996), Miller (1960, 1963), Narosky *et al.* (1983), Norez & Yzurieta (1983a), Norez *et al.* (2000), Olrog (1963a), Parker, Parker & Plenge (1982), Parker, Schulenberg, Graves & Braun (1985), Parker, Schulenberg, Kessler & Wust (1995), Peña (1997), de la Peña (1988), Remsen (1985, 2003a), Remsen & T aylor (1989), Remsen *et al.* (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman (1994), Salaman *et al.* (1999), Salvador (1988), Schulenberg & Awbrey (1997a), Stotz *et al.* (1996), Taczanowski (1884), Vaurie & Schwartz (1972), Walker (2001), Zimmer (1930, 1935b, 1936b).

## 76. Apurimac Spinetail

### *Synallaxis courseni*

**French:** Synallaxe de Coursen

**Spanish:** Pijui de Apurimac

**German:** Langschwanz-Dickichtschlüpfer

**Other common names:** Blake's/Coursen's Spinetail

**Taxonomy.** *Synallaxis courseni* Blake, 1971, Bosque Ampay (Abancay), 9000 feet [c. 2750 m], Apurimac, Peru.

Considered by some authors to form a superspecies with *S. frontalis* and *S. azarae* on basis of plumage and vocal similarities. Biogeography, habitat and voice strongly suggest that it is a derivative of latter. Proposal by others that this species is related to *S. brachyura* considered a very unlikely one. Monotypic.

**Distribution.** C Peruvian Andes on S slopes of Nevada Ampay, N of Abancay (Apurimac).

**Descriptive notes.** 17-18 cm; 15 g. Has dark grey forehead and face slightly tinged brownish, paler supercilium behind eye; hindcrown and hindneck dark rufous, back to uppertail-coverts dark grey with slight olive tinge; wings mostly bright orange-rufous except for dark brownish tips of remiges; tail very long, graduated, 10 rectrices, outer pairs disintegrated towards tips and somewhat pointed, dark sooty-brown, shafts of outer pairs of rectrices with dull rufous tones; throat patch sooty-black with pale grey feather margins; underparts rather uniform dark grey, flanks washed olive; iris chestnut; upper mandible black, lower

mandible blue-grey with black tip; tarsus and toes greenish-grey. Distinguished from similar *S. azarae* by much longer and darker tail with 10, not 8, rectrices, generally greyer appearance. Sexes alike. Juvenile has crown and back brown, throat patch indistinct, underparts washed pale brown to ochraceous. **VOICE.** Most frequent vocalization a sharp "ka-kwééék", often repeated, indistinguishable from that of *S. azarae*, and responds strongly to playback of latter.

**Habitat.** Dense undergrowth at edge of semi-humid forest (*Podocarpus hermsianus*), second growth, regenerating clearings and landslides, especially in bamboo thickets; 2450-3500 m.

**Food and Feeding.** Arthropods. Forages usually in pairs, in understorey. Gleans items from foliage and small branches in undergrowth, occasionally up to 3 m above ground.

**Breeding.** Virtually nothing known. Birds with large gonads in Dec; immatures seen in Mar.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Peruvian High Andes EBA. Common to rare in appropriate habitat, but has tiny range of only 36 km<sup>2</sup>. Total population estimated at 300-400 pairs in 1990s. Entire range is officially protected, constituting the Ampay National Sanctuary. No data available on population trends.

**Bibliography.** Blake (1971), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså (1987), Fjeldså & Krabbe (1986, 1990), Mayr & Vuilleumier (1983), Parker *et al.* (1982), Remsen (2003a), Remsen *et al.* (1988), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

## 77. Pale-breasted Spinetail

### *Synallaxis albesceus*

**French:** Synallaxe albane **German:** Weißbauch-Dickichtschlüpfer **Spanish:** Pijui Pechiblanco  
**Other common names:** White-throated Spinetail, Pale-breasted Castlebuilder

**Taxonomy.** *Synallaxis albesceus* Temminck, 1823, Cemiterio do Lambari, near Sorocaba, São Paulo, Brazil.

Close relationship to *S. albigularis* and *S. spixi* suggested by plumage and vocal similarities. Considered by some authors to be possibly the sister-species of former, which was once regarded as conspecific; proposed race *pullata* is a synonym of nominate race of that species. Reported vocal differences of race *australis* suggest that it may be a separate species. Geographical variation tends to follow Gloger's Rule, with populations from arid areas usually the palest in coloration; some of the described variation, however, probably due to individual and age variation in small sample sizes, and many of the races tentatively recognized (especially those in N South America) are likely to be synonymized once a quantitative analysis of geographical variation is conducted. Proposed race *hypoleuca* (C Panama), described as paler below, is considered by most authors to be synonymous with *latitabunda*. Race *nesiotis* originally described (from Margarita I, off N Venezuela) as like nominate but paler, but, with its distribution expanded to include large areas of mainland, its distinguishing characters are unclear; proposed race *trinitatis* (Trinidad and N Venezuela) said to have darker crown and wing-coverts and more buff-brown back than that race, but these characters not corroborated by subsequent authors. Proposed race *griseonota*, from confluence of R Tapajós and R Amazon (Brazil), described as having paler crown and wing-coverts and more greyish underparts than *inaequalis*, but, since latter recorded from both E and W of that area, its acceptance as a valid taxon requires corroboration. Ten subspecies tentatively recognized.

**Subspecies and Distribution.**

*S. a. latitabunda* Bangs, 1907 - SW Costa Rica, Panama and NW Colombia.

*S. a. littoralis* Todd, 1948 - coast of N Colombia.

*S. a. insignis* J. T. Zimmer, 1935 - N & C Colombia (Cauca and Magdalena Valleys, and Boyacá) and W Venezuela (S Apure).

*S. a. perpallida* Todd, 1916 - extreme N Colombia (Guajira Peninsula) and NW Venezuela (NW Zulia E to W Falcón, S to N shore of L Maracaibo and Lara).

*S. a. occipitalis* Madarász, 1903 - NW Venezuela (Perijá Mts, Mérida, Táchira) and NC Colombia (Norte de Santander, Santander), evidently in montane areas.

*S. a. nesiotis* A. H. Clark, 1902 - N Colombia (Santa Marta region) and N Venezuela (S Táchira and Apure E to Sucre, Monagas, extreme N Amazonas and N Bolívar, also Margarita I and Cubagua I); also Trinidad, including Bocas Is.

*S. a. josephinae* Chubb, 1919 - S Venezuela (C Amazonas, C Bolívar, Guyana, Surinam and N Brazil (Roraima).

*S. a. inaequalis* J. T. Zimmer, 1935 - French Guiana and NC Brazil (both sides of R Amazon between R Madeira and R Tapajós).

*S. a. australis* J. T. Zimmer, 1935 - extreme SE Peru (Madre de Dios), E Bolivia (Beni S to Tarija and Santa Cruz), W Paraguay, NW & C Argentina (Salta and Formosa S to Mendoza, La Pampa and Buenos Aires).

*S. a. albesceus* Temminck, 1823 - S & E Brazil, E Paraguay and NE Argentina (Misiones).

**Descriptive notes.** 13-16 cm; 9-17 g. Typical *Synallaxis* but slightly smaller and shorter-billed than most. Nominative race has pale brownish-grey face with weakly defined pale eyeline; forehead dull olive greyish-brown, blending to dark rufous crown, crown often slightly mottled and weakly defined (source of variation unknown); upperparts dull olive-brown; rufous wing-coverts contrasting with tawny-brownish remiges; tail long, graduated, 10 rectrices, these somewhat pointed (but blunter than on many congeners), olive-brown, outer rectrices variably tinged somewhat more rufescent; throat whitish, irregular black fleck-

ing in centre of lower throat; breast pale buffy grey, blending to paler belly, browner flanks and undertail-coverts; iris yellowish to light brown or brown (source of variation unknown); upper mandible black to dark grey, lower mandible blackish to grey with dark tip or uniform grey; tarsus and toes yellowish-brown to greyish-olive or brownish-yellow. Sexes alike. Juvenile lacks contrasting crown, has upperparts paler and often slightly more rufescent (especially wing-coverts) than adult, throat patch less distinct, underparts paler, almost white on throat and centre of belly. Race *latitabunda* is darker than nominate, tail and flanks browner; *perpallida* is generally like previous but less rufescent, more greyish, above, crown and wing-coverts darker rufous and more extensive, very white below; *occipitalis* is darker throughout, with blackish, not greyish, forehead; *insignis* resembles last but general colour paler, rufous of crown less extensive, thus greyish of forehead more extensive, back paler with brownish tinge, upperwing-coverts paler, malar region paler grey, breast paler and less greyish; *littoralis* differs from previous in more brownish, less greyish, upperparts, on average underparts with less greyish wash; *nesiotis* has paler, more yellowish-tinged crown and shoulder area than nominate, paler and greyer upperparts, whiter below, paler undertail-coverts, creamy (not buff) underwing-coverts, but possibly variable; *josephinae* is like last but darker overall, face darker grey, back less buff-brown, breast more greyish, flanks darker brownish; *inaequalis* is much paler than previous, rufous of cap and wing-coverts paler, back with greyish tinge, throat and belly whiter, breast pale grey or whitish, flanks greyish with little buff; *australis* resembles nominate but rufous crown feathers tipped olive, back duller, more greyish-brown, outer margins of wing-coverts with rufous usually restricted to bases, throat feathers with broader whitish tips. **VOICE.** Most frequent vocalization a buzzy, nasal "wée-byew", "wake-up", or (*latitabunda*) "wa-ter", often repeated for long periods, e.g. up to 30 minutes at 35-40 songs per minute; also two-parted "brri-drr, wi-deh"; described as shriller and higher-pitched "whii-whzesu" in SW of range (*australis*); voice of *nesiotis* slightly more variable on Margarita I than on Venezuelan mainland. Call described (from Costa Rica) as sharp "bip", often repeated rapidly and followed by long rattling "churrur".

**Habitat.** *Cerrado*, campo grasslands, pastures/agricultural lands, second-growth scrub; variety of open areas as long as extensive grass present: grassland, savanna, regenerating pasture, shrub-steppe, brush in open woodland, marsh edges, second growth and overgrown roadsides. Mostly below 1500 m.

**Food and Feeding.** Recorded food items are orthopterans, including grasshoppers (Acrididae), also stick-insects (Phasmidae). Coleoptera (including the families Curculionidae, Chrysomelidae), Hemiptera, Homoptera, ants (Myrmicinae), caterpillars, spiders, and a small snail. Usually forages

in pairs, rarely in mixed-species flocks. Gleans prey items from foliage, grass and small branches, usually within 1-2 m of ground; also from ground.

**Breeding.** Breeds in Dec-Sept in Trinidad and during austral spring-summer in Argentina; eggs in May-Jul in Costa Rica, May in Panama, Jan-Feb and May-Oct in Surinam and Nov-Feb in Argentina; nestlings in Feb in Argentina. Presumably monogamous. Nest a globular mass c. 15-20 cm tall and 18-30 cm long, of dried grasses and twigs, latter up to 18 cm long and sometimes thorny, often snake skin and sometimes spider webs incorporated, straight horizontal entrance tube (sometimes two tubes) c. 15-40 cm long, inner chamber c. 10 cm in diameter, covered by thatch of coarse plant material, lined with soft plant material such as pubescent *Solanum* leaves or seed down; placed 0.6-2 m above ground, rarely to 9 m, usually in large clump of bunch-grass or bush overgrown with vines, once on top of old nest of mockingbird (*Mimus*). Clutch 2-4 eggs; incubation by both sexes, period c. 15-18 days; nestling period c. 16 days. Nests regularly parasitized by Striped Cuckoo (*Tapera naevia*).

**Movements.** Presumably resident; populations breeding in extreme S of range suspected of being at least partially migratory.

**Status and Conservation.** Not globally threatened. Fairly common to common over most of its large range; local or scarce in some regions, e.g. Santa Catarina (SE Brazil). Tolerant of moderate anthropogenic disturbance, provided that adequate areas of tall grass remain. Expanding its range in areas that have been cleared.

**Bibliography.** Alves & Cavalcanti (1996), Belcher & Smoother (1936), Bond (1956), Braze & Hornbuckle (1998), Braze *et al.* (1997), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1931), Chesser (1994), Clark (1902), Cory & Hellmayr (1925), Ferreira de Vasconcelos & Melo-Júnior (2001), French (1991), Fjeldså & Maijer (1996), Fraga & Narosky (1985), Guerrero & Arambiza (2001), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003a), Hilty & Brown (1986), Lindell (1998), Melo-Júnior *et al.* (2001), Meyer de Schauensee (1945), Miller (1955), Morton (1979), Naka *et al.* (2001), Narosky *et al.* (1983), Navas & Bö (1988), Norez *et al.* (1983), Olrog (1963a), Parker (1982), Parker & Bailey (1991), Parker, Gentry *et al.* (1993), Parker, Parker & Plenge (1982), Parrini *et al.* (1999), de la Peña (1987, 1988), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Wynne (1989), Ridgely & Tudor (1994), Ripley (1955), Rodner *et al.* (2000), Salaman (1994), Salvador (1988), Schubart *et al.* (1965), Selater & Salvin (1879), Serié & Smyth (1923), Short (1975), Sick (1993, 1997), da Silva *et al.* (1997), Skutch (1969c, 1985, 1987), Slud (1964), Smyth (1928), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Todd (1948b), Tostain *et al.* (1992), Wetmore (1926, 1972), Zimmer, J.L. ## 78. Dark-breasted Spinetail

*Synallaxis albigularis*

**French:** Synallaxe à gorge blanche

**Spanish:** Pijui Pechioscuro

**German:** Dunkelbrust-Dickichtschlüpfer

**Taxonomy.** *Synallaxis albigularis* P. L. Selater, 1858, Rio Napo, Ecuador.

Close relationship to *S. albescens* and *S. spixi* suggested by plumage and vocal similarities. Considered by some authors to be possibly the sister-species of former, and was once regarded as conspecific; proposed race *pullata* of that species is a synonym of nominate race of present species. Larger birds with much darker underparts, found in Huallaga and Ucayali drainages of Peru, appear to represent an undescribed race. Two subspecies recognized.

### Subspecies and Distribution.

*S. a. rodolphei* Bond, 1956 - S Colombia (Meta S to Putumayo) and NE Ecuador (Sucumbfos, N Napo). *S. a. albigularis* P. L. Selater, 1858 - E Ecuador (S from S Napo), SE Colombia (extreme S Amazonas), E Peru (Amazonas S to Madre de Dios) and W Brazil (E, mainly along R Amazon, to R Negro).

**Descriptive notes.** 15-16 cm; 14-18 g. Typical *Synallaxis* with contrasting crown and wings, dark throat patch. Nominative race has dark brownish-grey forecrown, supercilium and face; hindcrown and hindneck dark rufous, back to uppertail-coverts olive-brown; dark rufous shoulder with duller paler edges to greater wing-coverts; remiges dark brownish; tail long, graduated, 10 rectrices rather pointed, dull brown; throat greyish-white with irregular sooty flecks, feathers of central lower throat blackish with pale grey margins; breast and sides dull brownish-grey, blending to paler belly (nearly white in centre), browner flanks and undertail-coverts;

iris reddish-brown to brown or pale brown (source of variation unknown); upper mandible black to dark grey, lower mandible greyish to blue-grey; tarsus and toes greenish-grey to greenish-yellow. Sexes alike. Juvenile lacks contrasting crown, has paler upperparts than adult, throat patch less distinct and paler, underparts mostly uniform dark ochraceous. Race *rodolphei* is darker, especially below, whitish centre of belly contrasts more with rest of underparts, back also slightly darker. Voice. Most frequent vocalization a hurried "chéép, du-du-du" or "whit, di-di-di", often repeated for long periods; occasionally gives short chatter while perched in relatively exposed place.

**Habitat.** River-island scrub and second-growth scrub; middle-aged and young river islands with *Gynerium* cane, tall grass, and low shrubs (especially *Tessaria*), also overgrown grassy clearings, plantations. From sea-level to 1500 m, locally to 2100 m.

**Food and Feeding.** Arthropods. Usually in pairs; gleans items from small branches and foliage within 1-2 m of ground, also from ground itself.

**Breeding.** Eggs in Jun-Jul in Colombia. Presumably monogamous. Nest a mass of sticks c. 40-50 cm long, tubular entrance, placed 1-2 m above ground in dense vegetation. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common within somewhat limited range. Occurs in a number of protected areas, including Cuyabeno Reserve, in Ecuador, and Manu National Park and Biosphere Reserve, in Peru. Present in many areas of high anthropogenic disturbance. Is expanding its range into deforested areas.

**Bibliography.** Balchin & Toyne (1998), Bond (1956), Chapman (1931), Cherrie (1916b), Cory & Hellmayr (1925), Foster *et al.* (1994), Hilty & Brown (1986), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Parker (1983), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1995, 1997), Rosenberg, G.H. (1990), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh & Weske (1969), Zimmer (1936b).

## 79. Spix's Spinetail

*Synallaxis spixi*

**French:** Synallaxe de Spix

**German:** Spixdickichtschlüpfer

**Spanish:** Pijui Plomizo

**Other common names:** Chicli Spinetail

**Taxonomy.** *Synallaxis Spixi* P. L. Selater, 1856, São Paulo, Brazil.

Close relationship to *S. albescens* and *S. albigularis* suggested by plumage and vocal similarities. In the past was considered conspecific with *S. hypospodia*; the two are thought to be possibly sister-species by some authors, but others consider them not closely related because of differences in tail morphology, throat pattern and voice. Monotypic.

**Distribution.** E Paraguay, SE Brazil (S from SE Bahia and S Espírito Santo), NE Argentina (S to E Santa Fe, Entre Ríos and N Buenos Aires) and Uruguay.

**Descriptive notes.** 16-17 cm; 12-14 g. Typical *Synallaxis* with contrasting crown and wings, dark throat patch. Face is dark greyish-brown with paler eyeline; forehead to hindneck rufous, upperparts dark brown; rufous lesser wing-coverts, dark brown median and greater coverts with broad rufous margins, dark brown remiges; tail long, graduated, 10 rectrices, central pair highly disintegrated towards tips and sharply pointed, dark brown; throat greyish-white, most of lower throat black with feathers edged greyish; breast-brownish grey, blending to paler belly, browner flanks and undertail-coverts; iris reddish to orange-brown; upper mandible black, lower mandible grey; tarsus and toes greenish-grey to greyish-olive. Sexes alike. Juvenile lacks contrasting crown colour, has upperparts slightly darker than adult, throat patch less distinct, underparts mostly ochraceous brown, lower mandible pinkish. Voice. Most frequent vocalization a hurried "whit, di-di-di" or "swéet, bee-bee-bee-bee", often repeated quickly for long periods.

**Habitat.** Second-growth scrub, riparian thickets and *cerrado*; open areas, usually with mix of tall grass and shrubs, and woodland edge, often near water. From near sea-level to 2050 m.

**Food and Feeding.** Little known. Usually in pairs, mainly in understorey, occasionally on ground. Presumably gleans arthropods from foliage and small branches within 2 m of ground.

**Breeding.** Season during austral spring-summer; eggs in Nov-Jan in Argentina. Presumably monogamous. Nest a globular or cylindrical mass c. 20-30 cm long, 25-30 cm high, made from sticks, usually thorny, often with snake or lizard skins (and occasionally wire) incorporated, lateral entrance tube c. 25 cm long, inner chamber with particularly dense "roof" of branches and bark that evidently provides additional protection from rain, and with lining c. 12-15 cm across of leaves (sometimes of *Solanum*), mosses and hair; placed 1-2 m up in bush or small tree. Clutch 3-5 eggs. Nests regularly parasitized by Striped Cuckoo (*Tapera naevia*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common over much of its range; rare in extreme S. Occurs in several protected areas. Presumably benefits from deforestation.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Anon. (2003d), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Di Giacomo (1995), Euler (1900), Ferreira de Vasconcelos & Melo-Júnior (2001), Fraga & Narosky (1985), Goerck (1999a), Hayes (1995), Madroño, Clay *et al.* (1997), Madroño, Robbins & Zyskowski (1997), Mazar Barnett & Pearman (2001), Melo-Júnior *et al.* (2001), Naka *et al.* (2002), Narosky *et al.* (1983), Navas & Bö (1988), Parker & Goerck (1997), Parrini *et al.* (1999), de la Peña (1987, 1988, 1997), Pereyra (1927), Pinto (1978), Ridgely & Tudor (1994), Scott & Brooke (1985), Serié & Smyth (1923), Sick (1993, 1997), Silveira (1998), Stotz *et al.* (1996), Wetmore (1926).

## 80. Cinereous-breasted Spinetail

*Synallaxis hypospodia*

**French:** Synallaxe cendré

**German:** Graubrust-Dickichtschlüpfer

**Spanish:** Pijui Cenizo

**Other common names:** Jaragua Spinetail ("Jaraguana")

**Taxonomy.** *Synallaxis hypospodia* P. L. Selater, 1874, near Bahia, Brazil.

Was in the past considered a subspecies of *S. spixi*; the two are thought to be possibly sister-species by some authors, but others consider them not closely related because of differences in tail morphology, throat pattern and voice. Named taxon *jaraguana* from E Brazil (Goiás), described as a race of *S. brachyura*, was based on misidentified specimens of present species. Monotypic.

**Distribution.** SE Peru (Cuzco, Madre de Dios), N & E Bolivia (NW La Paz, Beni, N Santa Cruz) and SC & E Brazil (locally in S Amazonia from Amazonas E to R Tapajós, and Mato Grosso E to Ceará, Alagoas, N Bahia and W Minas Gerais).

**Descriptive notes.** 15-16 cm; 15-18 g. Typical *Synallaxis* with contrasting crown and wings, dark throat patch. Has dark grey-brown forecrown, grey-brown face with hint of grey supercilium; rest of crown and hindneck chestnut-rufous, back to uppertail-coverts dark brown; chestnut-rufous wing-coverts, dark brown remiges edged rufescent; tail long, graduated, 10 rectrices rather broad and rounded (far less pointed than in most congeners), darker than back; chin and throat whitish, bases of feathers black, lower throat mainly black with narrow whitish edges; breast brownish-grey, belly whitish, flanks and undertail-

coverts brownish; iris reddish-brown; upper mandible black, lower mandible silvery grey to greyish horn; tarsus and toes olive or greyish-olive to brownish-yellow. Sexes alike. Juvenile lacks contrasting crown colour, has throat patch less distinct, underparts mostly ochraceous clay-brown. Voice. Most frequent vocalization a hurried and loud chatter on same pitch, "chéw, chew-chee-chee-chee-ee-ee-ee-ee-eu", accelerating at end, described by some as similar in quality to that of *S. albigularis*.

**Habitat.** Low, seasonally wet grassland, and second-growth scrub; in open areas with mix of low shrubs and grass, often near water, and including *campinas* and savanna. Recorded up to 700 m.

**Food and Feeding.** Little known. Usually seen in pairs. Presumably gleans arthropods from foliage and small branches within 1-2 m of ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common to fairly common; relatively poorly known. Somewhat fragmented distribution, with isolated populations in S Peru; specimens reported from N & C Peru (San Martín, Junín) probably misidentified.

**Bibliography.** Brace & Hornbuckle (1998), Cory & Hellmayr (1925), Parker *et al.* (1982), Pinto (1936, 1978), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Straube & Bornschein (1991a), Willis & Oniki (1990), Zimmer (1936b).

## 81. Ruddy Spinetail

### *Synallaxis rutilans*

**French:** Synallaxe ardente **German:** Schwarzkehl-Dickichtschlüpfer **Spanish:** Pijui Rojizo  
**Other common names:** Temminck's Spinetail

**Taxonomy.** *Synallaxis rutilans* Temminck, 1823, Cametá, Rio Tocantins, Brazil.

Almost certainly the sister-species of *S. cherriei*, type specimen of which was once considered an aberrant individual of race *amazonica* of present species. Distinctive race *omissa* suggested as being possibly a separate species. Differentiation and distribution of other races uncertain, and present arrangement tentative; some listed races possibly not distinguishable, while small series of specimens from N Bolivia suggests that darkness of plumage coloration varies clinally from W Amazonia to extreme E Bolivia (near type locality of *tertia*); thorough analysis needed. Seven subspecies recognized.

#### **Subspecies and Distribution.**

*S. r. dissors* J. T. Zimmer, 1935 - E Colombia (Vichada, Guainía), S Venezuela (Amazonas, Bolívar), the Guianas and N Brazil (E of R Negro).

*S. r. caquetensis* Chapman, 1914 - SE Colombia (S from Meta and Vaupés), E Ecuador and NE Peru.

*S. r. confinis* J. T. Zimmer, 1935 - NW Brazil (W of R Negro).

*S. r. amazonica* Hellmayr, 1907 - E Peru, W & C Brazil (S of R Amazon, E to R Tapajós) and N Bolivia (Pando, La Paz, N Beni).

*S. r. rutilans* Temminck, 1823 - EC Brazil from R Tapajós E to R Tocantins, S to NE Mato Grosso.

*S. r. omissa* Hartert, 1901 - R Tocantins E to N Maranhão (E Brazil).

*S. r. tertia* Hellmayr, 1907 - SW Brazil (S to SW Mato Grosso) and E Bolivia (E Santa Cruz).

**Descriptive notes.** 13-14 cm; 15-22 g. Distinctive *Synallaxis* with plumage mostly chestnut and blackish. Male nominate race has forecrown and face deep ruddy chestnut, loreal region mottled blackish; hindcrown to back chestnut with strong olive-brown wash (especially on hindcrown), rump and uppertail-coverts dull dark brown; wing-coverts mostly chestnut, remiges fuscous with dull chestnut margins; tail long, graduated, 10 rectrices moderately pointed, slaty blackish; throat black, breast bright ruddy chestnut like face, belly and undertail-coverts dark olive-brownish, occasionally faint paler shaft streaks.

flanks slightly browner; iris brown to chestnut-red; upper mandible black, lower mandible black, sometimes with grey base, to blue-grey; tarsus and toes olive-grey to dark grey or black (source of variation in bare-part colours unknown, perhaps geographical). Distinguished from similar *S. cherriei* mainly by dark throat. Female is slightly paler than male, and more washed with olive. Juvenile is duller, less rufous, than adult, throat grey, vaguely streaked below, especially on belly. Race *dissors* differs from nominate mainly in slightly less olivaceous back, interscapular area with little or no chestnut patch, browner scapulars with reduced chestnut area; *caquetensis* has crown and back mostly rufous-chestnut, flanks and centre of belly olive-tinged fuscous; *confinis* is generally paler chestnut throughout, lacks traces of olive on nape, has browner outer webs of remiges; *amazonica* has crown and back often suffused with brown, rump and uppertail-coverts sooty blackish; *tertia* differs from previous in having rump and uppertail-coverts brown, instead of sooty blackish; *omissa* is distinctive in having plumage mostly fuliginous, with rufous only on wings, often rufous wash on breast, remarkably similar to juvenile plumages of other races. **Voice.** Most frequent vocalization a nasal "kéé-kawow", "tae, tae-owet", "kit-naaa" or "chick-dawah", often doubled, usually repeated at c. 1-second intervals, sometimes for long periods.

**Habitat.** Tropical lowland evergreen forest; undergrowth of tropical forest (mainly *terra firme*), especially in or around treefall gaps. Usually occupies less disturbed or less open forest than *S. cherriei* where the two occur sympatrically. To 900 m; to 1200 m in S Venezuela.

**Food and Feeding.** Recorded dietary items are Coleoptera (including Curculionidae), shield-bugs (Pentatomidae), cicadas (Cicadidae), cockroaches (Blattodea), ants and other Hymenoptera, caterpillars, Diptera, spiders. Forages usually in pairs, occasionally in mixed-species flocks, on or within 1-2 m of ground. Gleans arthropods from leaf litter, dead-leaf clusters, dense foliage and small branches.

**Breeding.** Nest a globular mass of twigs with long horizontal entrance tunnel. Clutch 3-4 eggs. No other information.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common over most of its extensive range. Local in F Ecuador. Occurs in numerous protected areas.

**Bibliography.** Barnett *et al.* (2002), Blake (1950b), Cadena, Alvarez *et al.* (2000), Cory & Hellmayr (1925), Foster *et al.* (1994), Graves & Zusi (1990), Gyldenstolpe (1930a, 1945b), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee (1945), Naumburg (1930), Novaes (1990), Oren & Parker (1997), Parker & Bailey (1991), Parker *et al.* (1982), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Schubart *et al.* (1965), Sick (1993, 1997), da Silva *et al.* (1990), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer & Bierregaard (1995), Taczanowski (1884), Terborgh *et al.* (1984), Tostain *et al.* (1992), Whitney & Pacheco (1994), Zimmer, J.T. (1935b, 1936b), Zimmer, K.J. & Hilty (1997), Zimmer, K.J., Parker *et al.* (1997).

## 82. Chestnut-throated Spinetail

### *Synallaxis cherriei*

**French:** Synallaxe à gorge marron **Spanish:** Pijui Gorgicastaño  
**German:** Orangekehl-Dickichtschlüpfer

**Taxonomy.** *Synallaxis cherriei cherriei* Gyldenstolpe, 1930, Barão Melgaco, Rio Gi-Paraná, Mato Grosso, Brazil.

Previously named *S. rufogularis*, but that name is invalid, as preoccupied. Almost certainly the sister-species of *S. rutilans*, and type specimen was at one time considered to be an aberrant individual of race *amazonica* of that species. Race *saturata* often considered synonymous with *napoensis*, but distinguishable from latter by paler overall plumage. Three subspecies recognized.

#### **Subspecies and Distribution.**

*S. c. napoensis* Gyldenstolpe, 1930 - S Colombia (Putumayo) and E Ecuador (W Sucumbios, W Napo).

*S. c. saturata* Carriker, 1934 - N & C Peru (San Martín, Ayacucho).

*S. c. cherriei* Gyldenstolpe, 1930 - C Amazonian Brazil (Rondônia, N Mato Grosso, and S Pará from lower R Xingu E to Serra dos Carajás).

**Descriptive notes.** 13-14 cm; 15-17 g. Male nominate race has forecrown, face and throat to breast deep rufous-chestnut, hindcrown to back chestnut with strong olive-brown wash (especially on hindcrown), rump and uppertail-coverts dark brown; wing-coverts mostly chestnut, remiges dark fuscous; tail long, graduated, 10 moderately pointed rectrices, slaty blackish; belly and undertail-coverts greyish with olive-brown tinge, occasionally faint pale shaft streaks, flanks slightly darker; iris variable, from ivory to grey to dark brown (source of variation unknown); upper mandible black, lower mandible black to greyish; tarsus and toes dusky olive to

dark horn-coloured to brownish-grey. Differs from very similar *S. rutilans* mainly in lack of dark throat patch. Female is slightly paler than male on throat and belly. Juvenile has upperparts darker and more olivaceous, only faint tinges of rufous on forehead, face, neck, wing-covert margins and breast, whitish throat with faint dusky feather tips, feathers of lower breast and belly faintly margined with brown, lower mandible whitish. Race *napoensis* has more restricted, more sharply defined rufous on forehead, paler margins of primaries, darker belly; *saturata* differs from that in being paler overall, browner above, paler and more orange-rufous on throat and breast, paler grey on belly. **Voice.** Most frequent vocalization "prrrr-préet", "trrr tuuit" or "kra-kü", second note slightly lower and shorter than first, repeated for long periods, often ending with second note alone repeated 4-8 times. Calls described as high-pitched "psiu" and whistled "piwwwh".

**Habitat.** Tropical lowland evergreen forest and secondary forest, often in treefall areas or short forest; details not well understood. Where sympatric with *S. rutilans*, usually occupies more disturbed or open forest or *Guadua* bamboo thickets. At 200-1100 m; to c. 1450 m in Peru.

**Food and Feeding.** Recorded dietary items are Coleoptera, Diptera, Lepidoptera larvae, spiders. Usually forages in pairs, mostly within 1-3 m of ground, also on ground. Arthropods obtained by gleaning and probing dead leaves, small branches, and foliage; also flakes and gleans items from leaf litter.

**Breeding.** No information.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Rare to occasionally fairly common, but has patchy distribution and everywhere very local; few known localities. Occurs in Cuyabeno Reserve, in Ecuador, and in Cristalino State Park, in Brazil. Colombian and Ecuadorian parts of range have suffered rather extensive deforestation and habitat degradation and fragmentation, mainly through road-building associated with oil exploration, and extensive areas of its habitat in Peru have been cleared for agriculture and logging, with subsequent human colonization. Significant percentage of forest in SC Brazil (Mato Grosso, Rondônia) had already disappeared by early 1990s, mainly because of highway construction.

**Bibliography.** Aleixo *et al.* (2000), Angehr & Aueca (1997), Anon. (2003g), Begazo *et al.* (2001), Bond (1945), Carriker (1934), Collar & Andrew (1988), Collar *et al.* (1992), Cory & Hellmayr (1925), Graves & Zusi (1990), Gyldenstolpe (1930a), Hilty & Brown (1986), Negret (2001), Oren & da Silva (1987), Parker *et al.* (1982), Pinto (1978), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stotz *et al.* (1996), Terborgh & Weske (1969), Wege & Long (1995), Zimmer, J.T. (1936b), Zimmer, K.J., Parker *et al.* (1997).

## 83. Rufous Spinetail

### *Synallaxis unirufa*

**French:** Synallaxe roux **German:** Rötlichbrauner Dickichtschlüpfer **Spanish:** Pijui Rufo

**Taxonomy.** *Synallaxis* [sic] *unirufus* Lafresnaye, 1843, Colombia = "Bogotá".

Forms a superspecies with *S. castanea* and *S. fusciorufa*; all three have sometimes been considered conspecific, but substantial vocal differences documented and reciprocal playback trials reveal pronounced vocal discrimination. Birds in Cajamarca (N Peru), duller and less rufous than any others, apparently represent an undescribed race. Four subspecies recognized.

#### **Subspecies and Distribution.**

*S. u. munoztebari* Phelps, Sr. & Phelps, Jr., 1953 - Perijá Mts of NE Colombia and NW Venezuela.

*S. u. meridana* Hartert & Goodson, 1917 - Andes of W Venezuela (Trujillo S to Táchira) and NC Colombia (extreme NW part of E range in Norte de Santander).

*S. u. unirufa* Lafresnaye, 1843 - Andes of Colombia (S possibly from Chocó in W range, from Antioquia in C, and in Cundinamarca and W Casanare in E) and Ecuador (on W slope S only to W Cotopaxi).

*S. u. ochrogaster* J. T. Zimmer, 1935 - Peruvian Andes from Amazonas S to N Cuzco (Cordillera Vilcabamba).

**Descriptive notes.** 16-18 cm; 17-21 g. Relatively large and uniformly brightly coloured *Synallaxis*. Nominative race is almost entirely bright reddish rufous; forehead slightly paler, loreal area sooty blackish, concealed bases of feathers in centre of throat blackish; tail long, graduated, 10 rectrices with shafts slightly stiffened, tips pointed, outer webs slightly disintegrated; iris dark brown to dark reddish-brown; bill black, base of lower mandible sometimes grey to silvery or pale fleshy pink; tarsus and toes grey to dark grey. Sexes alike. Juvenile has brown upperparts, head sometimes tinged olivaceous, underparts paler than adult, darkest on breast. Race *meridana* is paler, black bases of throat feathers more visible, tail slightly longer; *munoztebari* is also paler, no black on throat, faint buff supercilium and forehead; *ochrogaster* is palest of all below, especially in centre of belly. **Voice.** Most frequent vocalization a shrill

“kweeék”, “ku-kweeék” or rising “kwee”, repeated at intervals of 1-4 seconds, often for long periods. Call “jip”; alarm a low “churr”.

**Habitat.** Montane evergreen forest and elfin forest; undergrowth and edge of humid cloudforest, often in *Chusquea* bamboo thickets, sometimes in tall second growth. Mainly 1700-3700 m, locally down to 1200 m.

**Food and Feeding.** Arthropods. Usually in pairs, occasionally in mixed-species flocks. Gleans items from foliage and small branches within 1-2 m of ground, occasionally higher, to 4 m.

**Breeding.** Fledglings in Apr in Colombia. Presumably monogamous. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout range. Occurs in Guaramacal National Park, in Venezuela, Munchique National Park, in Colombia, and Podocarpus National Park, in Ecuador. Rather poorly known spinetail.

**Bibliography.** Cory & Hellmayr (1925), Cuervo & Delgado (2001), Graves (1985), Hilty (2003a), Hilty & Brown (1983, 1986), Meyer de Schauensee (1959), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Phelps & Phelps (1953a), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman (1994), Salaman *et al.* (1999), Stotz *et al.* (1996), Vaurie & Schwartz (1972), Zimmer (1935b, 1936b).

84. Black-throated Spinetail

*Synallaxis castanea*

**French:** Synallaxe de Vaurie    **German:** Mirandadickichtschlüpfer    **Spanish:** Pijui Gorginegro  
**Other common names:** Chestnut Spinetail

**Taxonomy.** *Synallaxis castanea* P. L. Selater, 1956, near Caracas, Venezuela.

Forms a superspecies with *S. unirufa* and *S. fusciorufa*; all three have sometimes been considered conspecific, but substantial vocal differences documented and reciprocal playback trials reveal pronounced vocal discrimination. Monotypic.

**Distribution.** Coastal range of N Venezuela from Aragua E to Miranda (E to Caracas area).

**Descriptive notes.** 16-18 cm. Relatively large and uniformly bright *Synallaxis*. Plumage is almost wholly bright rufescent, chin paler, but throat solidly black; tail long, graduated, usually 8 rectrices (sometimes 10), shafts slightly stiffened, tips only slightly pointed; iris dark reddish-brown; bill blackish; tarsus and toes blue-grey. Differs from *S. unirufa* in brighter coloration, black throat, slightly different tail structure (only 8 rectrices, which broader and blunter, and not disintegrated). Sexes alike. Juvenile is more brownish and duller than adult, throat patch dull and indistinct, feathers of head and underparts usually faintly edged dusky.

**VOICE.** Song a rapid “ke-che-che-che-che” followed immediately by louder “ker-chéé-chéé”; often as duet. Call a loud “ki-kik”.

**Habitat.** Montane evergreen forest, secondary forest; undergrowth and edge of cloudforest and second growth; commonly in shrubby thickets at forest edge and along roadsides, and occasionally in *Chusquea* bamboo. At 1300-2200 m.

**Food and Feeding.** Little known. Usually seen in pairs. Presumably gleans arthropods from foliage and small branches within 1-2 m of ground.

**Breeding.** Season Apr-Jul. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Cordillera de la Costa Central EBA. Fairly common, but has very small range. Occurs in Henri Pittier and Macarao National Parks.

**Bibliography.** Cory & Hellmayr (1925), Hilty (2003a), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vaurie & Schwartz (1972).

85. Rusty-headed Spinetail

*Synallaxis fusciorufa*

**French:** Synallaxe des Santa Marta    **Spanish:** Pijui de Santa Marta  
**German:** Rotkopf-Dickichtschlüpfer  
**Other common names:** Santa Marta Spinetail

**Taxonomy.** *Synallaxis fusco-rufa* P. L. Selater, 1982, San Sebastián, 7000 feet [c. 2130 m], Sierra Nevada de Santa Marta, Colombia.

Forms a superspecies with *S. unirufa* and *S. castanea*; all three have sometimes been considered conspecific, but substantial vocal differences documented and reciprocal playback trials reveal pronounced vocal discrimination. Monotypic.

**Distribution.** Santa Marta Mts of N Colombia.

**Descriptive notes.** 16-18 cm; 15-17 g. Plumage is bright reddish rufous, apart from dark loreal area, dull greyish-olive back, olive flanks, concealed blackish bases of throat feathers; tail long, graduated, 10 rectrices with shafts slightly stiffened, tips pointed, outer webs slightly disintegrated, duller rufous; iris reddish-brown; upper mandible black, lower mandible blue-grey; tarsus and toes grey to blue-grey. Differs from *S. unirufa* in back colour, less contrasting loreal area, black bases of throat feathers less extensive, tail duller. Sexes alike. Juvenile has much duller crown, underparts edged tawny-olive, faint barring on belly.

light brown eyes, yellowish-pink lower mandible. **VOICE.** Most frequent vocalization a nasal “dit-du” c. 1 second long, final note descending and lower-pitched, often repeated at intervals of 1-4 seconds for long periods.

**Habitat.** Edge of montane evergreen forest, overgrown clearings and second-growth scrub; mostly 2000-3000 m, locally down to 760 m.

**Food and Feeding.** Arthropods. Forages usually in pairs. Gleans items from foliage and small branches within 1-2 m of ground.

**Breeding.** No information other than birds with large gonads in Jan-Jun.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Santa Marta Mountains EBA. Fairly common to common, but has very small range. Has suffered extensive habitat loss, and agricultural expansion, logging and burning continue to pose a threat.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Orejuela (1985), Remsen (2003a), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Carriker (1922b).

## 86. Rufous-breasted Spinetail

### *Synallaxis erythrothorax*

**French:** Synallaxe à poitrine rousse

**Spanish:** Pijui Centroamericano

**German:** Rotbrust-Dickichtschlüpfer

**Other common names:** Rufous-breasted Castlebuilder

**Taxonomy.** *Synallaxis erythrothorax* P. L. Slater, 1855, Honduras.

Probably forms a superspecies with *S. brachyura* and perhaps *S. tithys*; abruptly replaced by former in N Honduras, and their nests are remarkably similar. Some tendency for N birds of nominate race to have darker and more uniform central belly, but extensive overlap with others farther S; proposed race *furtiva*, described from Caribbean lowlands of Mexico, is not diagnosable. Two subspecies recognized.

#### Subspecies and Distribution.

*S. e. erythrothorax* P. L. Slater, 1855 - Caribbean slope from SE Mexico (S Veracruz and Yucatán Peninsula S to N Oaxaca and Tabasco) S to Guatemala, Belize and NW Honduras.

*S. e. pacifica* Griscom, 1930 - Pacific lowlands of SW Mexico (S Chiapas), Guatemala and El Salvador.

**Descriptive notes.** 14-16 cm; 15-19 g. Mid-sized *Synallaxis* with unusual plumage. Nominant race has dark sooty brownish face, uniform dark brownish-grey crown to back, brown rump and uppertail-coverts; wings dark rufous except for dusky tips of remiges; tail long, strongly graduated, 10 rectrices with stiffened shafts, pointed and somewhat disintegrated (possibly only through wear) at tip, distal 1-2 mm almost without barbs and giving "spiny" appearance, same colour as rump; throat blackish, feathers of chin and upper throat with whitish shaft streaks and margins creating vaguely striped appearance; breast and

sides dark rufous, whitish belly mottled greyish, flanks and undertail-coverts rich brown; iris dark red to reddish-brown or brown; bill black to dark grey, sometimes grey base of lower mandible; tarsus and toes grey, blue-grey or dark grey. Sexes alike. Juvenile has throat patch greyish and less distinct, chest dusky brown, iris brown, upper mandible dark brown, lower mandible pale yellowish-brown. Race *pacifica* has lower throat grey, not blackish, belly greyer and more uniform, rufous areas slightly paler, tail brighter, redder. Voice. Song a rapid, rough chatter with 1-3 introductory notes, "chree, ree, reu-reu-reu-reu". Main contact call a nasal "whit-chew", first note usually repeated 2-4 times, also described as "zhee-zhee-zhee-zhoo" with first 3 notes ascending and final one lower and slurred; sharp "cheurr" and nasal "kyow" also given.

**Habitat.** Secondary forest, second-growth scrub, tropical lowland evergreen forest edge; to 750 m.

**Food and Feeding.** Little known. Recorded dietary items are Lepidoptera larvae, spiders, and some fruit. Usually forages in pairs in understorey. Probably gleans arthropods from foliage and small branches within 1-2 m of ground.

**Breeding.** Eggs in May-Jun in Guatemala, Jun and Aug in El Salvador and Aug-Sept in Honduras. Monogamous. Nest a bulky mass c. 40 × 70 cm, of twigs and small sticks, often thorny ones, some up to 43 cm long, horizontal entrance tube 30-40 cm long usually turns upwards at opening (forming short turret), reptile skins prominent, especially on bottom of entrance tube, spherical inner chamber c. 13-15 cm in diameter and roofed with coarse plant material, floor lined with grass, small twigs, or soft or pubescent green leaves (often of *Solanum*) and occasionally snake and lizard skins; placed in dense bush or small tree, often among vines, 1.5-6 m above ground, and supported on main branch by strong lateral or parallel branches. Clutch 2-4 eggs; both sexes incubate, period 17-18 days; both also feed nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. The only furnariid restricted to N Middle America. Fairly common to common in most of range. May benefit from moderate forest fragmentation, but evidently does not inhabit deforested areas.

**Bibliography.** Anon. (1988a), Binford (1989), Cory & Hellmayr (1925), Dickey & van Rossem (1938), England (2000), Gordon & Ornelas (2000), Howell & Webb (1995a), Lea (1951), Lowery & Dalquest (1951), Monroe (1968), Paynter (1955), Remsen (2003a), Ridgely & Tudor (1994), Russell (1964), Skutch (1969c, 1985, 1987), Stotz *et al.* (1996), Wetmore (1943).

## 87. Slaty Spinetail

### *Synallaxis brachyura*

**French:** Synallaxe ardoisé

**German:** Graurücken-Dickichtschlüpfer

**Spanish:** Pijui Pizarroso

**Other common names:** Grey-throated/Sooty Spinetail, Sooty Castlebuilder

**Taxonomy.** *Synallaxis brachyura* Lafresnaye, 1843, Colombia = "Bogotá".

Probably forms a superspecies with *S. erythrothorax* and perhaps *S. tithys*; abruptly replaces former in N Honduras, and their nests are remarkably similar. Proposed race *chapmani* (S Central America to NW Ecuador) described as like *nigrofumosa* but with rump slightly browner and crown, wings and underparts slightly paler, but variation evidently clinal, and individual specimens not diagnosable. Named taxon *jaraguana* from E Brazil (Goias), described as a race of present species, was based on misidentified specimens of *S. hypospodia*. Four subspecies tentatively recognized.

#### Subspecies and Distribution.

*S. b. nigrofumosa* Lawrence, 1865 - NC Honduras S to Panama and NW Colombia S to NW Ecuador (S to N Guayas).

*S. b. brachyura* Lafresnaye, 1843 - N Colombia (Antioquia E to Magdalena Valley).

*S. b. cauae* Chapman, 1914 - C Colombia (Cauca Valley).

*S. b. griseonucha* Chapman, 1923 - SW Ecuador (S from Guayas and Azuay) S to extreme NW Peru (Tumbes).

**Descriptive notes.** 14-16 cm; 16-21 g. One of the darkest species in genus. Nominant race has deep rufous-chestnut crown and nape, greyish supercilium, darker grey rest of head, dark sooty-brown

olive-grey, grey or blue-grey. Sexes alike. Juvenile lacks contrasting crown colour, has upperparts paler than adult, wing-coverts duller, throat patch less distinct and paler, underparts more olivaceous. Race *nigrofumosa* is darker throughout, crown and wings darker rufous, back darker brown, underparts darker grey; *griseonucha* is slightly paler than previous, especially on underparts; *cauae* has paler crown, greyer back, paler greyish-olive rump and uppertail-coverts. Voice. Song a low "ch-ch-ch-churr-r-r-r", "je-ch-ch-chrrrr" or "chut-chut-chrrrrrrrrrr", slightly descending at end, lasting c. 0.3 seconds, repeated at intervals of 1-2 seconds. Call during foraging "chk"; "chee-ah" also described.

**Habitat.** Second-growth scrub, riparian thickets, and undergrowth at edges of montane evergreen forest and tropical lowland evergreen forest; also overgrown clearings, locally also thorn-scrub, edges of swamps, and gardens. Mainly to 1400 m, locally to 2000 m.

**Food and Feeding.** Dietary items recorded are Coleoptera, Hemiptera, larval Diptera and Lepidoptera, spiders, spider eggs, and seeds. Usually in pairs, foraging from undergrowth down to ground. Gleans arthropods from dead leaves, small branches, foliage, and leaf litter.

**Breeding.** Eggs in Jan-Feb and Apr-Oct in Costa Rica. Monogamous; paired throughout year. Nest a bulky mass c. 20-40 cm high and 40-50 cm long, of twigs and small sticks, often thorny, some as long as 25 cm, reptile skins also regularly incorporated, horizontal entrance tube 30-40 cm long (sometimes two separate tubes), possibly sometimes curved, inner chamber covered by denser thatch, floor lined with pad of soft green or pubescent leaves or fragments (usually of *Solanum*) mixed or bound with spider webbing and occasionally snake and lizard skins; placed in dense bush or small vine-covered tree, usually 0.5-5 m above ground. Clutch 2-3 eggs; incubation by both sexes, period 18-19 days; both also feed chicks, nestling period 17 days; fledglings independent in 30 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in most of range. Occurs in La Planada Nature Reserve and Rio Nambi Natural Reserve, in Colombia. Tolerant of moderate anthropogenic habitat disturbance, and presumably benefits from fragmentation of forest.

**Bibliography.** Anon. (1988a), Chapman (1926), Cook (1996), Cory & Hellmayr (1925), Fjeldsa & Krabbe (1990), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995a), Kirwan & Marlow (1996), Meyer de Schauensee (1951), Miller (1960), Monroe (1968), Parker & Carr (1992), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Pinto (1936, 1978), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Rodner *et al.* (2000), Salaman (1994), Sekercioglu *et al.* (2002), Sick (1993, 1997), Skutch (1969c, 1985, 1987), Slud (1960, 1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Todd & Carriker (1922a), Wetmore (1972), Wiedenfeld *et al.* (1985), Young *et al.* (1998).

## 88. Blackish-headed Spinetail

### *Synallaxis tithys*

**French:** Synallaxe tithys

**German:** Schwarzgesicht-Dickichtschlüpfer

**Spanish:** Pijui Cabecinegro

**Other common names:** Black-faced/Taczanowski's Spinetail

**Taxonomy.** *Synallaxis tithys* Taczanowski, 1877, Lechugal, Tumbes, Peru.

May form a superspecies with *S. erythrothorax* and *S. brachyura*. Monotypic.

**Distribution.** SW Ecuador (S from SW Manabí and C Loja) and extreme NW Peru (Tumbes, N Piura).

**Descriptive notes.** 16-17 cm; 14-18 g. The only *Synallaxis* having a black forecrown. Has front of head black, hindcrown and upper back dark grey, blending to dark brownish rump and uppertail-coverts; wing-coverts tawny-rufous, remiges dark fuscous with rufescent brown edging; tail long, graduated, 8 rectrices pointed towards tips, dark fuscous; chin blackish (faint pale shaft streaks conceal black feather bases when viewed head-on), throat black, malar region grizzled with whitish; underparts grey, becoming paler on belly, olive tinge on flanks and undertail-coverts; iris reddish-brown to grey-brown (source of variation unknown); upper mandible black to dark grey, lower mandible blue-grey to grey; tarsus and toes grey or pale grey to bluish-horn. Sexes alike. Juvenile is more olivaceous, less grey, dark frontal band not well defined, underparts often mottled grey. Voice. Song a short, dry trill, "t-t-t-t-tit", c. 1 second long, often repeated every few seconds.

**Habitat.** Tropical deciduous forest; in undergrowth of deciduous forest, second growth, and adjacent scrub; 50-1100 m.

**Food and Feeding.** Recorded dietary items are Coleoptera, Orthoptera and Hymenoptera. Usually in pairs, rarely in mixed-species flocks. Gleans arthropods from ground and leaf litter, also from foliage and small branches, usually within 2 m of ground.

**Breeding.** Presumably breeds during Jan-Apr wet season; laying apparently in Mar, and juvenile trapped in Aug. Presumably monogamous. Nest a ball of sticks c. 30 cm × 30 cm, placed in vine tangles 3-7 m above ground. No further information.

**Movements.** Resident; some suggestion of local elevational movements.

**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in Tumbesian Region EBA. Uncommon to common. In Ecuador, fairly common in Arenillas Military Reserve, uncommon in Machabilla National Park and rare in Cerro Blanco Forest Reserve; present in Loma Alta Ecological Reserve, in SW Ecuador. Common to fairly common in Tumbes National Reserve, in NW Peru. Estimated total population 2500-10,000 individuals; declining as a result of habitat destruction. Population of this species has been greatly reduced by deforestation, and by degradation of remaining deciduous forest through overgrazing and cutting. Surveys required in order to assess its current population, and to determine its ability to survive in heavily degraded habitats. Effective protection of localities where it occurs is essential.

**Bibliography.** Balchin (1996), Becker *et al.* (2000), Best & Clarke (1991), Best, Clarke *et al.* (1993), Best, Heijnen & Williams (1997), Bond (1945), Chapman (1926), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cook (1996), Cory & Hellmayr (1925), Granizo (2002), Lowen (1998), Parker & Carr (1992), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Pople *et al.* (1997), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Walker (2002), Wege & Long (1995), Wiedenfeld *et al.* (1985).

## 89. White-bellied Spinetail

### *Synallaxis propinqua*

**French:** Synallaxe à ventre blanc

**Spanish:** Pijui Ventriblanco

**German:** Flussinsel-Dickichtschlüpfer

**Taxonomy.** *Synallaxis propinqua* Pelzeln, 1859. Rio Madeira below the junction of the Mahissy (= Rio Igarapé Maici), Rondônia, Brazil. No obvious close relatives, Monotypic.

**Distribution.** French Guiana (R Oyapock), and E Ecuador (lower R Aguarico, R Napo, R Pastaza), NE Peru (R Napo, R Amazon, R Ucayali), extreme SE Colombia (islands in R Amazon), Brazil (locally along R Amazon E to R Tocantins, also on lower R Branco, middle R Juruá, upper R Madeira) and NE Bolivia (lower R Beni).

**Descriptive notes.** 15-16 cm; 18-22 g. Typical *Synallaxis* but with noticeably longer bill. Has almost plain light greyish-brown face with indistinct paler supercilium, dark eyeline; crown and back to uppertail-coverts greyish-brown; wing-coverts rufous, remiges duller; tail long, graduated, 10 rectrices sharply pointed, dull rufous; chin greyish-white, throat black with faint greyish fringes giving frosted look (viewed from certain angles, especially head-on, pale margins nearly obliterate black of throat, whereas from other angles throat appears solidly black); breast dull grey, belly whitish, flanks brownish-grey, to light brown to white (source of variation unknown); upper mandible black to dark grey, lower mandible grey, sometimes blackish tip; tarsus and toes grey-green to olive-grey. Sexes alike. Juvenile has paler upperparts and much paler underparts washed buff, throat patch concealed, no rufous in wings. **Voice.** Song a nasal, mechanical "eh. eh-hhhhhh" or "ch-rr-r-r-r-r-r-r", c. 1-5 seconds long, sometimes lengthened into descending trill reminiscent of trills of *Laterallus* rails. Call during foraging "kr-krreenh" or short series of similar notes.

**Habitat.** River-island scrub; dense early-successional vegetation, especially *Tessaria* thickets, on young to middle-aged islands in major rivers, usually with tall grass or young *Gynerium* cane mixed with low bushes and grass. To 300 m, rarely 400 m.

**Food and Feeding.** Arthropods. Usually in pairs. Gleans items mainly from small branches, also foliage, within 1-2 m of ground; rarely, descends to ground. Recorded also as making short sally into air.

**Breeding.** No information.

**Movements.** Apparently resident. Seasonal flooding of habitat may force local movements, but this not yet studied.

**Status and Conservation.** Not globally threatened. Fairly common to common within appropriate habitat. Patchy and linear nature of its distribution, however, means that total population is rather small, despite its large geographical range.

**Bibliography.** Cory & Hellmayr (1925), Pacheco (1995), Parker *et al.* (1982), Pearman (1993b), Pinto (1978), Remsen (2003a), Remsen & Parker (1983), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg, G.H. (1990), Sick (1993, 1997), Stotz *et al.* (1996), Todd (1948b), Tostain *et al.* (1992), Zimmer (1936b).

## 90. McConnell's Spinetail

### *Synallaxis macconnelli*

**French:** Synallaxe de McConnell

**Spanish:** Pijui de McConnell

**German:** Östlicher Dunkeldickichtschlüpfer

**Taxonomy.** *Synallaxis macconnelli* Chubb, 1919. Mount Roraima, Bolívar, Venezuela.

Forms a superspecies with *S. moesta* and *S. cabanisi*, and all have often been treated as conspecific. Juvenile plumage differs from that of the other two. Race *yavii*, based on a single specimen from locality near range of nominate, is regarded by many as of dubious validity, e.g. possibly a subadult plumage of latter race; description, however, indicates that it is distinctive; considered better to retain it as a valid taxon, pending further study. Proposed race *griseipectus*, described from Mt Ptari-tepui, in Bolívar (Venezuela), is regarded as not diagnosable. Scientific name of species was based on misspelling, as species was named after F. V. McConnell, but original version stands. Three subspecies recognized.

**Subspecies and Distribution.**

*S. m. yavii* Phelps, Jr. & Phelps, Jr., 1947 - Cerro Yavi, in S Venezuela (N Amazonas).

*S. m. macconnelli* Chubb, 1919 - SE Venezuela (tepui region of Bolívar, and Cerro de la Neblina in S Amazonas) and N Brazil (Cerro de la Neblina, Serra Parima).

*S. m. obscurior* Todd, 1948 - Surinam, French Guiana and extreme NE Brazil (Amapá).

**Descriptive notes.** 15-17 cm; 18-20 g. Rather large, dark and comparatively short-tailed spinetail. Nominative race has thin pale postocular line, greyish face; crown and nape dark rufous, back to uppertail-coverts dark olive-brown; wings mostly rufous-chestnut, distal portions of remiges fus-

couous brown; tail graduated, 8 rectrices, shafts thickened, tips pointed and slightly disintegrated, dull dark chestnut; chin and throat feathers blackish with some greyish-white edges; underparts brownish-grey, slightly paler in centre of belly, faintly tinged browner on flanks; iris chestnut; bill black, whitish base of lower mandible; tarsus and toes olive. Sexes alike. Juvenile has upperparts like adult, including rufous crown, but slightly paler and browner, throat faintly barred grey and white, breast and belly distinctly browner than adult. Race *yavii* described as much paler below than nominate, pale olive rather than dark grey (no indication of barring that would suggest juvenile plumage); *obscurior* is generally greyer and darker.

**Voice.** Song a weak, hoarse, low-pitched "kir-r-r-r-r-r, kik", final note much softer, sometimes introduced with "churr" note.

**Habitat.** Tropical lowland evergreen forest edge, montane evergreen forest edge, secondary forest; dense undergrowth at edge of tropical and lower montane forest; riverine forest locally in French Guiana. From 1000 m to 1900 m (nominate); 1000 m in S Venezuela (*yavii*); race *obscurior* ranges to much lower elevations, down to near sea-level.

**Food and Feeding.** Little known. Usually seen in pairs. Probably gleans arthropods from foliage and small branches within 1-2 m of ground.

**Breeding.** Nest a ball of sticks with lateral entrance tube, placed 3-4 m up in shrub. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common, but local in distribution. Estimated density at two forest sites in French Guiana was 2-5/km<sup>2</sup>. Evidently a true forest species which, unlike many *Synallaxis* spinetails, does not occur in heavily cut-over areas. Protection of adequate forest cover should ensure its survival.

**Bibliography.** Barrowclough *et al.* (1995), Chapman (1931), Cory & Hellmayr (1925), Dick *et al.* (1984), Haverschmidt & Mees (1994), Hilty (2003a), Mayr & Phelps (1967), Mees (1987), Novaes (1974, 1980), Phelps, W.H. & Phelps (1947), Phelps, W.H. Jr. (1972), Ridgely & Tudor (1994), Rodner *et al.* (2000), Thiollay (1986), Tostain *et al.* (1992), Vaurie (1971d), Zimmer & Phelps (1948).

## 91. Dusky Spinetail

### *Synallaxis moesta*

**French:** Synallaxe obscure

**German:** Westlicher Dunkeldickichtschlüpfer

**Spanish:** Pijui Oscuro

**Other common names:** Selater's Spinetail; Brown-tailed Spinetail (*brunneicaudalis*)

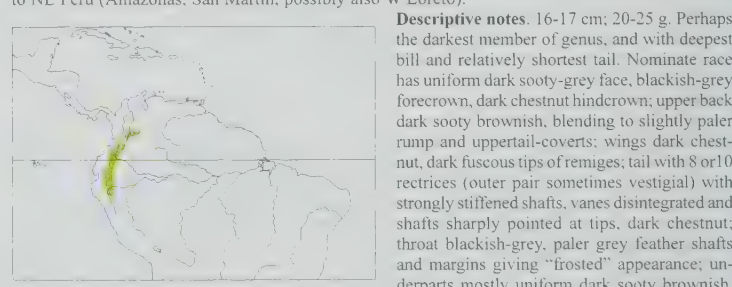

**Taxonomy.** *Synallaxis moesta* P. L. Selater, 1856. "Bogotá". Forms a superspecies with *S. macconnelli* and *S. cabanisi*, and all have often been treated as conspecific. Differs from both of those in tail structure. Race *brunneicaudalis* was formerly treated as a separate species. Three subspecies recognized.

**Subspecies and Distribution.**

*S. m. moesta* P. L. Selater, 1856 - foothills of E Andes in C Colombia (S Casanare S to NW Meta).

*S. m. obscura* Chapman, 1914 - E Andean foothills in S Colombia (Cauquetá, Putumayo).

*S. m. brunneicaudalis* Selater, 1858 - foothills of E Andes from extreme S Colombia (SE Nariño) S to NE Peru (Amazonas, San Martín, possibly also W Loreto).

**Descriptive notes.** 16-17 cm; 20-25 g. Perhaps the darkest member of genus, and with deepest bill and relatively shortest tail. Nominative race has uniform dark sooty-grey face, blackish-grey forecrown, dark chestnut hindcrown; upper back dark sooty brownish, blending to slightly paler rump and uppertail-coverts; wings dark chestnut, dark fuscous tips of remiges; tail with 8 or 10 rectrices (outer pair sometimes vestigial) with strongly stiffened shafts, vanes disintegrated and shafts sharply pointed at tips, dark chestnut; throat blackish-grey, paler grey feather shafts and margins giving "frosted" appearance; underparts mostly uniform dark sooty brownish,

slightly browner on flanks; iris rufous to brown; upper mandible black to slate, lower mandible blue-grey to light grey, sometimes dark tip; tarsus and toes greenish-grey to greyish-olive. Sexes alike. Juvenile lacks contrasting crown colour, has wing-coverts tipped dusky brownish, throat with faint grey and white barring, underparts more greyish, faintly mottled darker. Race *brunneicaudalis* is darker than nominate, mostly dark grey and more uniformly coloured below; *obscura* is even darker than previous, browner on back, tail and underparts, pale margins of throat feathers more restricted. **Voice.** Little known; low nasal chattering, "rha-a-a-a-a-a-a", may be call or song.

**Habitat.** River-edge forest edge, tropical lowland evergreen forest edge, secondary forest; dense undergrowth at edge of usually hilly tropical forest, and second growth, sometimes bamboo thickets; 250-1350 m.

**Food and Feeding.** Little known. Usually in pairs. Probably gleans arthropods from foliage and small branches within 1-2 m of ground.

**Breeding.** No information other than birds with enlarged gonads in Jun in Colombia.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon and local. Evidently a true forest species, not found in heavily cut-over areas. Occurs within a narrow elevational band in an altitudinal zone that is often under intense pressure from agriculture.

**Bibliography.** Balchin & Toyne (1998), Cadena, Alvarez *et al.* (2000), Chapman (1926), Cory & Hellmayr (1925), Hilty (2003a), Hilty & Brown (1986), Mayr & Phelps (1971), Mees (1987), Parker *et al.* (1982), Peña (1997), Pinto (1978), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman *et al.* (1999), Schulenberg (2002), Sick (1993, 1997), Vaurie (1971d), Zimmer (1936b).

## 92. Cabanis's Spinetail

### *Synallaxis cabanisi*

**French:** Synallaxe de Cabanis

**German:** Rostscheitel-Dickichtschlüpfer

**Spanish:** Pijui de Cabanis

**Taxonomy.** *Synallaxis cabanisi* Berlepsch and Leverkühn, 1890, Chanchamayo Valley, Junín, Peru. Forms a superspecies with *S. macconnelli* and *S. moesta*, and all have often been treated as conspecific. Differs from former in juvenile plumage and from latter in tail structure. Racial identity of disjunct population in Brazil (N Mato Grosso) uncertain; tentatively assigned to nominate race. Two subspecies recognized.

**Subspecies and Distribution.**

*S. c. cabanisi* Berlepsch & Leverkühn, 1890 - Andean foothills in C & S Peru (Huánuco S to Puno, possibly also W Ucayali); probably also C Brazil (N Mato Grosso).

*S. c. fulviventris* Chapman, 1924 - foothills of Andes in N Bolivia (La Paz, W Beni, Cochabamba).

**Descriptive notes.** 16-18 cm; 16-24 g. Relatively large *Synallaxis* with typical plumage pattern but comparatively short tail. Nominate race has sooty grey-brown face with indistinct ochraceous chestnut postocular streak; forehead to hindneck dark rufous-chestnut, back to uppertail-coverts dark brown; wings rufous-chestnut, distal portions of remiges fuscous brown; tail graduated, 10 rectrices with thickened shafts, pointed and slightly disintegrated at tips, dull chestnut; chin and side of throat brownish-grey, blackish feathers of throat centre with extensive greyish margins (almost completely conceal black bases in head-on view), greyish-white malar region sharply defined; brownish-grey below, slightly paler in centre of belly, faintly tinged brown on flanks; iris reddish-brown to brown; upper mandible black, lower mandible silver to grey, sometimes blackish tip; tarsus and toes olive-grey to yellowish-grey. Distinguished from similar *S. moesta* mainly by rufous forehead, sharply defined malar region, whitish margins of throat feathers usually surrounding tips, giving slightly more barred than faintly streaked impression. Sexes alike. Juvenile lacks contrasting crown colour, has throat faintly barred grey and white, underparts more greyish, faintly mottled darker. Race *fulviventris* is smaller, has whiter throat and much paler underparts, breast tawny-olive, belly centre buff, not greyish. VOICE. Low nasal "nyap", often doubled, probably a call; song not described.

**Habitat.** Tropical lowland evergreen forest edge, secondary forest, river-edge forest; dense undergrowth at edge of usually hilly tropical forest, also second growth; often in *Guadua* bamboo or *Gynerium* cane thickets along rivers. At 200-350 m.

**Food and Feeding.** Little known. Usually found in pairs. Probably gleans arthropods from foliage and small branches within 1-2 m of ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common, but local in distribution. A poorly known species. Isolated population in Brazil only recently discovered, in 1997.

**Bibliography.** Alonso *et al.* (2001), Angehr & Auca (1997), Cory & Hellmayr (1925), Foster *et al.* (1994), Mayr & Phelps (1967), Mazar Barnett, Kirwan & Tobias (1998), Mees (1987), Parker, Parker & Plenge (1982), Parker, Stotz & Fitzpatrick (1997), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Sick (1993, 1997), Terborgh & Weske (1969), Terborgh *et al.* (1984), Vaurie (1971d), Zimmer, J.I. (1936b), Zimmer, K.J., Parker *et al.* (1997).

## 93. Marañon Spinetail

### *Synallaxis maranonica*

**French:** Synallaxe du Marañon

**Spanish:** Pijui del Marañón

**German:** Marañon-Dickichtschlüpfer

**Taxonomy.** *Synallaxis maranonica* Taczanowski, 1879, Huajango, Rio Marañón, Amazonas, Peru. Forms a superspecies with *S. gujanensis* and *S. albilora*. Often considered a race of former, but differs in plumage sufficiently that some authors have considered it more closely related to others of genus. Monotypic.

**Distribution.** Marañón Valley in N Peru (N Cajamarca, NW Amazonas) and extreme S Ecuador (S Zamora-Chinchipe).

**Descriptive notes.** 14-16 cm; 16-17 g. Long-billed, plain, dark *Synallaxis*. Has dull dark brownish-grey forehead and face; crown and upper back dull dark greyish-brown, blending to more rufescent brown rump and uppertail-coverts; wings dark rufous, remiges with dark fuscous tips; tail graduated, 10 rectrices, unusually blunt, dark rufous; throat pale greyish, blending to darker brownish-grey breast, belly slightly paler, flanks tinged olive-brown; iris brown; upper mandible black to dark grey, lower mandible blue-grey; tarsus and toes grey to olive. Sexes alike. Juvenile has faintly darker scalloping on breast and belly, pinkish-yellow

lower mandible. VOICE. Song a nasal "kiweeu, keeetu", repeated at intervals of 5-10 seconds, thus more slowly paced than voice of *S. gujanensis*.

**Habitat.** Gallery forest and secondary forest; undergrowth of deciduous woodland, often along rivers; locally at edge of more humid forest and regenerating clearings. At 500-1250 m.

**Food and Feeding.** Arthropods. Usually forages in pairs. Gleans food items from ground, foliage, and small branches within 1-2 m of ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Marañón Valley EBA. Uncommon to fairly common within its tiny range; difficult to observe, and possibly overlooked. Population estimated to be greater than 10,000 individuals, but declining owing to habitat destruction. Not known to occur in any formally protected area. Woodland in the Marañón Valley has suffered from long-term cultivation of land; remaining habitat is also at risk from the widespread planting of oil palms (*Elaeis guineensis*) and logging activities.

**Bibliography.** Begazo *et al.* (2001), Collar *et al.* (1992), Cory & Hellmayr (1925), Dinerstein *et al.* (1995), Parker *et al.* (1982), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884).

## 94. Plain-crowned Spinetail

### *Synallaxis gujanensis*

**French:** Synallaxe de Cayenne

**Spanish:** Pijui Coronipardo

**German:** Braunkappen-Dickichtschlüpfer

**Other common names:** Guianan Spinetail

**Taxonomy.** *Motacilla gujanensis* J. F. Gmelin, 1789, Guiana = "Cayenne".

Forms a superspecies with *S. maranonica* and *S. albilora*, and all three are often treated as conspecific. S races, geographical variation in which is step-clinal, are vocally closer to latter species and become more like it in plumage as their ranges approach each other. Thorough analysis of species limits required. Further, boundaries of various races uncertain; *inornata* intergrades with *certhiola* in Beni Valley (Bolivia), and birds from lower R Purús E to lower R Madeira (Brazil) are evidently intermediate between former and nominate; rigorous analysis may reveal widespread clinal variation that would render division into races impossible. Six subspecies recognized.

**Subspecies and Distribution.**

*S. g. columbiana* Chapman, 1914 - E Colombia (W Meta S to Putumayo).

*S. g. gujanensis* (J. F. Gmelin, 1789) - E & S Venezuela (E Monagas S to Bolívar and N Amazonas), the Guianas and N & E Brazil (Amazonas and N Roraima E to Amapá and, S of R Amazon, from Pará and N Mato Grosso E to Maranhão and N Goiás).

*S. g. huallagae* Cory, 1919 - E Ecuador (Sucumbios, Napo), SE Colombia (Amazonas), E Peru (Amazonas S to E Cuzco and Madre de Dios) and N Bolivia (Pando).

*S. g. canipileus* Chapman, 1923 - SE Peru (W Cuzco, Puno).

*S. g. inornata* Pelzeln, 1856 - WC Brazil (Amazonas S of R Amazon) S to NE Bolivia (E Beni).

*S. g. certhiola* Todd, 1916 - E Bolivia (S Beni S to Santa Cruz).

**Descriptive notes.** 15-17 cm; 13-22 g. One of the duller and plainest *Synallaxis*. Nominat race has mostly plain dull greyish-brown face, hint of greyish-buff supercilium; crown and back to uppertail-coverts dull brownish, slightly darker and greyer on forecrown; wings dark rufous, duller tips of remiges; tail graduated, 10 rectrices, tips sharply pointed, shafts slightly stiffened, dark rufous; throat whitish, blending to brownish breast, flanks and undertail-coverts, belly paler; iris brown to light brown; upper mandible blackish, lower mandible grey to pale grey, sometimes with blackish tip; tarsus and toes olive-grey to

greenish-yellow, or blue-grey. Sexes alike. Juvenile has faint dusky scalloping on breast. Race *columbiana* has much whiter underparts than nominate, with greyer, less tawny, flanks; *huallagae* is darker and greyer, flanks olivaceous; *canipileus* resembles previous, but crown and underparts greyer, contrasting more with back, wings and tail slightly paler; *inornata* has upperparts a richer brown, especially on crown, auriculars more buffy, underparts much brighter rusty; *certhiola* is like previous, but auriculars more greyish, hindcrown greyer, back paler and more olivaceous (less rufescent), wings and tail paler, underparts conspicuously paler, centre of belly buffy white, underwing-coverts lighter ochraceous. VOICE. Song a sharp "téw, hu" or "kéék, uh", second note much lower-pitched than first, distinct pause between the two, often repeated for long periods; race *inornata* song differs, "chew, chu-weet" or "pyeeew, pip-sweet", first note more downward-inflected and third note upward-inflected, thus more like that of *S. albilora*. Also gives short trill followed by querulous note, "ttttt-cheeoo".

**Habitat.** River-edge forest, secondary forest, gallery forest; undergrowth in riverine habitats, from tall scrub dominated by *Gynerium* cane and undergrowth in tall *Cecropia* woodland on old river islands to edges of tall *varzea* forest; also in regenerating clear-cuts with dense bushy vegetation, and plantations. To 1200 m; below 600 m in Venezuela.

**Food and Feeding.** Arthropods: Orthoptera and larvae of Lepidoptera recorded. Usually in pairs. Gleans items from small branches, foliage and grass within 1-2 m of ground; also on ground.

**Breeding.** Eggs in Jan, Mar, May-Sept and Dec in Surinam. Presumably monogamous. Nest a globular mass c. 65 cm long × 25 cm × 25 cm, made of sticks, entrance hole to horizontal tunnel at long end, placed 1-2 m above ground in low, dense vegetation; territory size in SE Peru c. 2 ha. Clutch 2-3 eggs. Nests often parasitized by Striped Cuckoo (*Tapera naevia*) in Surinam.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in most of its range. Rather local in Venezuela.

**Bibliography.** Angehr & Auca (1997), Barnett *et al.* (2002), Bond (1945), Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1925), Davis (1993), Foster *et al.* (1994), Graves & Zusi (1990), Guerrero & Arambiza (2001), Gyldestolpe (1945a, 1945b), Haverschmidt & Mees (1994), Hayes (1995), Hayes *et al.* (1990), Hellmayr (1907d), Hilty (2003a), Hilty & Brown (1986), Oren & Parker (1997), Parker & Bailey (1991), Parker *et al.* (1982), Pinto (1953), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1995, 1997), Rodner *et al.* (2000), Romero (1978), Rosenberg, G.H. (1990), Sick (1993, 1997), da Silva, Lima & Marceliano (1990), da Silva, Oren *et al.* (1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh & Weske (1969), Terborgh *et al.* (1984), Tostain *et al.* (1992), Willis & Oniki (1990), Zimmer, J.T. (1936b), Zimmer, K.J., Parker *et al.* (1997).

## 95. White-lored Spinetail

### *Synallaxis albilora*

**French:** Synallaxe ocre

**German:** Weißzügel-Dickichtschlüpfer

**Spanish:** Pijui Ocráceo

**Other common names:** Ochre-breasted Spinetail; Araguaia Spinetail (*simoni*)

**Taxonomy.** *Synallaxis albilora* Pelzeln, 1856, Cuiabá, Mato Grosso, Brazil.

Forms a superspecies with *S. maranonica* and *S. gujanensis*, and all three are often treated as conspecific. Similar in voice and plumage to S races of latter species; thorough analysis of species limits required. Race *simoni* considered a distinct species by some authors. Two subspecies recognized.

**Subspecies and Distribution.**

*S. a. simoni* Hellmayr, 1907 - C Brazil (E Mato Grosso, Goiás).

*S. a. albilora* Pelzeln, 1856 - E Bolivia (E Santa Cruz), SW Brazil (W Mato Grosso) and N Paraguay (E Alto Paraguay, NE Presidente Hayes, N Concepción).

**Descriptive notes.** 15-16 cm; 13-17 g. Nominat race has loreal area whitish, rest of face pale brownish-grey; crown and upper back dull greyish-brown, blending to rufous-brown rump; uppertail-

coverts dark rufous; wings bright rufous, tips of remiges fuscous brown; tail graduated, 10 rectrices, rather blunt, dark rufous; throat white; underparts bright tawny ochraceous, paler belly whitish in centre; iris cinnamon-brown; bill black to dark grey, lower mandible grey; tarsus and toes grey to dull brownish. Sexes alike. Juvenile is duller and more ochraceous below. Race *simoni* differs in having back uniform cinnamon-rufous, mostly white underparts, neck and sides only washed with buff, crown also browner, underwing-coverts paler ochraceous buff. **VOICE.** Song a sharp “keeew, kit-kweet”, usually repeated at intervals of 3–5 seconds.

**Habitat.** Undergrowth of gallery forest and riparian woodland and shrubs; to 1000 m.

**Food and Feeding.** Arthropods; recorded items are spiders, Orthoptera, Coleoptera, ants, Diptera. Usually forages in pairs, often among vines and tangles. Gleans food items from ground, and from foliage and small branches within 1–2 m of ground; rarely ascends above 3 m.

**Breeding.** Nest a large mass of sticks, placed in bush or small tree. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common within its limited range; very numerous in suitable habitat in the Pantanal region.

**Bibliography.** Anon. (2003d), Cory & Hellmayr (1925), Ferreira de Vasconcelos & Trent (2002), Hayes (1995), Hayes *et al.* (1990), Hellmayr (1907d), Naumburg (1930), Parker, Gentry *et al.* (1993), Pinto & Camargo (1952), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Schubart *et al.* (1965), Stotz *et al.* (1996), Tubelis & Tomás (1999), Wetmore (1926).

## 96. Ochre-cheeked Spinetail

### *Synallaxis scutata*

**French:** Synallaxe à bavette **German:** Weißbrauen-Dickichtschlüpfer **Spanish:** Pijui Canela  
**Other common names:** Cinnamon-backed Spinetail

**Taxonomy.** *Synallaxis scutata* P. L. Slater, 1859, Bahia, Brazil.

Often placed with *S. candei* and *S. kollari* in a separate genus *Poecilurus*, but no diagnosable differences from current genus. Considered by some to form a superspecies with those two, but differs substantially from both in colour pattern and tail structure; plumage pattern suggests that it is more likely related to *S. albilora*. Whether darker race *whitii* can be distinguished from extremes of adjacent populations of nominate race, which varies clinally from NE to SW, or whether it is diagnosably distinct, merits investigation. Proposed race *neglecta*, from Ceará (Brazil), supposedly paler rufous above and whiter below, and proposed race *teretiala*, from Serra dos Carajás, in S Pará (Brazil), described from three specimens as smaller and whiter below than nominate, but neither is considered distinguishable. Two subspecies recognized.

**Subspecies and Distribution.**

*S. s. scutata* P. L. Slater, 1859 - E & C Brazil (S Pará and Maranhão E to Ceará and Bahia, S to N Mato Grosso, S Minas Gerais and N São Paulo).

*S. s. whitii* P. L. Slater, 1881 - S Brazil (S Mato Grosso), SE Bolivia (Santa Cruz, Chuquisaca, Tarija) and NW Argentina (Jujuy and Salta, possibly also W Formosa, S to Catamarca).

**Descriptive notes.** 13–14 cm; 12–19 g. Nominant race has broad, conspicuous whitish supercilia almost meeting across forehead, where more buffy, blackish loreal region mixed with whitish, weakly defined dull dark brownish postocular streak, ochraceous buff auriculars and rear malar area; narrow forehead spot blackish, blending to dull greyish-brown crown to upper back; rest of back dark rufous, becoming increasingly greyish-brown (reddish area contracting) from NE to SW; wings dark rufous, except for dark brownish lesser coverts and primary tips; uppertail-coverts and graduated tail rufous, 10 rectrices slightly

pointed, with short “spines”; throat white, black crescent-shaped patch on lower throat; rather dull pinkish-brown to pale ochraceous buff below, blending to paler belly with white in centre, underparts becoming increasingly ochraceous from NE to SW; iris dark chestnut to reddish-brown or brown; upper mandible black to dark grey, lower mandible grey to blue-grey, sometimes with dark tip; tarsus and toes greenish-grey to yellowish-olive. Sexes alike. Juvenile has faint darker scalloping on breast. Race *whitii* differs from nominate in having back to uppertail-coverts uniform brown without any rufous suffusion, wings and tail darker rufous, face and underparts slightly deeper ochraceous. **VOICE.** Song a shrill “tweet, to-wéet”, often repeated for long periods.

**Habitat.** Undergrowth and edge of deciduous forest, locally also in semi-deciduous forest; to 1700 m.

**Food and Feeding.** Arthropods; recorded dietary items include Orthoptera and Hymenoptera. Usually forages in pairs, occasionally in mixed-species flocks. Gleans food items mainly from ground.

**Breeding.** Presumably breeds primarily during austral spring-summer or during wet season; eggs in Apr in E Brazil and nestlings in Nov in NW Argentina. Probably maintains territory throughout year. Nest a large mass c. 45–65 × 35–60 × 20–30 cm, of twigs up to 20 cm long, roots and dead leaves, horizontal entrance tube 20–25 cm long leading to interior chamber c. 10 cm in diameter, placed on ground, often next to tree trunk or fallen log, camouflaged to look like pile of debris; a smaller nest also reported c. 20 cm above water in aquatic vegetation. Clutch 2–3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common throughout range. Occurs in Pedra Talhada State Park, in Brazil, and Calilegua National Park, in Argentina.

**Bibliography.** Babarskas *et al.* (1995), Canevari *et al.* (1991), Cavalcanti & Marini (1993), Chebez *et al.* (1999), Cory & Hellmayr (1925), Davis (1993), Di Giacomo & López (1998), Fjeldså & Maijer (1996), Guerrero & Arambiza (2001), Kirwan *et al.* (2001), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), do Nascimento *et al.* (2000), Naumburg (1930), Oren (1985), Parker, Gentry *et al.* (1993), Parrini *et al.* (1999), de la Peña (1988), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Salvador (1988, 1990), Schulenberg & Awbrey (1997a), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Teixeira & Luigi (1993), Todd & Carriker (1922b), Tubelis & Tomás (1999), Vaurie & Schwartz (1972), Whitney & Pacheco (1994), Willis (1992b), Willis & Oniki (1990, 1991).

## 97. White-whiskered Spinetail

### *Synallaxis candei*

**French:** Synallaxe à moustaches

**German:** Weißbart-Dickichtschlüpfer

**Spanish:** Pijui Barbiblanco

**Other common names:** Cande's Spinetail

**Taxonomy.** *Synallaxis* [sic] *Cande* d'Orbigny and Lafresnaye, 1838, Cartagena, Colombia.

Often placed with *S. scutata* and *S. kollari* in a separate genus *Poecilurus*, but no diagnosable differences from current genus. Forms a superspecies with second of those species, possibly also including the first, but that differs substantially in colour pattern and tail structure. Distributional boundaries of races require confirmation. Three subspecies recognized.

**Subspecies and Distribution.**

*S. c. venezuelensis* Cory, 1913 - extreme N Colombia (Guajira Peninsula, S to César) and NW Venezuela (Zulia E to E Falcón and Lara).

*S. c. candei* d'Orbigny & Lafresnaye, 1838 - N Colombia (N Sucre E to W Magdalena).

*S. c. atrigularis* (Todd, 1917) - N Colombia (middle Magdalena Valley of S Bolívar).

**Descriptive notes.** 15–17 cm; 14–16 g. Distinctive, boldly patterned spinetail. Nominant race has blackish face, broad rufous supercilium from just above eye back to nape; crown dark grey, many feathers blackish-centred, giving mottled look; hindneck to uppertail-coverts bright rufous; wings bright rufous, remiges with dark fuscous tips; tail long, 10 rectrices, shafts slightly stiffened, inner pairs almost square-tipped, feathers bright rufous, distal third dark fuscous; throat black, sharply outlined by broad white malar area and chin; breast and sides bright rufous, flanks slightly paler, belly white, undertail-

coverts dull pale rufous; iris dark brown; upper mandible black, lower mandible black or blackish with ill-defined yellowish at lower centre; tarsus and toes slate-grey to blue-grey. Sexes alike. Juvenile undescribed. Race *venezuelensis* has white throat, black restricted to band on lower throat, plumage generally paler, tail more sharply bicoloured; *atrigularis* lacks supercilium, has malar area and chin flecked greyish-white, back brown, base of tail darker, more dusky chestnut, breast duller, flanks more olivaceous. **VOICE.** Song a nasal “a-dit-dit-du”, often repeated, rather similar to voice of *S. unirufa*. Call a nasal “paa-pip”, extended to long nasal scold when disturbed; alarm a nasal “naaaa”.

**Habitat.** Tropical deciduous forest, arid lowland scrub, usually with cacti as prominent component of arborescent vegetation and ground cover; locally on saltflats with scattered bushes, overgrown pastures, and edges of mangroves. Sea-level to 1100 m.

**Food and Feeding.** Arthropods. Usually forages in pairs. Gleans items mainly from ground beneath shrubs, but also from twigs and branches within 2 m of ground.

**Breeding.** Breeds evidently during wet season, Oct-Jan; eggs and nestlings in Dec in Venezuela. Presumably monogamous. Nest a bulky mass c. 70 cm long, 30–50 cm wide, 30 cm deep, of thorny twigs and branches, slightly curved tunnel leading to inner chamber, latter 10–13 cm in diameter with walls made of thorny twigs, bottom usually lined with green pubescent leaves of *Croton flavens* (or, if those not available, non-pubescent leaves of *Cercidium praecox*), all parts of nest covered with thatching of sticks and bark, on outside forming platform, entrance hole on upper end of structure and often surrounded by pile of thorny twigs elevated above platform, sometimes pieces of snake or lizard skin added to lining or thatch; usually placed 1.3–2.5 m above ground in thorny bush. Clutch 3–4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Caribbean Colombia and Venezuela EBA. Fairly common to common throughout most of range. No data on densities, but in Venezuela, and presumably elsewhere, populations may be quite large in favourable areas.

**Bibliography.** Bosque & Lentino (1987), Collins *et al.* (1991), Cory & Hellmayr (1925), Hilty (2003a), Hilty & Brown (1986), Marini (2001), Remsen (2003a), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vaurie & Schwartz (1972), Whitney & Pacheco (1994).

## 98. Hoary-throated Spinetail

### *Synallaxis kollari*

**French:** Synallaxe du Roraima

**German:** Grauwangen-Dickichtschlüpfer

**Spanish:** Pijui de Roraima

**Other common names:** Kollar's Spinetail

**Taxonomy.** *Synallaxis Kollari* Pelzelin, 1856, Forte do São Joaquim, Rio Branco, Roraima, Brazil. Often placed with *S. scutata* and *S. candei* in a separate genus *Poecilurus*, but no diagnosable differences from current genus. Forms a superspecies with second of those species, possibly also including the first, but that differs substantially in colour pattern and tail structure. Monotypic.

**Distribution.** N Brazil, in R Branco region of N Roraima; sight record from adjacent Guyana.

**Descriptive notes.** 15–16 cm. Has grey-brown crown and lores, wide cinnamon-rufous supercilium from just above eye to nape, slightly darker auriculars diffusely tinged greyish at lower edge, indistinct whitish-buff eyering wider at rear; upperparts, including wings, bright rufous, remiges with dark fuscous tips; tail with 10 rectrices, bright rufous; malar area, chin and upper throat white with black specks, lower throat black; breast cinnamon-rufous like neck side, becoming paler ochraceous on flanks, almost whitish in centre of belly; iris dark reddish-brown; upper mandible blackish-grey, lower mandible blue-grey

with blackish tip; tarsus and toes blue-grey. Differs from *S. candei* mainly in head and tail patterns. Sexes alike. Juvenile undescribed. **VOICE.** Song is of 2 notes, the second higher than first, repeated at 1-second intervals.

**Habitat.** Seasonally flooded gallery forest with dense, vine-rich undergrowth in savannas; 100 m.  
**Food and Feeding.** Little known. Food arthropods. Probably forages usually in pairs. Gleans items from near ground in dense undergrowth.  
**Breeding.** Presumably monogamous. An incomplete nest found in Jul was a cup of twigs, placed 1·5 m above ground in dense bush. No further information.  
**Movements.** Resident.  
**Status and Conservation.** **ENDANGERED.** Restricted-range species; present in Rio Branco Gallery Forest EBA. Known from only about eight localities within a relatively small region, none with any official protection. Total population estimated at fewer than 1000 individuals in 1990s,

and probably declining. Although it inhabits what is, fortunately, a remote area, some agricultural development, especially rice cultivation, has occurred along the rivers in N Roraima; fires may also be a major threat. Habitat preference presumably much more restricted than simply seasonally flooded forest, which is widespread in Amazonia. Surveys needed in order to determine the species' current distribution and population.

## 99. Stripe-breasted Spinetail

### *Synallaxis cinnamomea*

**French:** *Synallaxe guioiti*

**German:** Streifenbrust-Dickichtschlüpfer

**Spanish:** Pijui Pechiestriado

**Other common names:** Cinnamomeous Spinetail

**Taxonomy.** *Synallaxis* [sic] *cinnamomeus* Lafresnaye, 1843, Colombia = "Bogotá".

Although its unusual plumage pattern suggests no close relatives, voice is similar to that of many congeners. Seven subspecies recognized.

#### **Subspecies and Distribution.**

*S. c. cinnamomea* Lafresnaye, 1843 - extreme NW Venezuela (Perijá Mts) and E Andes of Colombia (Magdalena, Santander S to Cundinamarca).

*S. c. aveledoi* Phelps, Sr. & Phelps, Jr., 1946 - W Venezuela (Falcón, W & S Lara to N Táchira) and Andes of N Colombia (Norte de Santander).

*S. c. bolivari* Hartert, 1917 - coastal range of NC Venezuela (Yaracuy E to Miranda and N Guárico).

*S. c. striatipectus* Chapman, 1899 - NE Venezuela (W Sucre, Anzoátegui).

*S. c. pariae* Phelps, Sr. & Phelps, Jr., 1949 - Paria Peninsula (Cerro Humo, Cerro Azul), in NE Venezuela.

*S. c. carri* Chapman, 1895 - Trinidad.

*S. c. terrestris* Jardine, 1847 - Tobago.

**Descriptive notes.** 14-15 cm; 15-23 g. Relatively short-tailed *Synallaxis* with unusual pattern, conspicuously streaked below. N nominate race has dark dull rufous face and vague supercilium, rich brown crown and upperparts; wings rufous-chestnut, remiges with blackish tips; tail graduated, either 8 or 10 rectrices, degree of individual variation differing geographically, sharply pointed, distal 1-2 mm nearly lacking barbs and giving "spiny" appearance, shafts somewhat stiffened, rich brown; throat black with white streaks; underparts rufous with fulvous streaks, belly paler with streaks duller; iris reddish to creamy

brown to dark (source of variation uncertain); upper mandible dark horn to black, lower mandible grey-horn or pinkish blending to dark horn tip; tarsus and toes black to greyish to pale grey-brown. Sexes alike. Juvenile is browner, throat pattern much less distinct, not so black and spots weakly defined, streaks below less distinct. Race *aveledoi* is paler and more yellowish-brown above, buff with dusky streaks below; *bolivari* is more olivaceous above, has whitish chin and throat, throat with wavy black streaks, breast and sides light buffy cinnamon with conspicuous blackish streaks, belly buffy whitish with less conspicuous streaks, flanks and undertail-coverts brownish with some faint streaks; *striatipectus* has darker upperparts, chestnut wings and tail, conspicuous buff supercilium, ochraceous face and neck with blackish edging, ochraceous and heavily streaked blackish below; *pariae* resembles previous, but supercilium less distinct, streaks below duller and more olivaceous (not blackish), belly with fewer streaks; *carri* is dark brown above, no supercilium, throat blacker with narrower white streaking, underparts dull olive-brown with only faint streaking; *terrestris* is palest, generally more olivaceous brown, unstreaked below except for some blurred streaks on breast. **VOICE.** Little geographical variation. Song a nasal, sharp "chik-kwek" or "chúrt-wert", first note higher, second inflected, often repeated rapidly for extended periods; also gives soft, whining "peeuur" or querulous "chew".

**Habitat.** Tropical deciduous forest, gallery forest, arid montane scrub, second-growth scrub; undergrowth and treefalls at edge of or in tropical lowland forest and lower montane forest, also second-growth woodland and overgrown coffee plantations; locally in deciduous forest; forest undergrowth in Trinidad and Tobago. To 2000 m; mostly above 700 m in Venezuela.

**Food and Feeding.** Arthropods; flying ants recorded as taken. Usually in pairs, occasionally in small mixed-species flocks. Gleans items from foliage and small branches within 1-2 m of ground; also gleans and flakes leaf litter on ground.

**Breeding.** Breeding records scattered throughout year in Trinidad; recorded Mar-Aug in Tobago. Presumably monogamous. Nest a mass of thick twigs and dead leaves c. 40 cm tall and 25 cm in diameter, entrance on top, tunnel 15 cm long bending near entrance, placed on sloping ground or up to 3 m above ground in bush. Clutch 3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout range. In Venezuela, very common in mountains of Paria Peninsula, less common and more local in Andes. Occurs in Asa Wright Nature Centre, in Trinidad, and in Henri Pittier, Macarao and Cueva del Guácharo National Parks, in Venezuela. Thrives in forested areas opened by cutting.

**Bibliography.** Anon. (2003k), Belcher & Smoother (1936), Bond *et al.* (1989), Cory & Hellmayr (1925), Dunning (1993), French (1991), Herklots (1961), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee (1946a), Phelps & Phelps (1946, 1963), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stotz *et al.* (1996), Wetmore (1926).

## 100. Russet-bellied Spinetail

### *Synallaxis zimneri*

**French:** *Synallaxe de Zimmer* **German:** Rostbauch-Dickichtschlüpfer **Spanish:** Pijui de Ancash

**Taxonomy.** *Synallaxis zimneri* Koepcke, 1957, near Colcabamba, Casma, Ancash, 2800 m, western Andes of central Peru.

Distinctive, with no obvious close relatives. Some authors have suggested that it merits placement in a separate genus; song and nest, however, are similar to those of many congeners. Monotypic.

**Distribution.** W slope of W Peruvian Andes in W La Libertad and Ancash (Cordillera Negra).

**Descriptive notes.** 13 cm; 12-14 g. One of the most atypical species in the genus in terms of plumage and tail structure. Has blackish loreal area, slightly paler auriculars, broken whitish eyering, vague grey-brown supercilium; crown grey blending to dull dark brownish back, contrasting bright rufous uppertail-coverts; wing-coverts dark rufous, remiges dull brownish; tail graduated, 10

rectrices, blunt, central pair dark fuscous, rest mainly rufous; chin whitish, blending to grey-brown throat and upper breast, faintly streaked; rest of underparts rufous, slightly paler in centre of belly, darker on undertail-coverts; iris dark red-brown; bill black, sometimes grey base of lower mandible; tarsus and toes dark grey. Sexes alike. Juvenile is like adult, but bill shorter and paler. **VOICE.** Song a nasal "quick-quick" or "cue-quec", c. 1 second long, repeated at intervals of 1-2 seconds; chattering trill during disputes.

**Habitat.** Arid montane scrub 1-3 m tall, usually thorny, with occasional isolated short trees, often at edge of dry forest; plants species include *Acca*, *Berberis*, *Cestrum*, *Cordia*, *Croton*, *Dasyphyllum*, *Duranta*, *Heperomeles*, *Randia*, *Sebastiania*, *Solanum*. At 2100-2800 m, mostly above 2500 m; occasionally slightly lower or higher.

**Food and Feeding.** Contents of 8 stomachs consisted of c. 70% arthropods, predominantly winged insects and spiders, and 30% seeds and plant material by volume. Usually forages in pairs, rarely in mixed-species flocks, from understorey to ground. Gleans arthropods from foliage, moss and small branches; also gleans and scratches leaf litter on ground.

**Breeding.** Nestlings in May. Monogamous. Nest a globular mass c. 25-30 cm in diameter, of interwoven thorny twigs, upward-slanting lateral entrance tube c. 20 cm long, also a bulge 18 cm in diameter on upper side of main mass (almost like a third section, but not hollow), inner chamber c. 20 cm in diameter, shallow nest cup 4 cm across, lined mostly with leaf rachides; placed 3-5-4-2 m up in tall shrub (*Sebastiania obtusifolia*) or small tree (*Myrcianthes quinqueloba*) in dense forest, away from usual feeding areas. Clutch at least 2 eggs; female, having lost mate, fed chicks 28 times in 1 hour 33 minutes, each visit 2-5 seconds long, fledglings left nest very soon after.

**Movements.** Resident.

**Status and Conservation.** 1 **DANGERED.** Restricted-range species: present in Peruvian High Andes EBA. Uncommon to locally abundant within very small range. Total population estimated at between 1000 and 3000 individuals in 1990s; believed to be declining as a result of habitat destruction. Does not occur in any protected areas. Habitat in many areas being seriously degraded by livestock grazing, leading to removal of undergrowth and subsequent erosion; scrub also being cleared for agricultural expansion. Surveys required in order to determine this species' precise current distribution and to assess population more accurately. Establishment of one or more protected areas would be of great benefit in ensuring its future survival.

**Bibliography.** Begazo *et al.* (2001), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldsa & Krabbe (1990), Franke & Salinas (2001), Hunnybun (1999), Koepcke (1957), Mayr (1971), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

## 101. Necklaced Spinetail

### *Synallaxis stictothorax*

**French:** *Synallaxe à collier* **German:** Fleckenbrust-Dickichtschlüpfer **Spanish:** Pijui Collarejo

**Other common names:** Spotted-breasted Spinetail; Chinchipe Spinetail (*chinchipensis*)

**Taxonomy.** *Synallaxis stictothorax* P. L. Selater, 1859, Guayaquil, Ecuador.

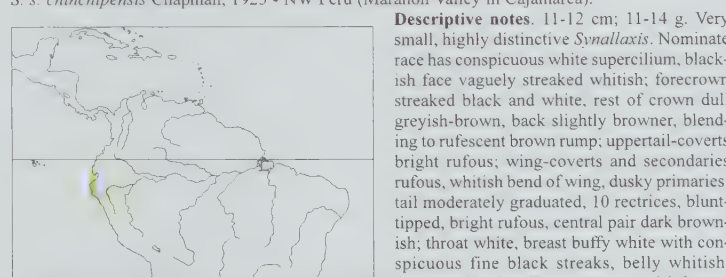

In the past, was sometimes placed in a monotypic genus *Chinchipe* or in *Siptornopsis*. More similar to latter or to *Cranioleuca* in foraging behavior, voice and nest structure; on the other hand, one genetic study based on protein electrophoresis found this species to cluster with present genus rather than with *Cranioleuca*. Further research needed. Race *chinchipensis* treated as a separate species by some authors, but published evidence for this is weak. Three subspecies recognized.

#### **Subspecies and Distribution.**

*S. s. stictothorax* P. L. Selater, 1859 - SW Ecuador (C Manabí S to W Guayas and Puna I).

*S. s. maculata* Lawrence, 1874 - extreme SW Ecuador (S Loja) and NW Peru (Tumbes, Piura, Lambayeque, La Libertad).

*S. s. chinchipensis* Chapman, 1925 - NW Peru (Marañón Valley in Cajamarca).

**Descriptive notes.** 11-12 cm; 11-14 g. Very small, highly distinctive *Synallaxis*. N nominate race has conspicuous white supercilium, blackish face vaguely streaked whitish; forecrown streaked black and white, rest of crown dull greyish-brown, back slightly browner, blending to rufescent brown rump; uppertail-coverts bright rufous; wing-coverts and secondaries rufous, whitish bend of wing, dusky primaries; tail moderately graduated, 10 rectrices, blunt-tipped, bright rufous, central pair dark brownish; throat white, breast buffy white with conspicuous fine black streaks, belly whitish, flanks and undertail-coverts tawny; iris brown

to reddish-brown or brownish-red; bill black, sometimes much of lower mandible grey; tarsus and toes blue-grey to dark grey. Sexes alike. Juvenile undescribed. Race *maculata* has slightly more rufescent back, more extensive rufous in wing (contrast between dark brownish primary coverts and tawny margins of outer primaries), more extensive rufous in tail, only central pair of rectrices with any dusky colour (on distal portion of inner web); *chinchipensis* has much duller, buffy supercilium, greyer flanks, underparts spotted rather than streaked. **VOICE.** Song distinctive, a burst of rapid sputtering notes that descend and fade towards end; call a repeated "chit" or "tset".

**Habitat.** Arid lowland scrub, also deciduous woodland edge; below 400 m.

**Food and Feeding.** Arthropods. Usually forages in pairs. Gleans items from moss, dead leaves and small branches, usually within 1-2 m of ground; unlike its congeners, adopts acrobatic feeding postures.

**Breeding.** Nest a rounded, rambling stick structure with side entrance, similar to that of some *Phacelodomus* thornbirds. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Marañón Valley EBA. Fairly common within rather small range. Occurs in Machalilla National Park, in Ecuador, and Tumbes National Reserve, in Peru. Tolerates moderate habitat degradation.

**Bibliography.** Begazo *et al.* (2001), Best & Clarke (1991), Braun & Parker (1985), Cook (1996), Cory & Hellmayr (1925), Koepcke (1963), Marchant (1960), Parker & Carr (1992), Parker *et al.* (1982), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Walker (2003).

Genus *SIPTORNOPSIS* Cory, 1919

## 102. Great Spinetail

*Siptornopsis hypochondriaca*

**French:** Synallaxe à poitrine rayée

**Spanish:** Curutié Grande

**German:** Weißbrust-Dickichtschlüpfer

**Other common names:** Salvin's Spinetail

**Taxonomy.** *Siptornis hypochondriacus* Salvin, 1895, Malca and Cajabamba, Cajamarca, Peru. Close relationship to *Synallaxis stictothorax* suggested by plumage pattern and biogeography. Monotypic.

**Distribution.** NC Peru in upper Marañón Valley (S Cajamarca, extreme SW Amazonas, La Libertad, N Ancash).

**Descriptive notes.** 17-19 cm; 23-26 g. Large-billed, long-tailed spinetail. Broad white supercilium extends to side of forehead; lores and auriculars dark greyish, becoming brownish and streaked towards neck; crown dull brown with faint buffy streaks in forehead centre, blending to slightly paler back; rump and uppertail-coverts light greyish-brown; rufous lesser and median coverts, brown greater coverts, and blackish primary coverts, dull tawny-olive margins of dusky remiges; tail graduated, 12 rectrices with slightly stiffened shafts, rather blunt tips, dusky brown; throat white, malar area tinged creamy; breast white with conspicuous blackish streaks, streaks strongest at sides, belly whitish with some faint dusky streaking at margins, flanks brownish with indistinct dark-edged whitish streaks fading posteriorly; undertail-coverts whitish with hint of blurred dark streaks; iris chestnut to reddish-brown; lower mandible black to dark brown, upper mandible blue-grey usually with dusky tip; tarsus and toes blue-grey. Sexes alike. Juvenile is less extensively streaked below, perhaps has pinkish lower mandible. Voice. Song a loud, rapid burst of sputtering notes, decreasing in speed towards end, similar to that of *Synallaxis stictothorax*, often given as duet, with some whining notes added by female. Call a liquid "chee-cheep", often given immediately before song.

**Habitat.** Xerophytic thorny montane scrub with cacti, at lower elevations mixed with Bombax trees; 1650-3000 m.

**Food and Feeding.** Recorded diet items are Coleoptera. Usually in pairs. Gleans arthropods from dense foliage and small branches, usually within 1-2 m of ground.

**Breeding.** Builds large, enclosed stick nest, reminiscent of that of *Phacellodomus* thornbirds. No further information.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Marañón Valley EBA. Uncommon to rare. Known from few localities. Owing to its small and linear range, this species' total population is rather small, estimated at fewer than 10,000 individuals in 1990s. Declining as a result of habitat destruction. Its apparent dependence on dense natural vegetation makes it vulnerable to habitat degradation caused by grazing and firewood-cutting. Remaining areas of scrub also threatened, at least in some areas, by agricultural expansion and the planting of oil palms (*Elaeis guineensis*).

**Bibliography.** Begazo *et al.* (2001), Bond (1945), Braun & Parker (1985), Cory & Hellmayr (1925), Dinerstein *et al.* (1995), Fjeldså & Krabbe (1990), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Walker (2003).

Genus *GYALOPHYLAX* J. L. Peters, 1950

## 103. Red-shouldered Spinetail

*Gyalophylax hellmayri*

**French:** Synallaxe de Hellmayr

**Spanish:** Pijui de Hellmayr

**German:** Rotschulter-Dickichtschlüpfer

**Other common names:** Reiser's Spinetail

**Taxonomy.** *Synallaxis hellmayri* Reiser, 1905, Fazenda Serra, Rio Grande, Bahia, Brazil. Previously named *Synallaxis griseiventris*, but that name invalid. Included in *Synallaxis* by many authors, and thought by others to be possibly more closely related to *Synallaxis hypospodia* than either is to others of that genus, the two having similarities in voice, rectrix shape and plumage; differs morphologically from that genus, however, in having 12 rectrices, thicker tarsus and toes, different bill shape. Was at one time placed in *Asthenes*, and described by some authors as resembling members of that genus. Considered better retained in monotypic genus until relationships resolved. Monotypic.

**Distribution.** E Brazil (NE Piauí, W Pernambuco, N Bahia, extreme N Minas Gerais).

**Descriptive notes.** 18-19 cm; 25-26 g. Superficially like other spinetails, but subtle differences include wedge-shaped bill. Male has crown, back and upperparts uniform fuscous brown; dull chestnut wing-coverts, fuscous brownish-grey remiges; tail strongly graduated, 12 rectrices, slightly stiffened shafts, blunt tips, blackish; chin and throat black; underparts fuscous brownish-grey, paler belly buffier in centre; iris orange to rufescent; bill black to blackish-brown; tarsus and toes grey. Sexes probably alike; unconfirmed report that one member of pair always darker overall, with blacker throat, brighter red shoulders, darker

orange iris. Juvenile has greyish wing-coverts. Voice. Song a loud, fast, accelerating series that fades towards end, 3-5-4-5 seconds long, usually introduced with 1-4 quiet, widely spaced dry notes. Call given reciprocally by members of foraging pair "tre-tre" or "tchi-kr", often repeated; alarm a quiet oscillating scold c. 1 second in duration.

**Habitat.** Arid, scrubby deciduous woodland (e.g. *caatinga* "arbustiva densa"), usually with dense thickets of terrestrial bromeliads (especially *Bromelia laciniosa*); 200-400 m.

**Food and Feeding.** Mainly arthropods; recorded dietary items are spiders, Coleoptera, Orthoptera, also seeds. Forages usually in pairs, generally on ground or within 1-2 m of it. Gleans arthropods from leaf litter, foliage (including *B. laciniosa* leaves), debris trapped in foliage, and small branches. Searching of dead leaves on ground is the predominant foraging behaviour, at least during dry season; keeps head close to ground, as if listening for movements of hidden arthropods, and gleans, flakes and tosses dead leaves; sometimes uses feet simultaneously to disturb leaves.

**Breeding.** Season probably Oct-Apr; eggs in Oct and fledglings in Jan. Presumably monogamous. One nest described, a large mass 50-100 cm long, 25 cm high, built from spines of the cactus *Pilocereus gounellei*, lateral entrance tube 25 cm long, entrance hole opening diagonally upwards. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in North-east Brazilian Caatinga EBA. Locally common and fairly widespread within range. Only recently discovered in Minas Gerais. Appears to be less restricted to woodland containing the large terrestrial bromeliad *B. laciniosa* than was previously believed. Recently found to be present in areas disturbed by cattle grazing and goats. Intensive grazing, however, remains a threat, as also do burning of dry woodland, exploitation of dry *caatinga* for charcoal, and conversion of habitat to agricultural uses.

**Bibliography.** Collar *et al.* (1994), Cory & Hellmayr (1925), Ihering (1914), Kirwan *et al.* (2001), do Nascimento *et al.* (2000), Parrini *et al.* (1999), Peters (1950), Pinto (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Teixeira (1992), Willis (1992b).

Genus *HELLMAYREA* Stolzmann, 1926

## 104. White-browed Spinetail

*Hellmayrea gularis*

**French:** Synallaxe à sourcils blancs

**Spanish:** Pijui Paramero

**German:** Kurzschwanz-Dickichtschlüpfer

**Other common names:** Lafresnaye's (White-browed) Spinetail

**Taxonomy.** *Synnalaxis* [sic] *gularis* Lafresnaye, 1843, Colombia = "Bogotá".

Formerly placed in genus *Synallaxis*, but differs in voice and foraging behaviour; almost certainly more closely related to *Cranioloeua* or *Schizoeaca*. Validity of race *cinereiventris* merits investigation, as similar-looking birds have been reported near localities of nominate in Cundinamarca (Colombia). Proposed races *rufipectus* (C Andes of Colombia), described as more rufescent above and below, and *pichincae* (Andes of Ecuador), said to differ from it in being paler below and darker above, considered indistinguishable from nominate. Four subspecies recognized.

**Subspecies and Distribution.**

*H. g. gularis* (Lafresnaye, 1843) - Andes of W Venezuela (S Táchira), Colombia (all three ranges), Ecuador and N Peru (Cajamarca).

*H. g. brunneidorsalis* Phelps, Sr. & Phelps, Jr., 1953 - NE Colombia and NW Venezuela (Perijá Mts).

*H. g. cinereiventris* (Chapman, 1912) - Andes of W Venezuela (Trujillo S to N Táchira).

*H. g. rufiventris* (Berlepsch & Stolzmann, 1896) - Andes of N & C Peru (Amazonas S to Junín).

**Descriptive notes.** 11-13 cm; 11-15 g. Distinctively short-tailed spinetail. Nominate race has narrow whitish supercilia nearly meeting on forehead; loreal region, face and malar area dark rufescent brown, vague darker streaks on auriculars; centre of forehead, crown and nape rufescent brown with faintly paler shaft streaks, upperparts, including wings, also rufescent brown; tail graduated, 10 rectrices slightly stiffened basally, sharply pointed, nearly lacking barbs at tips, slightly disintegrated, rufescent brown; throat white, narrow lower border of blackish-based feathers giving weak "necklaced" look; under-

parts uniform cinnamon-brown to buffy brown, sometimes greyer; iris dark brown to brown; upper mandible black to dark grey, lower mandible pinkish-horn to grey with dark tip; tarsus and toes olive, olive-brown or olive-yellowish. Sexes alike. Juvenile has dark tips on breast and belly feathers. Race *brunneidorsalis* differs from nominate in having browner, less rufescent upperparts, paler and greyer underparts, brown restricted to flanks; *cinereiventris* is darker, richer brown above, underparts brownish-grey; *rufiventris* is darker overall, more rufescent above, more dark chestnut below. Voice. Song a series of high-pitched notes ending in trill, "chit-chit-

per mandible black, lower mandible dull horn to silvery horn, cutting edges paler; tarsus and toes dull greenish-olive or greyish. Differs from very similar *C. vulpecula* mainly in darker breast. Sexes alike; some suggestion that male may have more rufescent back (contrasting with crown) than female. Juvenile has more greyish upperparts, underparts variably washed ochraceous with faint mottling. Race *dissita* has brighter, more rufescent underparts, reduced brown on forehead, shorter bill; *apurensis* is darkest, darker crown, wings and tail, also less contrast between forehead and crown; *foxi* has darker rufous upperparts than nominate; *reiseri* is palest, has more rufescent upperparts, paler and more buffy underparts, no hint of streaks on breast. Voice. Song a rapid series of emphatic notes gradually accelerating but fading, lasting c. 2·5–3 seconds, “ch-ch-ch-ch-ch-ch-chewewewewewewew”, also described as descending series of scolding, complaining notes, “chow-chow-chow-chow-chow-chow-chow”, length variable; frequently duets; race *dissita* song

evidently different, more like that of *C. erythrops*. Call a soft, nasal, rising "choy", "choy-choy" or "kuee-kwee".

**Habitat.** Gallery forest, river-island scrub, riparian thickets; variety of wooded water-edge habitats, including *varzea* forest with dense vine-choked vegetation, shrubby vegetation at edges of lakes and streams; from near sea-level to 400 m. Race *dissita* inhabits forest and edge.

**Food and Feeding.** Arthropods; recorded items are Lepidoptera larvae (including Geometridae) and Coleoptera (including Elateridae). Singly or in pairs, occasionally with mixed-species flocks. Forages by hitching along small branches, mostly 1-7 m above ground. Acrobatically gleans arthropods from bark, bases of leaf stems, and dead leaves, occasionally from green foliage.

**Breeding.** Eggs in Jun-Jul in W Venezuela and Nov in E Brazil. Presumably monogamous. Nest a roughly globular mass c. 20-40 cm in diameter, of grass, roots and sticks, camouflaged to look like flood debris, chamber lined with shreds of bark and lichens, 1-4 m above ground or water and wedged into fork of partly submerged sapling or bush; although some early authors thought that the mass was deposited by rising water, direct observations indicate that it is constructed by the birds themselves. Clutch 2-3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout range. Race *dissita*, often treated as possibly a separate species, is currently considered Near-threatened; also a restricted-range taxon, present in South Central American Pacific Slope EBA. Fairly common on Coiba I, but possibly threatened by introduced predators and vulnerable to natural events such as hurricanes.

**Bibliography.** Anon. (1998a), Cherrie (1916b), Cory & Hellmayr (1925), García *et al.* (1999), Gyldestolpe (1945a, 1945b), Hilty (2003a), Hilty & Brown (1986), Marini (2001), Naumburg (1930), Parker *et al.* (1982), Peters (1950), Pinto (1978), Pinto & Camargo (1952), Piratelli *et al.* (2000), Remsen & Traylor (1989), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rosenberg, G.H. (1997), Zimmer, K.J. & Hilty (1997), Zimmer, K.J., Parker *et al.* (1997).

## 108. Parker's Spinetail *Cranioleuca vulpecula*

**French:** Synallaxe de Parker **German:** Parkers Buschschlüpfer **Spanish:** Curutié de Parker

**Taxonomy.** *Synallaxis vulpecula* P. L. Slater and Salvin, 1866, Rio Ucayali, Peru.

Almost certainly the sister-species to *C. vulpina*; formerly considered conspecific, but they are locally syntopic and widely sympatric, and field experiments strongly suggest reproductive isolation created by differences in songs. Relationships of the two to congeners uncertain; they differ vocally from all others. Monotypic.

**Distribution.** E Ecuador (R Napo), NE Peru (R Amazon, lower R Ucayali), SW Amazonian Brazil (R Amazon E locally to R Negro, also R Juruá, R Purus, upper R Madeira) and extreme NE Bolivia (lower R Beni in Pando).

**Descriptive notes.** 13-14 cm; 17-21 g. Has dull buff supercilium, dark brownish lores and postocular stripe, vaguely flammulated auriculars; forecrown cinnamon-brown, blending to reddish-rufous crown and upperparts, including wings and tail; graduated tail, pointed rectrices with shafts stiffened at base; throat whitish, breast indistinctly streaked whitish and pale dull brownish, blending to slightly darker belly; flanks and undertail-coverts browner; iris brown to chestnut; upper mandible black to dark grey, lower mandible greyish-white to pinkish; tarsus and toes greyish-green to olive. Distinguished from very

similar *C. vulpina* mainly by paler breast. Sexes alike. Juvenile has duller crown. **VOICE.** Song an accelerating and descending series of nasal "tew" notes that ends in chortling trill, variable in length; also as duet. Call described as "chut-chut", sometimes repeated, higher and thinner than comparable calls of *C. vulpina*.

**Habitat.** River-island scrub; early-successional scrub on young to medium-aged river islands, from *Tessaria* scrub to *Cecropia* woodland, locally ranging into taller woodland; in some areas always with *Gynierium sagittatum* present; in others found in mature stands of *Alchornea castaneifolia* (Euphorbiaceae). At 150-300 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, from undergrowth up to subcanopy. Gleans items from stems, bark crevices and holes on small branches, leaf bases and foliage, and from debris deposited in vegetation by flooding; occasionally hangs upside-down.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout range. Linear nature of habitat naturally makes global population rather small.

**Bibliography.** Cohn-Haft (2003a), Cory & Hellmayr (1925), García *et al.* (1999), Gyldestolpe (1945a), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg, G.H. (1990), Wetmore (1957), Zimmer (1997).

## 109. Sulphur-throated Spinetail *Cranioleuca sulphurifera*

**French:** Synallaxe soufré **German:** Flügelspiegel-Riedschlüpfer **Spanish:** Curutié Ocráceo  
**Other common names:** Sulphur-bearded Spinetail

**Taxonomy.** *Synallaxis sulphurifera* Burmeister, 1869, near Buenos Aires, Argentina.

Distinctive species; relationships within genus uncertain. Monotypic.

**Distribution.** E. Argentina (SE Córdoba, S Santa Fe and S Corrientes) to E Rio Negro and S Buenos Aires), extreme S Brazil (Rio Grande do Sul) and Uruguay.

**Descriptive notes.** 15-16 cm; 12-14 g. Distinctive *Cranioleuca* with yellow throat patch. Has buffish-white supercilium, rest of face whitish with greyish streaks; crown and upperparts olive-brown; rufous greater and median wing-coverts contrasting with dark fuscous primary coverts and secondaries, and with rich tawny bases of outer primaries; tail graduated, rectrices stiffened basally, somewhat disintegrated distally (especially elongated central pair) and sharply pointed, giving strongly forked appearance, central feathers brownish, outer more rufous; chin and centre of throat yellow; breast

whitish with fine greyish streaks, belly whitish, flanks and undertail-coverts tawny-buff; iris whitish-red to orange-pink; upper mandible blackish-brown to black, lower mandible pinkish-white to whitish; tarsus and toes greenish-grey to pale olive-green. Sexes alike. Juvenile has darker upperparts, ochraceous underparts, lacks yellow throat feathers, no streaks on breast.

**VOICE.** Song a slightly rising trill c. 2.5-3.5 seconds long, followed by rapid series of harsh notes that fade towards end, "d-d-d-r-r-i-i", dirip, dirip, dirip, drip-drip-dreeuw-dreeuw", sometimes followed by upslurred trill; partners duet.

**Habitat.** Freshwater marshes with tall emergent vegetation, ranging into adjacent scrub; to 300 m.

**Food and Feeding.** Little known. Diet probably arthropods. Occurs mostly singly or in pairs; three birds observed to take small insects from *Baccharis salicifolia* stems in Argentina.

**Breeding.** Season during austral spring-summer; eggs in Oct-Dec and nestlings in Nov. Presumably monogamous. Nest an oval mass c. 15-20 × 10-15 cm, mainly of reed fragments with other plant material incorporated, interior lined with grasses and feathers, attached to or supported from below by stems (e.g. of *Scirpus, Spartina*), 0.4-1.6 m above water in emergent vegetation, occasionally above mud or drier ground. Clutch usually 3 eggs, sometimes 2 or 4.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common; rare in S of range. Occurs in Costanera Sur Ecological Reserve and Ingeniero Otamendi Reserve, in Argentina. Restriction to wetlands makes it susceptible to the usual suite of conservation problems that afflict wetland species.

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuervo (1985), García *et al.* (1999), López *et al.* (1999), Mauricio & Bencke (2000), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1988), Norez & Yzurieta (1979b), Norez *et al.* (1983), Olrog (1963a), de la Peña (1987, 1988, 1997), Pinto (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Tittarelli (2002), Willis (1992b), Wetmore (1926).

## 110. Crested Spinetail *Cranioleuca subcristata*

**French:** Synallaxe huppé **German:** Strichelscheitel-Baumschlüpfer **Spanish:** Curutié Copetón

**Taxonomy.** *Synallaxis subcristata* P. L. Slater, 1874, near Caracas, Venezuela.

Considered by some authors to be closely related to, or even to form a superspecies with, *C. pyrrhophia* because of shared plumage feature; others expand this superspecies to include also *C. henricae*, *C. obsoleta*, *C. pallida*, *C. albicapilla*, *C. antisiensis* and *C. baroni*, but genetic data indicate that at least the last two of those are not part of this lineage. Race *fuscivertex* described from only 2 specimens, poorly known; further research desirable. Two subspecies recognized.

**Subspecies and Distribution.**

*C. s. subcristata* (P. L. Slater, 1874) - N Venezuela (Maracaibo Basin, Sierra de San Luis in Falcón, E slope from Lara S to Barinas, mountains from Yaracuy E to Miranda, Cerro Platillón on Arauca-Guárico border, and mountains of NE Anzoátegui, Sucre and N Monagas) and NE Colombia (E slope of E Andes in Norte de Santander S to S Boyacá, and adjacent lowlands of R Arauca and R Casanare). *C. s. fuscivertex* Phelps, Sr. & Phelps, Jr., 1955 - E slope of Andes in W Venezuela (S Táchira, W Apure).

**Descriptive notes.** 14-15 cm; 14 g. Rather long-billed *Cranioleuca* with very slight crest. Has inconspicuous whitish-brown supercilium, dull brownish face, vaguely flammulated auriculars; crown indistinctly striped dark brown and pale brown, feathers elongated to form slight crest (barely, if at all, visible in field); upperparts brown; wings mainly dark rufous, tips of remiges dark fuscous; tail graduated, rectrices with stiffened shafts, mainly at base, and pointed tips, dark rufous; chin whitish-buff, blending to uniform dull tawny-brownish underparts; iris chestnut to cream (source of variation unknown); upper mandible

brownish-flesh, lower mandible dull yellowish to pinkish; tarsus and toes dull yellowish-flesh to greenish-yellow. Sexes alike. Juvenile is greyer, more mottled below, lacks pointed tips of crown feathers, side of crown tinged rufescent. Race *fuscivertex* has more prominent and blacker stripes on head. **VOICE.** Song 3 high, shrill notes followed by chatter descending trill, "pzeep, pzeep, pzeep, pee-pee-e-e-e", lasts 1.5-2 seconds; call a sharp "tsink"; also low rattle.

**Habitat.** Primarily montane evergreen forest; tropical lowland evergreen forest locally, mainly in Maracaibo Basin (Venezuela). Inhabits forest and woodland, extending locally to tall second growth and plantations, in both humid and semi-humid regions. At 50-1950 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, often in mixed-species flocks, from mid-storey up to subcanopy. Hitches and climbs along small branches; acrobatically gleans items from bark and debris.

**Breeding.** Season Jan-Jun in N Venezuela. Presumably monogamous. Nest a globular mass of mainly grass, entrance hole near bottom, suspended from end of branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in much of range; rather uncommon and local in Andes. Occurs in Henri Pittier, Macarao and Guaramacal National Parks, in Venezuela.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), García *et al.* (1999), Hilty (2003a), Hilty & Brown (1986), Majer & Fjeldså (1997), Phelps & Phelps (1955), Remsen (2003a), Ridgely & Tudor (1994), Rodner *et al.* (2000), Schäfer & Phelps (1954), Stotz *et al.* (1996), Vuilleumier (1980a).

## 111. Stripe-crowned Spinetail *Cranioleuca pyrrhophia*

**French:** Synallaxe à calotte rayée

**German:** Streifenscheitel-Baumschlüpfer

**Spanish:** Curutié Ventri blanco

**Taxonomy.** *Dendrocopos pyrrhophius* Vieillot, 1818, Paraguay.

Genetic data indicate that this is sister-species to *C. henricae*. Closely related also to *C. obsoleta*, which suggested by some as race of present species; varying degrees of similarity between them in SE Brazil, Uruguay and NE Argentina demonstrated in recent study as indicative possibly of past or current hybridization or perhaps independent variation; further study needed. All three considered by some to form a superspecies that also includes *C. subcristata*, *C. pallida*, *C. albicapilla*, *C. antisiensis* and *C. baroni*, but genetic data suggest that at least the last two of those are not part of this lineage. Geographical variation clearly more complex than indicated by current taxonomy, but may be largely clinal, plumage becoming more greyish above and more whitish below towards S; within populations assigned to nominate race, variation in crown streaking evidently great, with streaking reduced in SE Brazil but many birds elsewhere at least as streaked as *striaticeps*, and those from lowland S Bolivia closer in appearance to nearby montane population of that race but having undertail-coverts like nominate. Further study needed. Three subspecies recognized.

**Subspecies and Distribution.**

*C. p. rufipennis* (P. L. Selater & Salvin, 1879) - N Bolivian Andes in La Paz (Tiltilo) and NW Cochabamba.

*C. p. striaticeps* (d'Orbigny & Lafresnaye, 1837) - Andes of C & S Bolivia (C Cochabamba, W Santa Cruz, Chuquisaca, Tarija).

*C. p. pyrrhophia* (Vieillot, 1818) - S Bolivia (lowland Santa Cruz and Tarija), W Paraguay, NE & C Argentina (S to Neuquén, Rio Negro and N Buenos Aires), extreme SE Brazil (S Rio Grande do Sul) and Uruguay.

**Descriptive notes.** 13-16 cm; 10-16 g. Rather small *Cranioleuca* with distinctive crown and tail patterns. Nominative race has broad white supercilium, dark brownish lores and post-ocular area, rest of auriculars whitish mixed with brown; most of crown boldly striped with blackish and buffy brown (streaking reduced in S Brazil and Uruguay), blending to plain greyish-brown hindcrown and back (brownish in lowland S Bolivia); rump and uppertail-coverts brownish; wing-coverts mainly rufous, dark brown primary coverts, dull brownish remiges; tail graduated, rectrices stiffened basally, very pointed at tips, outer webs much narrower than

inner ones, producing forked appearance, central feathers mostly dull dark brown or mostly rufous with dark brown inner webs, next two pairs mostly rufous with varying amounts of dark brown along shafts and at tip, outer feathers rufous; throat whitish, blending to very pale brownish-grey or buffish-grey breast and to darker belly (breast and belly paler in lowland S Bolivia), browner

flanks and undertail-coverts; iris dark red to pale orange to dark brown (source of variation unknown); upper mandible black to grey, lower mandible pinkish-horn to pinkish with dark tip; tarsus and toes olive-green to greenish-grey or yellowish-brown. Sexes alike. Juvenile has uniform crown feathers rounded at tips, darker underparts variably mottled or faintly scaled. Race *striaticeps* has generally more extensive crown streaking, slightly browner back, deep rufous uppertail-coverts and central rectrices, paler and less greyish-tinged breast and belly, rufescent tinge on undertail-coverts; *rufipennis* is like previous, but crown streaks narrower and more sharply defined, back browner, outer webs of secondaries rufous. **VOICE.** Song an accelerating, descending trill without introductory notes, c. 1.5-2.5 seconds long; also longer song, 4-12 seconds, few widely spaced metallic "tick" notes followed by rapid series of high, descending, bubbly, clicking "chack" notes, often as duet; also similar, much softer trill, and various other vocalizations. Call described as soft, metallic "tck" or rapid "tidrit".

**Habitat.** Tropical deciduous forest, gallery forest, arid montane scrub, second-growth scrub; variety of woodland types, from semi-humid deciduous to arid Chaco scrub, and low second growth; *Alnus* and *Podocarpus* woodland in Andes. From near sea-level to 3100 m.

**Food and Feeding.** Arthropods; recorded items are ants (*Pheidole*) and Coleoptera (Hydrophilidae). Forages singly or in pairs, often in mixed-species flocks, from near ground up to canopy. Hitches and climbs along small branches, occasionally hanging acrobatically upside-down and even climbing downwards; gleans items from bark, lichens, mosses and epiphytes.

**Breeding.** Season during austral spring-summer; in Argentina, eggs in Oct-Dec, and nestlings in Oct-Nov in W, Dec in E and Feb in NW; nestlings in Oct in S Brazil. Presumably monogamous. Nest an oval mass c. 13-20 cm in diameter, 15-25 cm in height, mainly of sticks, sometimes thorny ones, with other plant material, hair and feathers incorporated, or (in E populations) largely of softer plant materials (especially *Tillandsia usneoides*), entrance hole (sometimes two, possibly only dormitory nests) on side above or below centre, interior lined with soft plant material and feathers; placed 2-5 m up in crotch of small tree or bush, or possibly occasionally suspended from branch. Clutch 2-3 eggs; nestling period 13-15 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in much of its large range; uncommon in Paraguay. Tolerant of habitat disturbance; often present in areas with only small patches of habitat remaining, including mere thickets and hedgerows in agricultural regions. Race *rufipennis* known from only three localities (one of which is N of range of *C. henricae*); has not been definitely recorded for at least 50 years, and may be endangered.

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Claramunt (2002, 2003), Cory & Hellmayr (1925), Cuervo (1985), Fiora (1933), Fjeldså & Krabbe (1989, 1990), Fjeldså & Majer (1996), Fraga & Narosky (1985), Garcia *et al.* (1999), Guerrero & Arambiza (2001), Hayes (1995), Krabbe *et al.* (1996), Kratter *et al.* (1993), Majer & Fjeldså (1997), Mazar Barnett & Pearman (2001), Mezquida (2001b), Narosky *et al.* (1983), Norez *et al.* (1983), Ochoa (1971), Olrog (1963a), Parker, Gentry *et al.* (1993), de la Peña (1987, 1988, 1997), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Salvador (1988), Schmitt *et al.* (1997), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Wetmore (1926), Zotta (1936).

## 112. Bolivian Spinetail

### *Cranioleuca henricae*

**French:** Synallaxe d'Inquisivi **German:** La Paz-Baumschlüpfer **Spanish:** Curutié Boliviano

**Taxonomy.** *Cranioleuca henricae* Maijer and Fjeldså, 1997, 3 km north of Inquisivi, 2350 m, La Paz, Bolivia.

Genetic data indicate that this is sister-species to *C. pyrrhophia*; the two are considered by some to form a superspecies that also includes *C. subcristata*, *C. obsoleta*, *C. pallida*, *C. albicapilla*, *C. antisiensis* and *C. baroni*, but genetic data suggest that at least the last two of those are not part of this lineage. Monotypic.

**Distribution.** R Cotacajes drainage in La Paz (sight records also from R Consata drainage) and Cochabamba, in C Bolivia.

**Descriptive notes.** 14-15 cm. Has whitish lores, black patch in front of eye, white supercilium, vague dull fuscous postocular band; rest of face greyish-brown with faint buff streaks; forehead blackish with thin rufous streaks, crown rufous, some thin dark streaks extending to anterior crown; back brownish-olive, becoming more tawny on rump and more rufescent on uppertail-coverts; wings mostly rufous-chestnut; tail graduated, rectrices with stiffened shafts at base, distal 1-2 mm devoid of barbs and giving "spiked" appearance, rufous-chestnut; throat whitish or dingy white; underparts pale greyish-olive, darker on

undertail-coverts; iris warm brown; bill pinkish, sooty culmen and tip of lower mandible; tarsus and toes olive-yellow. Sexes alike. Juvenile undescribed. **Voice.** Most frequent song a bouncy, accelerating and descending series of sharp notes, sometimes ending in short trilled "trrrrr", lasts c. 1.5-2 seconds, sometimes to 4 seconds, often repeated at short intervals; also longer, more irregular song, 3.5-14 seconds, going up and down in pitch but tending to descend overall, often as duet. Call a rich churring "t-t-t" or "titttt", repeated.

**Habitat.** Montane deciduous woodland and scrub; inhabits woodland dominated by *Schinus molle*, *Schinopsis haenkeana* and *Ceiba mandonii*; also *Prosopis*, *Aspidosperma*, and columnar cacti (*Cereus*, *Samaipaticereus*); also ranges into adjacent low brush. At 1800-2500 m, possibly to 3300 m.

**Food and Feeding.** Arthropods. Usually seen in pairs; joins mixed-species flocks occasionally to regularly, especially in dry season. Forages from understorey to subcanopy. Hitches along small branches, mainly 1-4 m up; acrobatically gleans food items from bark and foliage.

**Breeding.** No information. Possible juvenile observed in Jan.

**Movements.** Resident.

**Status and Conservation.** **ENDANGERED.** Common within tiny range of c. 3000 km<sup>2</sup>. Population estimated at c. 1000-2500 individuals; declining as a result of habitat destruction. All suitable habitat within the species' known range degraded or threatened to varying degrees by overgrazing and by clearance for agriculture; intensive human use of dry valleys for centuries has undoubtedly dramatically reduced extent of woodland. Stronghold of population near Inquisivi, in La Paz, currently threatened by landslides resulting from erosion caused by changes in local hydrology; these changes due to extensive planting with eucalyptus (*Eucalyptus*). Surveys required in order to determine its precise distribution; conservation initiatives needed include action to prevent continued landslides, and encouragement of traditional methods of land use whereby natural woodland not destroyed.

**Bibliography.** García *et al.* (1999), Herzog, Fjeldså *et al.* (1999), Herzog, Kessler *et al.* (1997), Lowen & Kennedy (1999), Maijer (1999), Maijer & Fjeldså (1997), Ridgely & Tudor (1994), Stattersfield & Capper (2000).

## 113. Olive Spinetail

### *Cranioleuca obsoleta*

**French:** Synallaxe olive **German:** Braunoliv-Baumschlüpfer **Spanish:** Curutié Oliváceo  
**Other common names:** Red-tailed Spinetail

**Taxonomy.** *Leptoxyrura obsoleta* Reichenbach, 1853, Brazil.

Closely related to *C. pyrrhophia*, and suggested by some as being conspecific; varying degrees of similarity between them in SE Brazil, Uruguay and NE Argentina demonstrated in recent study as indicative possibly of past or current hybridization or perhaps independent variation; further study needed. Both considered by some to form a superspecies that also includes *C. subcristata*, *C. henricae*, *C. pallida*, *C. albicapilla*, *C. antisiensis* and *C. baroni*, but genetic data suggest that at least the last two of those are not part of this lineage. Proposed race *siemradskii* (Paraná, in Brazil) regarded as indistinguishable. Monotypic.

**Distribution.** E Paraguay, SE Brazil (S São Paulo S to S Rio Grande do Sul), NE Argentina (Misiones, N Corrientes) and E & S Uruguay.

**Descriptive notes.** 13-15 cm; 12-16 g. Small, short-billed, relatively dull *Cranioleuca* with plain brown crown. Has whitish supercilium, dull brown postocular band, with auriculars and moustachial region vaguely flammulated dull buff and brown, malar area plain dull buff; forehead vaguely flammulated brown and buff, blending to dull brownish-olive crown, slightly richer brown back and rump; dark chestnut-rufous wing-coverts, dull dark brown primary coverts, warm brown remiges; tail graduated, rectrices with stiffened shafts at base, devoid of barbs for distal 1-2 mm, giving "spiny" appearance, chestnut-rufous; throat whitish,

breast buffy brownish, blending to pale olive-buff belly, darker flanks and undertail-coverts; iris

dull red to orange to nearly whitish (source of variation unknown); upper mandible black to dark brownish, lower mandible pinkish, bluish-grey or whitish with dark tip; tarsus and toes greyish-olive to olive-green. Sexes alike. Juvenile has darker upperparts, variable amount of dark sealing on underparts, especially breast. **Voice.** Song a fast, accelerating series of high-pitched "psee" notes that gradually descend and end in trill, described as virtually identical to that of *C. pyrrhophia* where they meet in SE Brazil (Rio Grande do Sul); calls described as "tst" and short, hard trill.

**Habitat.** Humid forest and second growth, including *Araucaria* woodland; from near sea-level to 1000 m.

**Food and Feeding.** Arthropods. Usually in pairs, often with mixed-species flocks. Forages primarily in mid-storey, occasionally up to canopy. Hitches along branches and small trunks; often uses tail for support, especially when ascending vertical trunks and branches. Acrobatically gleans items from moss, epiphytes and bark.

**Breeding.** Little known. Season presumed to be during austral spring-summer; eggs in Oct. Presumably monogamous. Nest a slanted, oblong mass, possibly of moss, entrance hole near top of lower side. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally fairly common to common; rare in Paraguay. In Brazil, uncommon in Iguaçu National Park and common in Aparados da Serra National Park. Occurs in San Rafael National Park, in Paraguay. Has relatively small range, within which extensive deforestation has dramatically reduced total area of its habitat.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Anon. (2003d), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Claramunt (2002), Cordeiro (2001), Cory & Hellmayr (1925), Fjeldså & Maijer (1996), Fraga & Narosky (1985), García *et al.* (1999), Hayes (1995), Lowen, Bartrina, Clay & Tobias (1996), Madroño, Clay *et al.* (1997), Mazar Barnett & Pearson (2001), Narosky *et al.* (1983), Navas & Bó (1988), Olrog (1963a), Parker & Goerck (1997), de la Peña (1988), Pinto (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Silva (1997), Stotz *et al.* (1996), Straube & Bornschein (1991b).

## 114. Pallid Spinetail

### *Cranioleuca pallida*

**French:** Synallaxe pâle **German:** Minas Gerais-Baumschlüpfer **Spanish:** Curutié Pálido

**Taxonomy.** *Synallaxis pallidus* Wied, 1831, Campos Geraes = southern Minas Gerais, Brazil.

Possible relationship to the *C. curtata* superspecies proposed by some authors on basis of plumage, vocalizations and montane distribution. Others suggest that it is part of a superspecies that includes *C. subcristata*, *C. pyrrhophia*, *C. henricae*, *C. obsoleta*, *C. albicapilla*, *C. antisiensis* and *C. baroni*, but genetic data suggest that at least the last two of those are not part of this lineage. Monotypic.

**Distribution.** SE Brazil, from C Minas Gerais and SE Bahia S to E Paraná.

**Descriptive notes.** 14-15 cm; 11-12 g. A *Cranioleuca* with colour pattern superficially like that of *Synallaxis*. Has prominent whitish supercilium, blackish spot in front of eye, dark brown postocular band, mainly buffy auriculars faintly flammulated with dark brownish; forehead streaked blackish and buff, central crown rather dark rufous, nape drab grey, blending to tawny-olive or olive-brown on hindneck to rump; rufous greater and median wing-coverts, dull dark brown primary coverts, pale cinnamon-tawny to rather pale warm olive-tawny remiges; tail graduated, rectrices with stiffened shafts, primarily at base, distal 1-5 mm devoid

of barbs or nearly so, giving very "spiked" appearance, dark rufous; chin buffy whitish, blending to bright buffy brownish-olive throat and breast, then to duller pale brownish-olive belly, slightly darker flanks and undertail-coverts; iris reddish-brown to pale brown; upper mandible black to dusky horn, lower mandible pinkish with dusky tip; tarsus and toes greenish-olive or grey with bluish and greenish-yellow tones. Sexes alike. Juvenile is darker on back, lacks rufous crown, has underparts tinged ochraceous, variable degree of dark mottling on breast. **Voice.** Song an accelerating series of clear whistled "psi" terminating in rolled "psrrrrr", sometimes repeated, and sometimes mixed with more melodious notes; call described as "tééé-ssik, tséé-ssik".

**Habitat.** Montane evergreen forest; also woodland, and tall second growth; 700-2150 m.

**Food and Feeding.** Arthropods. Forages most often in pairs, usually in mixed-species flocks, from mid-storey up to canopy. Hitches along small branches, often hanging upside-down acrobatically; gleans items from vine foliage, dead leaves, bark and debris.

**Breeding.** Season presumed to be during austral spring-summer. Presumably monogamous. Nest a globular mass of mainly lichen and moss, entrance towards lower side, bending tunnel leading upwards to small, unlined nest-chamber, placed against trunk of tree or on upper surface of branch in clumps of epiphytic vegetation. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. Fairly common in Itatiaia National Park and uncommon in Augusto Ruschi Biological Reserve; occurs also in Serra dos Órgãos National Park. Extensive deforestation within its relatively small range has dramatically reduced available habitat.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Avanzo & Sanfilippo (2000), Cordeiro (2001), Cory & Hellmayr (1925), Dunning (1993), Ferreira de Vasconcelos & Melo-Júnior (2001), García *et al.* (1999), Gonzaga *et al.* (1995), Ihering (1914), Mitchell (1957), Pacheco *et al.* (1996a), Parker & Goerck (1997), Pinto (1978), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Willis & Oniki (1991).

## 115. Grey-headed Spinetail

### *Cranioleuca semicinerea*

**French:** Synallaxe à tête grise **German:** Graukopf-Baumschlüpfer **Spanish:** Curutié Cabecigrís  
**Other common names:** Pale-headed Spinetail

On following pages: 116. Creamy-crested Spinetail (*Cranioleuca albicapilla*); 117. Red-faced Spinetail (*Cranioleuca erythrops*); 118. Tepui Spinetail (*Cranioleuca demissa*); 119. Streak-capped Spinetail (*Cranioleuca hellmayri*); 120. Ash-browed Spinetail (*Cranioleuca curtata*); 121. Line-checked Spinetail (*Cranioleuca antisiensis*); 122. Baron's Spinetail (*Cranioleuca baroni*); 123. Speckled Spinetail (*Cranioleuca gutturata*); 124. Scaled Spinetail (*Cranioleuca muelleri*); 125. Yellow-chinned Spinetail (*Certhiaxis cinnamomeus*); 126. Red-and-white Spinetail (*Certhiaxis mustelinus*).

suffusion, crown reddish-chestnut, back rich brown, becoming increasingly rufescent towards uppertail-coverts; wings reddish-chestnut, remiges slightly paler and with dark fuscous tips; tail graduated, rectrices with stiffened shafts (primarily basally), pointed tips, distal 1-2 mm sometimes without barbs (possibly through wear), dark reddish-chestnut; chin and throat whitish, underparts grey, flanks slightly browner; iris chestnut; upper mandible dusky brown to black, lower mandible pinkish-horn with dark tip; tarsus and toes olive-yellow to olive-brown. Distinguished from very similar *C. curtata* mainly

by much greyer underparts. Sexes alike. Juvenile lacks rufous on crown, has back more olivaceous brown, underparts more ochraceous. Race *cardonai* described as differing from nominate in having underparts olivaceous brown, rather than greyish, and supercilium and auriculars also more olivaceous. VOICE. Song a thin, descending, accelerating series, "tée-tée-te-ti ti' ti' ti' ti' ti' ti' ti' i", alarm a rattle.

**Habitat.** Montane evergreen forest; also gallery forest locally in Bolivar (Gran Sabana); 1100-2450 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks, from mid-storey to canopy. Hitches and climbs along small branches and through vines; acrobatically gleans items from bark and debris.

**Breeding.** Nest a globular mass of moss, partially suspended from branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Tepuis EBA. Fairly common within its limited range.

**Bibliography.** Anon. (2003d), Barnett *et al.* (2002), Chapman (1931), García *et al.* (1999), Hilty (2003a), Mayr & Phelps (1967, 1971), Phelps & Dickerman (1980), Pinto (1978), Renjifo *et al.* (1997), Ridgely & Tudor (1994), Rodner *et al.* (2000), Sick (1993, 1997), Snyder (1966), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Thomas (1990), Vaurie (1971d), Willard *et al.* (1991).

## 119. Streak-capped Spinetail

### *Cranioleuca hellmayri*

**French:** Synallaxe des broméliades

**German:** Santa Marta-Baumschlüpfer

**Spanish:** Curutié de Santa Marta

**Taxonomy.** *Siptornis hellmayri* Bangs, 1907, Páramo de Macotama, 11,000 feet [c. 3350 m], Sierra Nevada de Santa Marta, Colombia.

Forms a superspecies with *C. erythrops*, *C. demissa*, *C. curtata*, *C. antisimensis* and *C. baroni*; all share plumage similarities and mostly lower montane distribution, and their close relationship is consistent with recent genetic data. Some authors have proposed that it is more closely related to *C. suberistata* and *C. pyrrhophia*, because of streaked crown. Monotypic.

**Distribution.** Santa Marta Mts of N Colombia; one specimen from extreme NW Venezuela (Perijá Mts).

**Descriptive notes.** 14-15 cm; 14-16 g. Has narrow whitish supercilium; rest of face flammulated dark brownish and buff; crown reddish-chestnut with blackish streaks, hindcrown to back brown, blending to paler rump, uppertail-coverts tawny rufescent; wings mostly reddish-chestnut, remiges with slightly duller edges and dark fuscous tips; tail graduated, rectrices with shafts stiffened basally, tips pointed, reddish-chestnut; chin whitish, blending to pale brownish-grey or greyish-olive breast and belly, flanks and undertail-coverts slightly deeper and browner in colour; iris pale yellow to whitish; upper mandible blackish to

grey, lower mandible pinkish-horn to pinkish; tarsus and toes yellowish-green to flesh-coloured. Sexes alike. Juvenile undescribed. Differs from *C. curtata* mainly in streaking on crown and face. VOICE. Song not fully described, reported as similar to that of *C. curtata*; call a weak, high-pitched, squeaky trill, "ti, ti, ti, t-t-t-t".

**Habitat.** Montane evergreen forest and secondary forest; 1520-3000 m.

**Food and Feeding.** Arthropods. Forages mostly in pairs, usually in mixed-species flocks, from mid-storey up to subcanopy. Hitches along small branches; acrobatically gleans food items from bark, epiphytes (including bromeliads) and debris.

**Breeding.** Eggs in Sept-Nov. Presumably monogamous. Nest a ball of grass and leaves hanging from branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Santa Marta Mountains EBA. Common within limited geographical range. Status in Venezuela uncertain; the single record, of a female at R Palmer (Sierra de Perijá), was at 700 m, well below the elevational range within which the species occurs in Colombia.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), García *et al.* (1999), Hilty (2003a), Hilty & Brown (1986), Orejuela (1985), Remsen (2003a), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1980a).

## 120. Ash-browed Spinetail

### *Cranioleuca curtata*

**French:** Synallaxe à sourcils gris

**German:** Graubrauen-Baumschlüpfer

**Spanish:** Curutié Cejigris

**Other common names:** Fork-tailed Spinetail ("C. *furcata*")

**Taxonomy.** *Synallaxis curtata* P. L. Slater, 1870, "Bogotá".

Considered conspecific with *C. demissa* by some authors. The two are part of a superspecies that also includes *C. erythrops*, *C. hellmayri*, *C. antisimensis* and *C. baroni*; all share plumage similarities and mostly lower montane distribution, and their close relationship is consistent with recent

genetic data. Named taxon *furcata*, described (from N Peru) as a separate species, has been shown to be referable to immature plumage of present species. Race *cisandina* was formerly considered a separate species; proposed race *griseipsectus*, from E Ecuador, considered indistinguishable from latter. Three subspecies recognized.

**Subspecies and Distribution.**

*C. c. curtata* (P. L. Slater, 1870) - E Andes of Colombia (W slope from SE Santander S to Huila). *C. c. cisandina* (Taczanowski, 1882) - E Andes of S Colombia (S from W Caquetá), E Ecuador and N Peru (S at least to Pasco).

*C. c. debilis* (Berlepsch & Stolzmann, 1906) - Andes from C Peru (S from Ayacucho and Cuzco) S to C Bolivia (S to W Santa Cruz).

**Descriptive notes.** 14-15 cm; 14-21 g. Rather dark *Cranioleuca*. Nominative race has variable pale supercilium, from almost whitish and conspicuous to dingy grey and obscure; rest of face dull brownish, faint pale shaft streaks on auriculars; forehead brown with variable amount of reddish-chestnut suffusion, crown reddish-chestnut; back rich brown, becoming increasingly reddish towards uppertail-coverts; wings reddish-chestnut, with remiges slightly paler and with dark fuscous tips; tail graduated, rectrices with stiffened shafts primarily towards base, pointed tips, distal 1-2 mm sometimes without barbs (possibly through abra-

sion), dark reddish-chestnut; chin very pale dull brownish-grey, blending to browner throat with hint of streaking, then to dull brownish underparts, slightly richer brown on flanks; iris chestnut to brown (but field observations suggest that iris possibly white in nominate race); upper mandible dark brown to blackish, lower mandible pinkish with usually dark tip; tarsus and toes olive-greenish to mustard-yellow. Distinguished from very similar *C. demissa* mainly by much browner, less grey, underparts. Sexes alike; potential difference in extent of chestnut on forehead (male tends to have more, but sample size small) requires investigation. Juvenile has strong supercilium, crown like back but mixed with chestnut, rarely completely chestnut (variation evidently responsible for naming "*furcata*"), underparts below chin entirely ochraceous rufous. Race *cisandina* has crown, wings and tail darker, more chestnut, back darker brown, breast with darker greyish tones; *debilis* is like previous, but crown and back slightly paler, underparts paler and brighter, forecrown tends to be solidly chestnut, also significantly smaller in size than equatorial populations of latter. VOICE. Song a high-pitched, accelerating, descending and fading series of shrill notes with bouncing-ball rhythm (very similar to that of *C. erythrops*), c. 2 seconds long; also longer song, c. 5 seconds, that starts more slowly. Call undescribed.

**Habitat.** Montane evergreen forest and humid lower montane forest; mainly 900-1700 m, locally down to 650 m and as high as 2500 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks, from mid-storey to canopy. Hitches along small branches, occasionally hanging upside-down acrobatically. Gleans from and probes in bark, moss, epiphytes, dead leaves and debris.

**Breeding.** Fledgling in Mar in N Ecuador. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common; frequently overlooked, and possibly more common.

**Bibliography.** Bond (1945), Chapman (1926), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Foster *et al.* (1994), García *et al.* (1999), Graves (1985, 1986), Hilty & Brown (1986), Koepeke (1961b), Mayr & Phelps (1967), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen (2003a), Remsen & Ridgely (1980), Remsen & Traylor (1983, 1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman *et al.* (1999), Schulenberg (2002), Stotz *et al.* (1996), Taczanowski (1884), Traylor (1958), Vaurie (1971c).

## 121. Line-cheeked Spinetail

### *Cranioleuca antisimensis*

**French:** Synallaxe grimpeur

**German:** Olivrücken-Baumschlüpfer

**Spanish:** Curutié Cariestriado

**Other common names:** Northern Line-cheeked Spinetail, Fraser's Spinetail

**Taxonomy.** *Synallaxis antisimensis* P. L. Slater, 1859, Cuenca, Azuay, Ecuador.

Sister-species to *C. baroni*, and very likely conspecific; although populations at extremes of ranges are clearly different, the two grade into one another in step-clinal manner, making it difficult or impossible to determine to which taxon certain populations should be assigned (see page 187), this applying also to an apparently undescribed population in Amazonas (N Peru); thorough, quantitative analysis of all parameters (including plumage, morphometrics, vocalizations, genetics) required in order to elucidate the situation with regard to geographical differentiation and speciation. Both are part of a superspecies that also includes *C. erythrops*, *C. demissa*, *C. hellmayri* and *C. curtata*; all share plumage similarities and mostly lower montane distribution, and their close relationship is consistent with recent genetic data. Some authors, however, have considered them to belong to a superspecies that also includes *C. suberistata*, *C. pyrrhophia*, *C. henricae*, *C. obsoleta*, *C. pallida* and *C. albicapilla*, but such a relationship is not supported by recent genetic findings. Two subspecies recognized.

**Subspecies and Distribution.**

*C. a. antisimensis* (P. L. Slater, 1859) - Andes of SW Ecuador (N Azuay, El Oro, Loja).

*C. a. palamblae* (Chapman, 1923) - Andes of N Peru (Piura and Cajamarca S to N Lambayeque).

**Descriptive notes.** 14-15 cm; 14-19 g. Rather typical *Cranioleuca* without distinctive features. Nominative race has whitish supercilium, broad dark brown postocular stripe; rest of face buff-brown with few faint streaks; crown dark rufous, back dull brown, blending to rufous tips of uppertail-coverts; wings mainly dark rufous, tips of remiges dull fuscous, outer primaries dull fuscous with rufous edges basally on outer webs; tail graduated, rectrices stiffened basally, pointed at tips, dark rufous; throat pale greyish-white, blending to pale buffy grey-brown on breast, becoming duller and darker on belly; flanks and undertail-coverts

washed brownish; iris chestnut to light brown; upper mandible blackish to grey, lower mandible

pinkish-grey to pinkish; tarsus and toes olive to brownish-grey. Sexes alike. Juvenile is uniform dark brown above, sometimes some rufous on forecrown, underparts variably more mottled and more buff than adult. Race *palambae* has whiter supercilium, whitish streaks on auriculars, more greyish-olive back, whiter throat, slightly greyer underparts. VOICE. Song a loud, descending and fading series of sharp notes, lasting 1-1.5 seconds, seemingly differing to a degree from that of *C. baroni*; also longer (up to 6 seconds), more irregular song, sometimes ending with series of long, loud notes. Contact call "tsi-chik".

**Habitat.** Montane evergreen forest; humid to semi-humid montane forest and second growth, also hedgerows in agricultural areas; mainly 1000-2800 m, locally down to 900 m and up to 2900 m.

**Food and Feeding.** Arthropods. Forages singly, in pairs, or in small groups, regularly with mixed-species flocks, from canopy to mid-storey. Hitches along small branches, occasionally also small tree trunks; acrobatically gleans items from epiphytes, mosses and bark.

**Breeding.** Fledglings in Aug in Ecuador. Presumably monogamous. Nest a globular mass of mainly moss, suspended from a branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. Tolerates moderate anthropogenic habitat disturbance.

**Bibliography.** Chapman (1923, 1926), Cook (1996), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), García *et al.* (1999), Koepcke (1958, 1961a, 1961b, 1970), Maijer & Fjeldså (1997), Parker (1981), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1980a).

## 122. Baron's Spinetail

### *Cranioleuca baroni*

**French:** Synallaxe de Baron **German:** Weißbrauen-Baumschläpfer **Spanish:** Curutié de Baron  
**Other common names:** Southern Line-cheeked Spinetail

**Taxonomy.** *Siptornis baroni* Salvin, 1895. Huamachuco, La Libertad, and Cajabamba, Cajamarca, Peru.

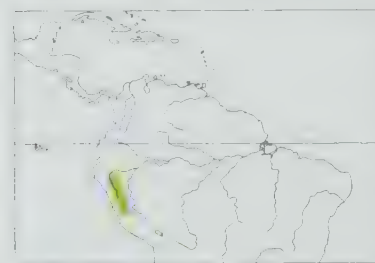

Sister-species to *C. antisensis*, and very likely conspecific; although populations at extremes of ranges are clearly different, the two grade into one another in step-clinal manner, making it difficult or impossible to determine to which taxon certain populations should be assigned (see page 187), this applying also to an apparently undescribed population in Amazonas (N Peru); thorough, quantitative analysis of all parameters (including plumage, morphometrics, vocalizations, genetics) required to elucidate the situation with regard to geographical differentiation and speciation. Both form a superspecies together with *C. erythrops*, *C. demissa*, *C. hellmayri* and *C. curtata*; all share plumage similarities and mostly lower montane distribution, and their close relationship is consistent with recent genetic data. Some authors, however, have considered them to belong to a superspecies that also includes *C. subcristata*, *C. pyrrhophia*, *C. henricae*, *C. obsoleta*, *C. pallida* and *C. albicapilla*, but such a relationship is not supported by recent genetic findings. Size variation among populations of present species substantial but somewhat irregular, correlated strongly with elevation, e.g. in Ancash birds of high elevations in N are much larger than low-elevation ones in S. Moreover, inter-locality variation is extraordinary; virtually every population sample seemingly diagnosable on basis of size and plumage characters, and many at least as distinctive as are currently accepted races. Three subspecies tentatively recognized.

**Subspecies and Distribution.**

*C. b. baroni* (Salvin, 1895) - Andes of N & C Peru (C Cajamarca and S Amazonas S to La Libertad, Ancash and WC Huánuco).

*C. b. capitalis* J. T. Zimmer, 1924 - Andes of C Peru (E Huánuco, Pasco).

*C. b. zaratensis* Koepcke, 1961 - Andes of WC Peru (Lima).

**Descriptive notes.** 15-19 cm; 19-32 g. The largest *Cranioleuca*. Nominat race has conspicuous white supercilium; rest of face dark grey-brown, variably flammulated buff-whitish; forehead a mix of reddish-brown and dark streaking that covers whitish supraloral spots, crown rufous-chestnut; back dark greyish-brown to brownish-grey or olive-grey, slightly paler on rump and uppertail-coverts; wings dark reddish-chestnut, remiges with dark dusky tips; tail graduated, rectrices with shafts stiffened basally, pointed tips, rufous-chestnut; throat and upper breast white, lower breast and sides dull brownish-grey with blurry buff-whitish streaks, which become narrow and faint on belly; flanks and undertail-coverts greyish-brown with faint pale shaft streaking; iris chestnut to greyish-brown (source of variation unknown); upper mandible black to dark grey, lower mandible pinkish to white, sometimes with dark tip; tarsus and toes olive to greyish-yellow. Sexes alike. Juvenile has supercilium greyish-buff, upperparts olive-grey with variable amount of rufous in crown, variable amount of dark scaling below, and often dusky spots on tips of central rectrices. Race *capitalis* described as having paler crown (variable, not always paler), distinct white shaft spots on sides of neck and breast, darker and greyer belly; *zaratensis* is similar to previous but much smaller, has more pointed tail feathers, central rectrices lacking barbs on distal 3-5 mm. VOICE. Song a loud, shrill descending series 1-4 seconds long, described as "quick-quick-quick-he-e-e-e-e" or "keek, kéék, kee-keekerrrrrr" with first note lower than rest, sometimes continued and repeated, reported to differ to a degree from that of *C. antisensis*. Call described as sharp, metallic "tec" or "tete".

**Habitat.** Semi-humid to semi-arid montane woodland, often with alders (*Alnus*); locally in *Polylepis* woodland. Mostly 2300-3700 m; locally down to 1700 m and up to 4500 m.

**Food and Feeding.** Arthropods; Lepidoptera larvae recorded in diet. Forages singly, in pairs, or in flocks of up to 10 individuals, occasionally with mixed-species flocks; from mid-storey to canopy. Hitches along small branches. Acrobatically gleans arthropods from epiphytes, mosses, dead leaves and bark, often in dense vegetation.

**Breeding.** Fledgling in Apr. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. No known potential threats within elevational range occupied by this species.

**Bibliography.** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), García *et al.* (1999), Koepcke (1954, 1961b, 1970), Maijer & Fjeldså (1997), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stotz *et al.* (1996), Zimmer (1924, 1930).

## 123. Speckled Spinetail

### *Cranioleuca gutturala*

**French:** Synallaxe ponctué **German:** Fleckenbrust-Baumschläpfer **Spanish:** Curutié Jaspeado  
**Other common names:** D'Orbigny's Spinetail

**Taxonomy.** *Anabates guttatus* d'Orbigny and Lafresnaye, 1838, Yuracarés (probably Cochabamba), Bolivia.

Relationships uncertain; differs vocally from other species in genus as currently defined. Possible sister-species relationship to *C. muelleri* suggested by plumage pattern. Proposed race *peruviana*, from E Peru, described as darker above, paler and less ochraceous below (including underwing-coverts), breast spotting coarser, chin paler yellow, supercilium less pronounced; these characters considered by subsequent authors to represent individual variation, although absence of buff wash on underparts thought by some to permit diagnosis; even if characters do represent geographical variation, however, specimens from C Peru seem intermediate. Further study may also demonstrate that resurrection of name *hyposticta* (type locality R Negro, opposite Boavista, in Brazil) for populations of NW Amazonia is warranted. Clearly, reanalysis of variation throughout range is required, and this may indicate that one or both are valid taxa. Tentatively treated as monotypic.

**Distribution.** SE Colombia (S from W Caquetá), S Venezuela (Amazonas, Bolívar), NE Surinam and N French Guiana S to E Ecuador, E Peru, Amazonian Brazil (W Amazonas E to Amapá, S to Acre and NC Pará) and N Bolivia (S to Cochabamba).

**Descriptive notes.** 13-15 cm; 13-17 g. The only *Cranioleuca* with spotted underparts and with rounded rectrix tips. Face and supercilium are ochraceous brown, freckled with dark brownish (especially auriculars); crown mostly dark chestnut, becoming dull dark brown on hindercrown and upper back, blending to richer brown lower back and rufescent-tinged brown rump and uppertail-coverts; wings dark chestnut, except for ochraceous bend of wing and dark fuscous tips of remiges; tail graduated, rectrices stiffened basally, tips rounded, rufous; chin dull yellow; throat and breast tawny-buff with conspicuous dark brown triangular spotting, belly, flanks and undertail-coverts with duller, fainter spots; iris pale yellowish to brown (source of variation unknown); upper mandible black to grey, lower mandible grey to blue-grey, often pinkish at base; tarsus and toes olive to brownish-yellow. Sexes alike. Juvenile lacks chestnut crown, has greyish-olive back; two different types (possibly stages) reported, one with underparts more greyish and spots paler and less distinct, the other with underparts washed ochraceous and no spots other than some dark margins on breast feathers. VOICE. Song a quavering, descending trill with introductory note, "tch-t-t-t-t-t-t-t-t", c. 2 seconds long; also a series of 5-7 very high-pitched, piercing "tsee" notes, often ending with spurts of lower sputtering trilled notes.

**Habitat.** Flooded evergreen forest and tropical lowland evergreen forest; mainly *várzea* forest and transitional forest, locally in poorly drained or streamside *terra firme* forest; usually in areas with dense vines. Mainly below 400 m, locally to 1100 m.

**Food and Feeding.** Diet consists primarily of cockroaches (Blattodea) and Heteroptera; Coleoptera and spiders also recorded. Forages singly or in pairs, usually in mixed-species flocks, from mid-storey to subcanopy. Hitches and hops along branches and small trunks; acrobatically gleans and probes for arthropods. Dead-leaf specialist; in SE Peru, 70% of foraging manoeuvres directed at dead leaves. Also obtains items from moss, epiphytes, palm fronds and debris.

**Breeding.** Nest-building in mid-Aug. in Peru. Presumably monogamous. Nest a cone-shaped mass of moss 25 cm long, tapering to entrance hole, suspended from branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to fairly common; often overlooked. Occurs in Manu National Park and Biosphere Reserve, in Peru.

**Bibliography.** Angehr & Aucca (1997), Bond (1945), Chapman (1926), Cory & Hellmayr (1925), Foster *et al.* (1994), García *et al.* (1999), Gyldenstolpe (1945a, 1945b, 1951), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee (1951), Munn (1985), Oren & Parker (1997), Parker & Bailey (1991), Parker *et al.* (1982), Remsen (2003a), Remsen & Parker (1983, 1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson *et al.* (1990), Rodner *et al.* (2000), Rosenberg (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992), Zimmer, Parker *et al.* (1997).

## 124. Scaled Spinetail

### *Cranioleuca muelleri*

**French:** Synallaxe écaillé **German:** Schuppenbauch-Baumschläpfer **Spanish:** Curutié Escamoso

**Taxonomy.** *Siptornis mülleri* Hellmayr, 1911, Fazenda Nazareth, Mexiana Island, Brazil.

Plumage pattern suggests that sister-species may be *C. gutturala*. Monotypic.

**Distribution.** R Amazon in Brazil, from extreme E Amazonas E to S Amapá and Mexiana I.

**Descriptive notes.** 14-15 cm; 14-15 g. Dark *Cranioleuca* with scaly-looking underparts, giving juvenile-like appearance. Has narrow pale supercilium, dull brownish face faintly flammulated; forehead dark brown, crown dark reddish-chestnut, back rich dark brown, rump brown; wings mostly dark reddish-chestnut; tail graduated, rectrices stiffened basally, pointed at tips, dark chestnut; chin pale greyish, faintly scaled, becoming darker and more heavily scaled on throat; breast and belly very pale buff-brown with dark brown feather tips, creating scaled appearance; flanks and undertail-coverts brown; iris brown; upper mandible blackish at base, blending to pale tip, lower mandible pale pinkish-grey with yellowish base; tarsus and toes olive-tinged yellow-green. Sexes alike. Juvenile has uniform upperparts with hint of ochraceous collar, scaling of underparts tinged ochraceous, feathers with broader dark tips. VOICE. No information.

**Habitat.** Flooded tropical evergreen forest, mainly undergrowth of *várzea* forest; 0-200 m.

**Food and Feeding.** Arthropods. Forages usually in pairs, often in mixed-species flocks, from undergrowth to mid-storey. Hitches along small branches; acrobatically gleans items from bark and debris.

**Breeding.** No information; only unconfirmed mention of nest as a globular mass of sticks and placed in tree.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Amazon Flooded Forests EBA. Poorly known species; population thought likely to be relatively small.

**Bibliography.** Cohn-Haft (2003a), Cory & Hellmayr (1925), García *et al.* (1999), Pinto (1978), Remsen (2003a), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Whitney *et al.* (1996).

## Genus *CERTHIAXIS* Lesson, 1844

### 125. Yellow-chinned Spinetail

#### *Certhiaxis cinnamomeus*

**French:** Synallaxe à gorge jaune

**German:** Gelbkinn-Riedschlüpfer

**Spanish:** Curutié Colorado

**Other common names:** Yellow-throated Spinetail

**Taxonomy.** *Certhia cinnamomea* J. F. Gmelin, 1788, no locality = Cayenne.

Some authors include *Cranioleuca* in present genus because of general morphological similarities, but most treat them as separate genera because of differences in nest structure. Birds from NE Colombia (N Arauca) assumed to belong to race *marabinus*, and those from W part of R Amazon (E to R Negro) tentatively placed with *pallidus*; further study needed. Proposed race *albescens*, described from Carabobo, in N Venezuela, is a synonym of *valencianus*. Eight subspecies recognized.

**Subspecies and Distribution.**

*C. c. fuscifrons* (Madarász, 1913) - N Colombia (R Atrato E to base of Santa Marta Mts, also lower Cauca Valley and most of Magdalena Valley).

*C. c. marabinus* Phelps, Sr. & Phelps, Jr., 1946 - NW Venezuela (Zulia W of L Maracaibo, and W Trujillo, W Mérida and NW Táchira) and NE Colombia (N Arauca).

*C. c. valencianus* J. T. Zimmer & Phelps, Sr., 1944 - WC Venezuela (Lara, Portuguesa and Barinas E to Aragua and Guárico).

*C. c. orenocensis* J. T. Zimmer, 1935 - lower Orinoco Valley in Venezuela (S Apure, SE Guárico, N Amazonas, and N Bolívar E to S Sucre and Delta Amacuro).

*C. c. cinnamomeus* (J. F. Gmelin, 1788) - Trinidad, NE Venezuela (N Sucre, N Anzoátegui), the Guianas and NE Brazil (Pará E to N Maranhão).

*C. c. pallidus* J. T. Zimmer, 1935 - extreme SE Colombia (SE Amazonas) and W & C Amazonian Brazil (E, including lower R Negro and lower R Purús, to lower R Tocantins).

*C. c. cearensis* (Cory, 1916) - E Brazil (S Maranhão, Ceará, Piauí, Pernambuco, N Bahia).

*C. c. russeolus* (Vieillot, 1817) - E Bolivia (S from Pando), S Brazil (C Mato Grosso E to S Bahia, and S to Rio Grande do Sul), Paraguay, N Argentina (S to Salta, NE Córdoba and N Buenos Aires) and Uruguay.

**Descriptive notes.** 13-16 cm; 13-17 g. A crisply patterned spinetail mainly reddish above and whitish below. Nominative race has grey supercilium, broad dusky brown eyeline, greyish rest of face; crown reddish-brown, becoming slightly paler on back; rump paler rufescent brown, long uppertail-coverts darker and redder; wings bright rufous, dark fuscous tips of remiges; tail graduated, 12 rectrices with stiffened shafts, distal 5-10 mm nearly lacking in barbs, producing very "spiny" appearance, mostly rufous, central pair with duller brown inner webs; chin and centre of upper throat pale yellow, rest of throat white; breast and belly creamy white, sides pale grey-

brown, flanks and undertail-coverts tawny brownish; iris reddish-brown to pale orange to whitish (source of variation unknown, possibly geographical); upper mandible blackish, lower mandible uniform black to grey with black tip; tarsus and toes bluish to greyish to silvery slate. Differs from similar *C. mustelinus* mainly in having pale supercilium, yellow on throat, 12 rather than 10 rectrices. Sexes alike. Juvenile lacks yellow on chin, has darker and less rufescent upperparts, underparts occasionally faintly mottled. Race *fuscifrons* has dusky brown forehead; *marabinus* has the most reddish upperparts of any race, differs from nominate also in having dusky greyish forehead, whiter supercilium; *valencianus* differs from previous in less reddish upperparts, darker, more dusky underparts, greyish supercilium; *orenocensis* is palest, dullest, least rufescent race, with back sandy brown, contrasting with wings and crown, also dusky spot on distal portion of inner webs of central rectrices; *pallidus* is evidently like last but brighter rufescent above, and much paler throughout than nominate; *cearensis* is like previous but brighter generally, has darker sides and flanks; *russeolus* is like last, but has browner, less rufescent upperparts, more greyish flanks and undertail-coverts. **Voice.** Sings frequently; churring rattle, "chu-chu-chehechehechehe", often as duet, also described as low-pitched trill 1-2 seconds long that ascends and then fades (reminiscent of song of a *Laterallus* rail); also gives short thin trill. Call a sharp "krip" or "chip".

**Habitat.** Freshwater marshes and edge of mangrove forest; found in a variety of wetlands with mix of grass, shrubs, and emergent and floating vegetation, including on old river islands in Amazonia; also overgrown ditches. Sea-level to 500 m, locally to 750 m. Locally syntopic with *C. mustelinus*, but habitat differences between them not clear.

**Food and Feeding.** Recorded dietary items are Coleoptera, Lepidoptera larvae, Hemiptera, Odonata, Hymenoptera including ants, Orthoptera, Diptera, Isoptera, spiders and 1 crab (*Uca thayeri*). Forages singly or in pairs, usually on or within 2 m of ground, occasionally to c. 3 m. Gleans arthropods from small branches and foliage, occasionally from water or ground.

**Breeding.** Breeds throughout year in coastal Surinam, and primarily during Aug-Oct dry season in French Guiana; active nests in Apr-Oct in W Venezuela; breeding recorded Jun-Oct (Jun peak in egg dates) in Trinidad; eggs in Oct in S Brazil; eggs in Oct-Dec and nestlings in Nov-Dec in Argentina. Presumably monogamous. Nest a bulky, globular mass c. 25-40 cm long, c. 20-30 cm high, made of interwoven sticks, often thorny ones, interior curving tube c. 20-25 cm long leading vertically from top or end to nest-chamber, latter c. 10 cm in diameter, sometimes lined with soft plant material; placed low in bush or grass, usually near or over water, 0.2-1.5 m up, rarely as high as 9 m, often between roots when in mangrove forest; new nest sometimes superimposed on old one. Clutch 2-5 eggs. Nests regularly parasitized by Striped Cuckoo (*Tapera naevia*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to abundant in much of its large range. Restriction to wetlands makes it susceptible to the usual suite of conservation problems that afflict wetland species, e.g. drainage and pollution. Occurs in numerous protected areas.

**Bibliography.** Anon. (2003d), Belcher & Smooker (1936), Belton (1984), Collins & Araya (2002), Contreras (1979d), Cory & Hellmayr (1925), Cuervo (1985), Ferreira de Vasconcelos & Melo-Júnior (2001), French (1991), Gyldenstolpe (1945b, 1951), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003a), Hilty & Brown (1986), Lefebvre *et al.* (1992), Melo-Júnior *et al.* (2001), Morton (1979), Narosky *et al.* (1983), Nores & Yzurieta (1981), Nores *et al.* (1983), Parker & Goerck (1997), Parker *et al.* (1982), Parrini *et al.* (1999), de la Peña (1987, 1988), Phelps & Phelps (1946), Pinto (1978), Pinto & Camargo (1952), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Roda (1991), Rodner *et al.* (2000), Rosenberg, G.H. ### 126. Red-and-white Spinetail

#### *Certhiaxis mustelinus*

**French:** Synallaxe belette

**German:** Weißbauch-Grasschlüpfers

**Spanish:** Curutié Rojiblanco

**Taxonomy.** *Synallaxis mustelina* P. L. Selater, 1874, Rio Madeira, below the mouth of the Rio dos Marmelos, Amazonas, Brazil.

Some authors include *Cranioleuca* in present genus because of general morphological similarities, but most treat them as separate genera because of differences in nest structure. Proposed race *frenatus* (from E Brazil) is not diagnosable. Monotypic.

**Distribution.** R Amazon and some major tributaries in NE Peru (S along R Ucayali), extreme SE Colombia (SE Amazonas) and Brazil (E to extreme E Pará, including lower R Juruá and lower R Purús, and S along R Madeira to near Bolivian border).

**Descriptive notes.** 14-15 cm; 14-16 g. Has black lores, dusky brown eyeline; reddish-brown face, crown and upperparts, slightly paler on back, rump paler rufescent brown; wings bright rufous, dark fuscous tips of remiges; tail graduated, 10 rectrices with stiffened shafts, distal 5-10 mm nearly lacking in barbs, producing very "spiny" appearance, mostly rufous, central pair with duller brown inner webs; chin and throat white; underparts white, belly, flanks and undertail-coverts washed pale buff; iris brown; upper mandible grey to blackish, lower mandible dark grey; tarsus and toes light grey. Differs from

similar *C. cinnamomeus* in black lores, no supercilium, no yellow on throat, 10 rather than 12 rectrices. Sexes alike. Juvenile has dusky crown, less uniformly rufous upperparts, faintly mottled breast. **Voice.** Song a short trill, rising and then falling, "ch-t-t-t-t-t-t-t-t-t-t"; call "chuk-chek" or "chuck-chuck-check", final note slightly higher-pitched.

**Habitat.** Freshwater marshes; primarily marshy sections of old river islands with mix of bushes, grass and emergent vegetation; from near sea-level to 150 m. Locally syntopic with *C. cinnamomeus*, but habitat differences between them not clear.

**Food and Feeding.** Arthropods. Forages singly or in pairs; gleans items from small branches and foliage, usually within 1 m of ground.

**Breeding.** Presumably monogamous. Nest a ball c. 40-50 cm in diameter, of thorny sticks, placed in low vegetation over water. No further information.

**Movements.** Probably resident; may potentially have to evacuate some river islands during high-water season.

**Status and Conservation.** Not globally threatened. Rare to uncommon. Owing to linear nature of habitat, global population almost certainly rather small. Occurs in Amacayacu National Park, in Colombia.

**Bibliography.** Cory & Hellmayr (1925), Gyldenstolpe (1945a, 1951), Hilty & Brown (1986), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Parker (1983), Ridgely & Tudor (1994), Rosenberg, G.H. (1990), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1958), Zimmer (1936a).

## Genus *THRIPOPHAGA* Cabanis, 1847

### 127. Striated Softtail

#### *Thriphopha macroura*

**French:** Synallaxe rayé **German:** Zimtschwanzcanastero **Spanish:** Colasuave Estriado

**Taxonomy.** *Anabates macrourus* Wied, 1821, Rio Catolê, Bahia, Brazil.

Possible close relationship of this species and *T. cherriei* to *Asthenes* suggested by some authors on basis of presence of throat patch. Monotypic.

**Distribution.** Coastal SE Brazil, from S Bahia S to N Rio de Janeiro.

**Descriptive notes.** 17-18 cm. Small furnariid with shape like *Cranioleuca* but patterned more like *Asthenes*. Has indistinct buff supercilium, pale lores, rest of face brownish with broad pale buff to tawny-buff streaks; crown and upperparts dark reddish-brown with conspicuous brown-bordered reddish-rufous to rufous buff shaft streaks; wings mostly dark rufous, remiges with dark fuscous tips; tail graduated, rectrices with shafts slightly stiffened basally, tips blunt, pale tawny to cinnamon-rufous; chin and upper throat orange-rufous to yellowish-orange; underparts dull brown, streaked buff, streaks fading on belly and undertail-coverts;

iris deep chestnut brown; upper mandible dusky horn to silvery grey, lower mandible bluish-grey with dusky horn tip; tarsus and toes dull greenish-grey. Sexes alike. Juvenile lacks throat patch, has less well-defined streaks on back, is more mottled than streaked below. **VOICE.** Song 1-2 well-spaced notes followed by burst of trilled notes, lasts c. 1.5 seconds; also descending series of "che" notes, as duet. Loud "kit-kit-kit" call.

**Habitat.** Tropical lowland evergreen forest, ranging, at least, into degraded forest patches; favours areas with dense vine tangles. From near sea-level to 1000 m.

**Food and Feeding.** Arthropods; recorded items include Orthoptera. Forages singly, in pairs, or in small groups (possibly family parties) of 3-5 individuals; usually in mixed-species flocks. Forages from understorey to subcanopy, usually in dense vine tangles but also in foliage and along branches. Gleans food items from vines, dead leaves, branches, trunks and foliage.

**Breeding.** Active nests found in Sept-Oct and Dec-Jan. Presumably monogamous. Nest a ball-shaped mass, c. 25-30 cm in diameter and 20-25 cm tall, made of grassy fibres and moss, or small twigs, and rootlets bound with fibres and moss, with vertical entrance tube c. 3-5 cm long on lower surface; placed in fork of small branches (perhaps woven to them) c. 10-25 m above ground on outer branches in tall, sometimes isolated tree; territory size evidently rather small, perhaps only 1.5 ha. Clutch 3 eggs.

**Movements.** Resident.

**Status and Conservation.** **1 NDANGERED.** Restricted-range species; present in Atlantic Forest Lowlands EBA. Rare to locally fairly common; possibly overlooked. Fairly common in Sooretama Biological Reserve; present in Desengano State Park. Population estimated at 2500-10,000 individuals; declining as a result of habitat destruction. Distribution within seemingly favourable habitat seems patchy. Evidently requires areas of dense vine tangles in tracts of tall forest, which have been almost eliminated in much of its range.

**Bibliography.** Aleixo *et al.* (1991), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cordeiro (2001), Cory & Hellmayr (1925), Lima *et al.* (2002), Mazar Barnett & Kirwan (2003), Pacheco *et al.* (1996a), Parker & Goerck (1997), Pinto (1935, 1938, 1978), Ridgely & Tudor (1994), Sick (1985c, 1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

### 128. Orinoco Softtail

#### *Thriphopha cherriei*

**French:** Synallaxe de l'Orénoque **German:** Strichelkehlcanastrero **Spanish:** Colasuave del Orinoco

**Taxonomy.** *Thriphopha cherriei* Berlepsch and Hartert, 1902, Rio Capuana, Rio Orinoco, Amazonas, Venezuela.

Possible close relationship of this species and *T. macroura* to *Asthenes* suggested by some authors on basis of presence of throat patch. Monotypic.

**Distribution.** SC Venezuela (NW Amazonas).

**Descriptive notes.** 15.5-17.5 cm. Has indistinct buff supercilium, rest of face brownish with pale buff streaks; forehead brown with short buff shaft streaks, crown medium brown, back rufescent brown, rump rufescent, upper-tail-coverts reddish-chestnut; wings mostly dark rufous-chestnut; tail rounded, rectrices slightly stiffened at base, rather rounded at tips, dark rufous; chin tawny-orange, upper throat chestnut-rufous, rest of throat and breast olive-brown with distinct buff streaks, blending to paler brown belly, darker flanks; undertail-coverts reddish-rufous; iris dark red; bill grey to blackish; tarsus and toes dull fleshy olive.

Sexes alike. Juvenile unknown. **VOICE.** No information.

**Habitat.** Dense understorey along streams and in adjacent *várzea* forest, at 120 m.

**Food and Feeding.** No information.

**Breeding.** No information.

**Movements.** Presumably resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Orinoco-Negro White-sand Forests EBA. Fairly common at its only known site, on R Capuana (right bank of R Orinoco); this included in Sipapo Forest Reserve, but whether this results in any real protection for riverine habitats is unknown. Reasons for this species' restriction to such a small area almost certainly lie in specialization on some unusual, local, type of riverine habitat; type locality described as rainforests and small clearings along riverbanks and small *caños*. No data on population size, trends, or specific threats. Main threat thought to be probably habitat loss caused by unsustainable practice of shifting cultivation.

**Bibliography.** Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1925), Hilty (2003a), Phelps & Phelps (1950), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

### 129. Plain Softtail

#### *Thriphopha fusciceps*

**French:** Synallaxe terne **German:** Rostflügelcanastrero **Spanish:** Colasuave Sencillo

**Taxonomy.** *Thriphopha fusciceps* P. L. Slater, 1889, mouth of Rio Chapare, 825 feet [c. 250 m], Cochabamba, Bolivia.

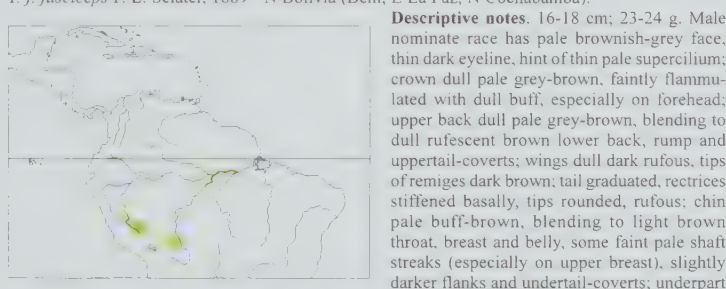

Placed in genus *Phacellodomus* by some authors. Races vary markedly in size; this, and the anomalous pattern of their distribution and unusual combination of habitats, could suggest that the three races are separate species; further research needed. Three subspecies recognized.

**Subspecies and Distribution.**

*T. f. dimorpha* Bond & Meyer de Schauensee, 1941 - E Ecuador (Napó) and SE Peru (Pasco, Junín, Cuzco, Madre de Dios, Puno).

*T. f. obidensis* Todd, 1925 - C Brazil (lower R Madeira, and C R Amazon in E Amazonas and Pará).

*T. f. fusciceps* P. L. Slater, 1889 - N Bolivia (Beni, E La Paz, N Cochabamba).

**Descriptive notes.** 16-18 cm; 23-24 g. Male nominate race has pale brownish-grey face, thin dark eyeline, hint of thin pale supercilium; crown dull pale grey-brown, faintly flammulated with dull buff, especially on forehead; upper back dull pale grey-brown, blending to dull rufescent brown lower back, rump and uppertail-coverts; wings dull dark rufous, tips of remiges dark brown; tail graduated, rectrices stiffened basally, tips rounded, rufous; chin pale buff-brown, blending to light brown throat, breast and belly, some faint pale shaft streaks (especially on upper breast), slightly darker flanks and undertail-coverts; underpart coloration variable, sometimes grey rather than brown; iris chestnut to burnt orange to greyish-lavender (source of variation unknown); upper mandible bluish-horn to pale grey, often darker around nostrils, lower mandible pale grey to pale bluish; tarsus and toes olive-green to yellowish-olive. Female reportedly has on average paler forehead and underparts. Juvenile is faintly mottled on throat and upper breast, less distinctly patterned. Race *dimorpha* is substantially smaller than nominate, coloration evidently quite variable but in general much darker, forehead contrasts less with crown, supercilium absent or indistinct, back darker and strongly rufescent, underparts darker and more rufescent (variable, browner or greyer); *obidensis* is a darker brown throughout than previous, and no variation in underpart coloration. **VOICE.** Song of nominate race begins with widely spaced, dry ticking notes, accelerating and rising to extremely high notes, then descends into bursts of sputtering tick notes, lasts as long as 25 seconds; often given as duet. Call undescribed.

**Habitat.** Flooded tropical evergreen forest and river-edge forest, mainly humid *várzea* and transitional forest, usually at edge or around treefalls, often where dense tangles of vines; also drier forest, deciduous forest. At 50-500 m.

**Food and Feeding.** Arthropods. Usually in pairs or small groups, often with mixed-species flocks. Forages from understorey up to subcanopy. Acrobatically gleans food items from dead leaves, debris and small branches, often within dense vine tangles; possibly a dead-leaf specialist.

**Breeding.** Nest a globular mass c. 20 cm in diameter, made from small twigs and soft plant material, with two short entrance tubes on lower side, placed in fork of small branches in canopy tree; single known nest of race *dimorpha* had two entrance tubes converging from above on interior nest-chamber, a novel construction within the family. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare and local; absent from many areas where habitat superficially seems suitable. Present in Manu National Park and Biosphere Reserve.

**Bibliography.** Bond & Meyer de Schauensee (1941), Chapman (1926), Cory & Hellmayr (1925), Foster *et al.* (1994), Mazar Barnett & Kirwan (2003), Pacheco *et al.* (1996a), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Parker (1984), Remsen & T aylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schmitt & Schmitt (1987), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Pequeño *et al.* (2002), Terborgh *et al.* (1984), Whitney *et al.* (1996), Zyskowski (2003), Zyskowski & Prum (1999).

### 130. Russet-mantled Softtail

#### *Thriphopha berlepschi*

**French:** Synallaxe mantelé **German:** Graustirncanastero **Spanish:** Colasuave Dorsirrufo

**Taxonomy.** *Thriphopha berlepschi* Hellmayr, 1905, Leimebamba, 10,000 feet [c. 3050 m], Amazonas, Peru.

Placed in genus *Phacellodomus* by some authors, whereas others suspect that it belongs in *Cranioleuca*. Differs from congeners in general plumage and montane distribution, but head pattern and bill coloration very similar to those of *T. fusciceps*. Monotypic.

**Distribution.** Andes of N Peru (Amazonas S to La Libertad).

**Food and Feeding.** Arthropods. Forages solitarily or in pairs, occasionally in mixed-species flocks. Gleans items from ground, possibly also from low vegetation.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Fairly common to uncommon; probably overlooked. Evidently tolerates at least moderate habitat disturbance and fairly heavy grazing; present in some agricultural areas. Not dependent on *Polylepis*; some populations, however, under pressure from clearance of such woodland for cultivation and exotic plantations, firewood-gathering, and burning to create pasture.

**Bibliography.** Anon. (2003c), Bond (1945), Chebez *et al.* (1999), Collar *et al.* (1994), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Majer (1996), Mazar Barnett & Pearman (2001), Mazar Barnett, Clark *et al.* (1998), Pearman (2001), Ridgely & Tudor (1994), Schulenberg & Awbrey (1997b), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1969).

## 134. Cordilleran Canastero

### *Asthenes modesta*

**French:** Synallaxe des rocailles **German:** Graslandcanastero **Spanish:** Canastero Pálido

**Taxonomy.** *Synallaxis modestus* Eyton, 1851. Bolivia (?).

Forms a superspecies with *A. cactorum*, and sometimes considered conspecific. Nominate race apparently varies clinally in back colour, darkest in N, palest and sandiest in S. Proposed race *navasi*, from S Argentina, described as differing from *australis* in biometrics (significantly shorter bill, longer wing and tail), but overlap in measurements prevents diagnosis of many specimens. Seven subspecies recognized.

**Subspecies and Distribution.**

*A. m. proxima* (Chapman, 1921) - Andes of C & S Peru (Junín S to Cuzco).

*A. m. modesta* (Eyton, 1851) - Andes of SW Peru (Arequipa, Puno) and W Bolivia (W La Paz, Oruro, Potosí) S to N Chile (Tarapacá, Antofagasta) and NW Argentina (Jujuy, Salta, Catamarca).

*A. m. rostrata* (Berlepsch, 1901) - C Bolivia (E slope in La Paz and Cochabamba).

*A. m. hilereti* (Oustalet, 1904) - Andes of NW Argentina (Sierra de Aconquija and Cumbres Calchaquies, in Tucumán and Catamarca).

*A. m. australis* Hellmayr, 1925 - C & S Chile (Andes from S Atacama S to Colchagua, lowlands in Aisén and N Magallanes) and W & S Argentina (Andes S from La Rioja, and lowlands from La Pampa, and Serranías de Ventania in SW Buenos Aires, S to Santa Cruz).

*A. m. serrana* Nores, 1986 - Cerro Famatina, in La Rioja (W Argentina).

*A. m. cordobae* Nores & Yzurieta, 1980 - Córdoba (Sierras Grandes, Sierra de Comechingones) and NE San Luis (Sierra de San Luis), in C Argentina.

rectrices tapered and somewhat pointed at tips, dark fuscous and rufous in varying proportions, from rufous confined to outer webs of central pair, to outer pair being almost completely rufous except for some dark fuscous at base of inner webs; malar region whitish buff-brown with darker brown streaks; chin and upper throat pale brownish with dark to pale orange-rufous (source of variation uncertain) feather bases forming "messy" throat patch; neck side, lower throat and upper breast whitish grey-brown with obscure darker streaking, rest of breast and belly pale brown, flanks and undertail-coverts tinged rufescent; iris brown to dark brown; upper mandible black to dark brownish-horn, lower mandible horn to brownish-grey with dark tip; tarsus and toes blackish-grey to dusky brown. Sexes alike. Juvenile lacks throat patch, has mottled breast and belly. Race *proxima* is like darker-backed nominate, but outer webs of rectrices paler, tawny-rufous rather than intense rufous; *rostrata* has darker upperparts, including central rectrices, and rufous in wings darker; *hilereti* has greyer back than nominate race or previous; *serrana* is like nominate, but underparts paler and greyer, less rufescent (but more ochraceous below and more rufescent above than previous); *cordobae* darker brown, less cinnamon, above and less cinnamon below than nominate, with wings and tail darker than other races; *australis* is greyer above than nominate, wing-coverts less rufescent, paler and less buffy underparts, also longer bill. VOICE. Song an ascending fast trill that ends abruptly, c. 2 seconds long; also more complex trill with introductory notes; in Argentina, described as "chichichi, chirí, chirí... chichichi, chirí, chirí". Call a short, low "pyup" or "tjit".

**Habitat.** Puna grassland, southern temperate grassland; arid to semi-humid grassland, often rocky and often with scattered low bushes, locally in arid montane scrub in S Argentina; also arid *Polylepis* thickets, scrub *Baccharis tola* scrub, and dry open woodland. From near sea-level to 4500 m.

**Food and Feeding.** Arthropods; recorded dietary items are Coleoptera, ants, cockroaches (Blattidae). Usually forages solitarily, occasionally in pairs. Gleans items from ground, also rarely from low vegetation.

**Breeding.** Season during austral spring-summer; eggs in Oct-Jan and nestlings in Nov and Feb in Argentina; eggs in Nov in Chile; fledglings in Apr in C Bolivia. Presumably monogamous. Nest a cylindrical or spherical mass of twigs, often thorny ones, tightly interwoven, often feathers and hair included, entrance hole on side, interior chamber c. 12-15 cm in diameter, lined with feathers and hair; placement exceptionally variable, sometimes 0.5-2 m up in bush, also on ground in rock crevice, in hole in dirt bank, among root clumps, or in abandoned nest of other bird. Clutch 2 eggs in Argentina, 3-4 in Chile.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in much of its range. Habitat occupied by this species is generally subjected to at least moderate overgrazing.

## 135. Cactus Canastero

### *Asthenes cactorum*

**French:** Synallaxe des cactus **German:** Kaktuscanastero **Spanish:** Canastero de los Cactus

**Taxonomy.** *Asthenes cactorum* Koepcke, 1959, Atico, Arequipa, Peru.

Forms a superspecies with *A. modesta*, and sometimes considered conspecific. Supposedly smaller birds from the *lomas* of Lachay region, having greyish-rose cast and very dark central rectrices with dark rufous webs, described as race *lachayensis*; those from higher Andes from Lima S to Arequipa proposed as race *monticola*, said to differ from birds of coastal *lomas* in larger size, browner (less ochre) upperparts, darker central rectrices, somewhat darker throat patch, and less uniform underparts with more contrasting darker sides and flanks; both populations, however, appear to be products of clinal variation combined with differences in degree of plumage wear, and described characters do not permit diagnosis of individual specimens. Monotypic.

**Distribution.** W slope of Andes of SW Peru (Lima S to Arequipa).

**Descriptive notes.** 13-14 cm; 16-19 g. Large-billed, rather dull canastero. Has dull pale buff supercilium behind eye, fuscous lores and postocular band, contrasting dull buff line above lores, dull buff auriculars faintly flammulated; crown and upperparts rather uniform plain dull brown; median and greater wing-coverts mostly dull rufous, remiges dull fuscous with rufous wingband; tail graduated, rectrices somewhat pointed, central pair gradually tapering, central pair dark brown but becoming dull brown (like upperparts) along margins, next two pairs dull dark fuscous with outer webs margined tawny, next pair rufous

except for dark fuscous margins basally, outer two pairs almost completely rufous; chin and centre of throat dull pale orange-tawny, blending to dull pale buff breast and rest of underparts; iris brown; upper mandible black to grey, lower mandible blue-grey with blackish tip; tarsus and toes grey-brown to black. Sexes alike. Juvenile undescribed. VOICE. Song a weak, dry trill lasting up to 6 seconds; call described as low-pitched, fast, dry trill 0.5-2 seconds long, often repeated.

**Habitat.** Arid montane scrub; arid slopes with sparse bushes, such as *Jatropha*, and columnar cacti; 50-2500 m.

**Food and Feeding.** Little known. Solitary or in pairs. Apparently gleans arthropods from ground, rocks, cacti, and perhaps low vegetation.

**Breeding.** Season mainly austral spring-summer; eggs in Oct-Jan (also Jun-Aug for "*lachayensis*"). Presumably monogamous. Nest in columnar cactus. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Peru-Chile Pacific Slope EBA. Uncommon. A poorly known species. Habitat is subjected to at least moderate overgrazing.

**Bibliography.** Fjeldså & Krabbe (1990), Koepcke (1959, 1963, 1970), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1980a).

## 136. Streak-throated Canastero

### *Asthenes humilis*

**French:** Synallaxe terrestre **German:** Streifenkehlcanastero **Spanish:** Canastero Gorgiestriado

**Taxonomy.** *Synallaxis humilis* Cabanis, 1873, Maraynioc, Junín, Peru.

Specimens from interior Andes of Junín and Lima (Peru), with pinkish wash below, may represent an undescribed race. Three subspecies recognized.

**Subspecies and Distribution.**

*A. h. cajamarcae* J. T. Zimmer, 1936 - Andes of NW Peru (S Cajamarca).

*A. h. humilis* (Cabanis, 1873) - Andes of C Peru (La Libertad and Ancash S to Huancavelica and Ayacucho).

*A. h. robusta* (Berlepsch, 1901) - Andes of S Peru (Cuzco S to Puno) and N Bolivia (La Paz, W Cochabamba).

**Descriptive notes.** 15-16 cm; 23-24 g. Typical canastero with coloured throat patch, some striping on head, medium-length tail. Nominative race has dull whitish-buff supercilium extending to bill base, dark brownish lores and vague postocular band, rest of face and side of neck streaked dark brown and greyish-buff; crown dark dull brown with vague dark shaft streaks, blackish spotting on forehead; upperparts dark dull brown, faint darker streaks on upper back becoming longer and broader towards lower back; wings mainly dull dark brownish, wing-coverts partly rufous, rufescent margins of some secondaries; tail gradu-

ated, central pairs of rectrices tapering, somewhat pointed, feathers dark brown with tawny-buff margins on outer webs; chin orange-rufous, blending to dull pale brown throat and underparts, belly paler, flanks and undertail-coverts warmer brownish-buff (underparts washed clay-pinkish in interior Peruvian Andes in Junín and Lima), narrow blackish streaks on throat fading and paling on upper breast; iris brown; upper mandible black to dark horn, lower mandible blackish to grey with black tip; tarsus and toes greyish-olive to brownish-grey. Sexes alike. Juvenile has faint or no orange on throat, less distinct streaks, more prominent rufous markings in tail. Race *cajamarcae* is greyer above with more distinct streaks, paler and less buffy below; *robusta* is like nominate, but darker back with less distinct streaks (reported characters of larger size, larger throat patch, more heavily blackish-marked neck and side of throat, greyish-edged inner rectrices not sustained in series of specimens). VOICE. Song described as a quavering, soft trill 2-5 seconds in duration; also gives doubled or tripled trill that lasts c. 1 second. Contact call a burst of "pit" notes, usually repeated 2-3 times.

**Habitat.** Puna grassland; usually rocky, occasionally with scattered bushes. At 2750–4800 m.  
**Food and Feeding.** Recorded dietary items include Coleoptera, Lepidoptera larvae, also small seeds. Forages singly or in pairs. Gleans arthropods from ground and from bases of bunch-grass.  
**Breeding.** Season presumed during austral spring-summer, at least in S of range; fledglings in Dec in N Peru and Mar in N Bolivia. Presumably monogamous. Nest a ball c. 12 × 15 cm, of grass, side entrance hole, lined with feathers, hair and plant material, placed on ground within clump of bunch-grass. No further information.  
**Movements.** Resident; some downslope movement reported during snowstorms in S.  
**Status and Conservation.** Not globally threatened. Fairly common to common throughout much of range. Tolerates at least moderate grazing.  
**Bibliography.** Bond (1945), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Koepeke (1954, 1970), Morrison (1939), O'Neill & Parker (1978), Parker *et al.* (1982), Pearman (1990), Remsen (2003a), Remsen & T aylor (1989), Ribero (1991), Ridgely & Tudor (1994), Stotz *et al.* (1996), Taczanowski (1884), Vuilleumier (1980a), Walker (2001), Whitney *et al.* (1994), Zimmer (1930, 1936a).

## 137. Streak-backed Canastero

### *Asthenes wyatti*

**French:** Synallaxe de Wyatt

**Spanish:** Canastero de Wyatt

**German:** Nördlicher Schwarzstrichelcanastero

**Taxonomy.** *Synallaxis wyatti* P. L. Slater and Salvin, 1871, Páramo de Pamplona, Santander, Colombia.

Considered by some to form a superspecies with *A. sclateri* and *A. anthoides*. Possibly best treated as conspecific with first of those, as birds in L Titicaca region (Peru-Bolivia border) appear to be intergrades between the two; S races (*azuay*, *graminicola*) formerly treated as a separate species, and they may indeed be more closely related to *A. sclateri* than to other taxa in present species. Species limits of both in need of careful revision. Race *mucochiesi* considered doubtfully distinct from nominate by some authors. Racial identity of birds reported in N Peru unknown; tentatively included within *azuay*. Seven subspecies tentatively recognized.

#### Subspecies and Distribution.

*A. w. sanctaemartae* Todd, 1950 - N Colombia (Santa Marta Mts).  
*A. w. perijana* Phelps, Jr., 1977 - Perijá Mts, on NE Colombia-NW Venezuela border.  
*A. w. mucochiesi* Phelps, Sr. & Gilliard, 1941 - Andes of W Venezuela (Trujillo, Mérida).  
*A. w. wyatti* (P. L. Slater & Salvin, 1871) - E Andes of N Colombia (N Santander).  
*A. w. aequatorialis* (Chapman, 1921) - W Andes of C Ecuador (Cotopaxi S to Chimborazo).  
*A. w. azuay* (Chapman, 1923) - Andes of S Ecuador (Azuay, Zamora-Chinchipec, N Loja) and N Peru (sight records from Piura, Cajamarca, Ancash).  
*A. w. graminicola* (P. L. Slater, 1874) - Andes of C & S Peru (Junin S to Puno).

**Descriptive notes.** 17 cm; 17–25 g. Rather dark canastero with streaked back. Nominative race has narrow buff supercilium, rest of face grizzled light brown and blackish, darkest on lores; crown to uppertail-coverts olive-brown with dense dark brown streaks, beginning as flecks on forehead, becoming fine streaks on crown and neck, broadening on back; wings dark fuscous, coverts with rufous margins, primaries with tawny-rufous margins, secondaries with rufous bases (forming wingband); tail graduated, central rectrices tapering to rounded tips, central three pairs dark fuscous brown with progressively more rufous on outer webs, outer three pairs mostly rufous with some dark fuscous along inner webs; chin tawny-buff, centre of upper throat light orange-rufous with narrow dark brown streaks, lower throat pale brownish-grey with narrow streaks continuing from upper throat; breast light brown with inconspicuous (often invisible) dark brown flecks and spots, belly bright tawny-buff, flanks and undertail-coverts rufescent buff; iris brown to dark brown; upper mandible black to dark horn, lower mandible greyish-horn to pinkish with black tip; tarsus and toes black to greyish. Sexes alike. Juvenile is darker brown throughout, lacks throat patch, has less distinct streaks on upperparts. Race *sanctaemartae* has broader but less contrasting streaks above (contrary to original description), darker orange throat, dingy greyish-buff underparts, longer bill; *mucochiesi* is very like nominate, but upperparts less brownish, edgings on crown and back greyer, other purported but disputed differences being shaft streaks on back darker (brownish-black), uppertail-coverts light olivaceous grey (rather than brown with buff-brown edges), outer rectrices with blackish edging on basal halves of inner webs; *perijana* is most like previous, but upperparts darker brown, underparts light brown (instead of smoky greyish), underside of tail dark chestnut-brown (instead of cinnamon-brown); *aequatorialis* is like nominate, but upperparts more grey-brown or rufous-brown, spots larger and blacker, tail blacker; *azuay* is more buffy below than previous, distinctive in having wings almost entirely rufous; *graminicola* is duller than last, underparts tawny with only hint of streaks. **VOICE.** Song of race *mucochiesi* described as of two types, either a single insect-like trill or 3 shorter insect-like trills, both lasting c. 1 second, of *aequatorialis* and *azuay* as accelerating fast trill c. 2 seconds long with slightly rising pitch, and for *graminicola* as trilled burst c. 1.5 seconds long; whether differences are real or are artifacts of different describers awaits formal analysis. Contact call described as “chick”, “tick” or “took” note, usually in series; also as doubled or tripled short trill (Ecuador).

**Habitat.** Páramo and puna grassland, often arid, usually with rocks and with or without low bushes; mainly in *Espeletia* mixed with shrubs and tussock grass in N parts of range. Mostly 3000–4500 m; locally to 5000 m and (*sanctaemartae*) down to 2400 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs. Mainly terrestrial. Gleans items from ground, grass clumps and *Espeletia* foliage; noted also as leaping into air to catch flying insects.

**Breeding.** Eggs in Jan in S Peru; fledgling in Apr in N Colombia. Presumably monogamous. Nest a round mass c. 25 cm in diameter, of dried leaves and grass stems, well interwoven, entrance hole on side opens directly into nest-chamber c. 12 cm in diameter, lined with fine grasses; placed near ground in clump of grass, extremely well concealed (unlike nests of most congeners). Clutch 2–3 eggs.

**Movements.** Resident; some downslope movement reported during snowstorms in S Andes.

**Status and Conservation.** Not globally threatened. Rare to locally common; rather scarce and local in Ecuador. Occurs in Sierra Nevada National Park, in Venezuela, Cotopaxi National Park, in Ecuador, and in Machu Picchu Historical Sanctuary, in Peru.

**Bibliography.** Chapman (1926), Cory & Hellmayr (1925), Dorst (1963), Fjeldså & Krabbe (1990), Hilty (2003a), Hilty & Brown (1983, 1986), Koepeke (1954, 1970), Krabbe (2000), Krabbe *et al.* (1996), Morrison (1939), O'Neill & Parker (1978), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Pearman (1990), Phelps (1977b),

Remsen (2003a), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stotz *et al.* (1996), Taczanowski (1884), Todd (1950b), Todd & Carriker (1922b), Vuilleumier (1980a, 1997), Vuilleumier & Ewert (1978), Walker (2001), Wetmore (1926).

## 138. Puna Canastero

### *Asthenes sclateri*

**French:** Synallaxe de Cordoba

**Spanish:** Canastero de la Puna

**German:** Südlicher Schwarzstrichelcanastero

**Other common names:** Cordoba Canastero; Puno Canastero (“*punensis* group”); Bolivian Canastero (*cuchacanchae*); Lillo’s Canastero (*lilloi*)

**Taxonomy.** *Synallaxis Sclateri* Cabanis, 1878, Sierra de Córdoba, Argentina.

Considered by some to form a superspecies with *A. wyatti* and *A. anthoides*. Possibly best treated as conspecific with former, as birds in L Titicaca region (Peru-Bolivia border) appear to be intergrades between the two; race *punensis* (with *cuchacanchae* and *lilloi*) previously considered conspecific with *A. wyatti*, and often treated as a separate species. Species limits in need of careful revision. Sight records from S Bolivia (Chiquisaca, Tarija) presumed referable to race *cuchacanchae*. Five subspecies recognized.

#### Subspecies and Distribution.

*A. s. punensis* (Berlepsch & Stolzmann, 1901) - Titicaca Basin in extreme S Peru (S Puno) and W Bolivia (La Paz).  
*A. s. cuchacanchae* (Chapman, 1921) - Andes of C Bolivia (Cochabamba, Potosí, sight records also from Chuquisaca and Tarija) and NW Argentina (Salta).  
*A. s. lilloi* (Oustalet, 1904) - Andes of NW Argentina (Catamarca, Tucumán, La Rioja).  
*A. s. sclateri* (Cabanis, 1878) - NC Argentina (Sierra de Córdoba and other mountains in region).  
*A. s. brunescens* Nores & Yzurieta, 1983 - C Argentina (Sierra de San Luis).

**Descriptive notes.** 17–18 cm; 19–27 g. Nominative race has buff supercilium, rest of face mottled greyish-brown; crown to uppertail-coverts pale grey-brown with blackish streaks margined with dull rufous; wing-coverts dark brown, strongly margined with rufous-chestnut, basal half of remiges bright rufous, rest brown with rufescent margins; tail graduated, central rectrices with rounded tips, central pair dark grey-brown, remainder dark fuscous with rufous tips, rufous increasing in extent towards outer rectrices; throat whitish with indistinct pale rufous patch in centre, underparts tawny-buff, paler on belly; iris brown; upper mandible dark grey, lower mandible light grey; tarsus and toes light brownish. Sexes alike. Juvenile is darker, with darker throat. Race *punensis* is darker and greyer above than nominate, much like race *graminicola* of *A. wyatti* but rectrices longer, broader and with rufous restricted to tips (also back paler and less heavily streaked), juvenile with mottled breast; *cuchacanchae* is paler and more heavily streaked above, wingband paler, paler and less tawny below, especially on flanks and undertail-coverts; *lilloi* is like previous, but upperparts slightly darker, tinged rufescent, and more heavily marked, wingband and primary coverts deeper rufous; *brunescens* differs from last in being greyer above, wing-coverts and wingband paler rufous, more whitish and less cinnamon below. **VOICE.** Song (nominative race) an accelerating and ascending trill 1–2 seconds long; call (nominative) described as soft “tzip” or “chup”. Voice evidently not unlike that of *A. wyatti*.

**Habitat.** Southern temperate grassland; rocky puna grassland, usually with tall bunch-grass and shrubs; locally in *Polylepis* woodland with bunch-grass as ground cover. Mainly 2000–4000 m; locally down to 1800 m.

**Food and Feeding.** Arthropods. Solitary or in pairs; gleans food items from ground and grass clumps.

**Breeding.** Season presumably during austral spring-summer; eggs in Sept-Jan and nestlings in Jan in Argentina. Presumably monogamous. Nest a domed mass c. 10 × 15 cm, of interwoven dried leaves and stems, sometimes with moss, lichens and dead leaves, side entrance c. 10 cm above ground level, extremely camouflaged, often incorporating living grass stems into structure, interior chamber c. 10 cm in diameter, sometimes also with long (25–35 cm) lateral entrance; placed close to ground in middle of or at base of grass clump. Clutch 2–3 eggs.

#### Movements.

**Status and Conservation.** Not globally threatened. Fairly common; not well known. Habitat generally subject to at least moderate grazing pressure.

**Bibliography.** Bond (1945), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Dorst (1963), Fjeldså & Krabbe (1990), Fjeldså & Majer (1996), Fraga & Narosky (1985), Hoy (1965, 1975), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1982), Nores, M. (1995), Nores, M. *et al.* (1983), Olrog (1962, 1963a), Parker *et al.* (1982), de la Peña (1987, 1988), Remsen (2003a), Remsen & T aylor (1989), Ridgely & Tudor (1994), Salvador (1990), Schulenberg & Awbrey (1997b), Stotz *et al.* (1996), Stresemann (1948), Vuilleumier (1980a, 1997).

## 139. Austral Canastero

### *Asthenes anthoides*

**French:** Synallaxe austral

**Spanish:** Canastero Austral

**German:** Südlicher Flügelspiegelcanastero

**Taxonomy.** *Synallaxis anthoides* P. P. King, 1831, no locality; type presumably from Strait of Magellan, Chile.

Considered by some to form a superspecies with *A. wyatti* and *A. sclateri*; “*punensis* group” of latter previously considered conspecific. Plumage similarities between present species and *A. hudsoni* have suggested to some authors that the two are sister-taxa. Monotypic.

**Distribution.** Breeds from S Chile (Andean foothill region from possibly Concepción S to Aisén, also from Magallanes) and SW Argentina (foothills in S Neuquén S to Chubut, and in Santa Cruz) S to Tierra del Fuego.

**Descriptive notes.** 16–17 cm; 21–23 g. Relatively short-tailed canastero with striped dorsal pattern like that of a pipit (*Anthus*). Has dull pale buff supercilium extending to forehead, dark fuscous lores and postocular area; rest of face brownish to grey-brown with faint streaking; crown and upperparts sandy brown with blackish streaks, these densest on crown, thinning on nape and upper back, becoming very broad on rest of back, narrowing again on rump and uppertail-coverts; wing-

coverts dark brown, greater edges tawny, medians and lessers with broad dull rufous margins, remiges dark fuscous with contrasting dull pale tawny bases of primaries, tawny-rufous bases of secondaries; tail graduated, central rectrices tapering to blunt points, central pair dark olive-brownish with sharply defined broad dark brownish stripe along length of shaft, next pair almost entirely dark fuscous, outer three pairs with increasing amounts of pale rufous at tips and tawny-whitish outer webs; chin whitish, centre of upper throat pale orange-rufous, rest of throat greyish-buff with fine indistinct dark greyish streaks; breast

browner and darker with narrow indistinct dark streaks, blending to lighter belly with only hint of streaks, centre almost whitish, flanks light warm brown with hint of streaks; iris brown to blackish; upper mandible black to dusky horn, lower mandible grey to dusky horn with pale base; tarsus and toes pinkish or dusky grey. Sexes alike. Juvenile lacks throat patch, has barring on breast. **VOICE.** Song a short, even trill lasting c. 1 second, reminiscent of that of *A. wyatti*; call described as "tick".

**Habitat.** Southern temperate grassland; mesic shrub-steppe dominated by *Chilothrichum diffusum* and *Berberis* shrubs 1-1.5 m tall and tussock grasses (especially *Festuca gracillima*); also locally in lower, more open scrub (e.g. dominated by *Mulinum spinosum* or *Lepidophyllum cupressiforme*) with little or no tussock grass, woodland dominated by *Nothofagus*, and beach scrub. Sea-level to 1500 m, occasionally to 1650 m.

**Food and Feeding.** Arthropods; recorded items are shield-bugs (Pentatomidae), and Coleoptera (of families Chrysomelidae, Carabidae, Tenebrionidae) and their larvae. Forages solitarily or in pairs. Gleans food items from ground and low vegetation, regularly leaping up to glean insects from grass stems; regularly "burrows" into grass clumps to forage.

**Breeding.** Season presumably during austral spring-summer; eggs in Dec and fledglings in Jan-Feb. Presumably monogamous. Nest a globular mass of thorny sticks, entrance hole on side but near top, no interior tunnel, interior lined with soft plant material, lichens and flowers. No further information.

**Movements.** Mostly resident; some populations possibly migratory, but evidence for this weak. Records N to Aconcagua (Chile) may refer to non-breeding migrants; reports from EC Argentina (Buenos Aires), Staten I (off Tierra del Fuego) and Falkland Is require verification.

**Status and Conservation.** Not globally threatened. Currently considered a species of Lower Risk/Least Concern. Uncommon to locally common. Although declines have been reported in recent decades, and it was suspected that this species was once characteristic of the Patagonian long-grass prairie (now destroyed by grazing), field studies have shown that it is not primarily a grassland species nor has it declined; rather, has become more common over the last century, at least in parts of Tierra del Fuego. On the other hand, habitat almost throughout range is subjected to degradation through intense, probably unsustainable levels of grazing.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Chesser (1994), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1925), Estes *et al.* (1994), Ejlsdå & Krabbe (1990), Grigera *et al.* (1996), Hellmayr (1932), Howell & Webb (1995c), Hoy (1975), Humphrey *et al.* (1970), Johnson (1967), Krabbe (2000), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bo (1982), Olrog (1948, 1962), Parker *et al.* (1982), Pässler (1922), de la Peña (1988), Philippi *et al.* (1954), Ralph (1985), Rasmussen *et al.* (1992), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1997), Wege & Long (1995), Woods (1988), Zotta (1932, 1936).

## 140. Hudson's Canastero

### *Asthenes hudsoni*

**French:** Synallaxe de Hudson

**Spanish:** Canastero Pampeano

**German:** Nördlicher Flügelspiegelcanastero

**Taxonomy.** *Synallaxis hudsoni* P. L. Selater, 1874, Conchitas, Buenos Aires, Argentina. Plumage similarities have suggested to some authors that this and *A. anthoides* are sister-species; others suggest that sister-taxon is *A. sclateri*. Monotypic.

**Distribution.** E Argentina (Santa Fe and Entre Ríos S to Rio Negro and S Buenos Aires), extreme SE Brazil (SE Rio Grande do Sul) and Uruguay.

**Descriptive notes.** 18 cm. Conspicuously streaked, long-billed canastero. Has narrow dull pale buff supercilium, rest of face sandy brownish; crown and upperparts sandy brown with prominent blackish and silvery streaks; wing-coverts dark brown, greater edges whitish-edged at tips, medians and lessers with broad dull rufous margins, remiges dark fuscous, contrasting whitish-tawny bases of primaries, tawny-rufous bases of secondaries; tail graduated, shafts stiffened basally, elongated central rectrices with very pointed tips, dusky with conspicuous silvery buff edgings; chin patch usually whitish, often tinged yellowish, occasionally orange-rufous (source of variation unknown); throat, breast and belly buff, becoming duller posteriorly, richer on sides and flanks to undertail-coverts, flanks with conspicuous blackish streaks; iris light brown; upper mandible fuscous black, lower mandible pale horn to grey with blackish tip; tarsus and toes drab light brownish. Sexes alike. Juvenile is distinctive, breast and sides with blackish-brown streaks. **VOICE.** Song a short ascending trill; call undescribed.

**Habitat.** Southern temperate grassland; tall wet grass (e.g. *Paspalum quadrifarium*) and sedges adjacent to wetlands; from near sea-level to 950 m.

**Food and Feeding.** Reported dietary items are Lepidoptera larvae, Coleoptera, shield-bugs (Pentatomidae), Orthoptera and Hymenoptera. Solitary or in pairs. Probably gleans arthropods from ground or low vegetation.

**Breeding.** Season during austral spring-summer; eggs in Nov-Dec and nestlings in Nov. Presumably monogamous. Nest extremely well concealed, a hollow scooped out on ground under clump of grass or thistles and with domed cover of fine grass and small twigs, or spherical mass of grass slightly above ground level in grass clump, lined with feathers, hair and small twigs. Clutch 3-4 eggs, sometimes 2 (possibly) or 5.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common. Restriction to regions with wetlands naturally limits its population size. Potentially vulnerable to drainage, pollution and other problems that affect birds of wetlands.

**Bibliography.** Belton (1984), Bencke (2001), Canevari *et al.* (1991), Chebez *et al.* (1999), Comparatore *et al.* (1996), Cory & Hellmayr (1925), Cuervo (1985), Fraga & Narosky (1985), Isach & Martínez (2001), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Norez *et al.* (1983), Olrog (1963a), de la Peña (1988), Pinto (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Vuilleumier (1997), Wetmore (1926), Zotta (1932, 1936, 1940).

## 141. Line-fronted Canastero

*Asthenes urubambensis***French:** Synallaxe inca **German:** Dunkelrückencanastero **Spanish:** Canastero del Urubamba**Taxonomy.** *Siptornis urubambensis* Chapman, 1919, Machu Picchu, 14,000 feet [c. 4270 m], Cuzco, Peru.Plumage similarities suggest closer relationship to *A. flammulata* and *A. virgata* or to *A. maculicauda* than to others in genus. Two subspecies recognized.**Subspecies and Distribution.***A. u. huallagae* (J. T. Zimmer, 1924) - Andes of C Peru (San Martín S to Pasco).*A. u. urubambensis* (Chapman, 1919) - Andes of S Peru (Cuzco, Puno) and W Bolivia (La Paz, Cochabamba).**Descriptive notes.** 17-18 cm; 16-20 g. A large and heavily striped canastero, with narrow and "spiny" tail reminiscent of that of *Schizoeaca*. Nominate race has conspicuous whitish supercilium broadening behind eye, extending anteriorly to forehead; rest of face light brownish with conspicuous, narrow dark brown streaks; forehead dark brown with sharply defined golden-brown stripes, these fading on paler, browner crown; hindneck and upperparts rich brown, collar of blurry light brown streaks, some of these fading into upper back, some broad pale shaft streaks on uppertail-coverts; wings rich brown, dark fuscous tips of remiges;tail graduated, rectrices narrow and extremely pointed, vanes narrowing from about half-way along to become nearly non-existent at tips, rich brown; chin pale tawny to dark rufous, upper throat tawny to orange-rufous (source of variation uncertain); lower throat light buff-brown with dark brown streaks, blending to paler breast with broad dark brown and pale buff streaks, these fading into pale dull buff belly that contrasts sharply with rich brown flanks and undertail-coverts with pale shaft streaks; iris brown; upper mandible black to grey-horn, lower mandible silver-grey to pinkish, often with darker tip; tarsus and toes olive to grey. Sexes alike. Juvenile undescribed. Race *huallagae* is slightly darker and redder above, dorsal streaking much more restricted, primarily on forehead and hindneck, with more conspicuous, extensive and whiter (less buffy) streaking below extending through flanks and belly. **VOICE.** Song an ascending trill; call a high "tseut".**Habitat.** *Páramo* grassland and timber-line ecotone with mossy scrub with *Gynoxis* and *Ribes* bushes, and *Polylepis* groves; 3050-4300 m.**Food and Feeding.** Arthropods. Forages singly or in pairs. More arboreal than congeners, hops along branches; also walks on ground in manner of a pipit (*Anthus*). Gleans items from moss, bark and foliage in low vegetation, and sometimes from mossy ground; has been seen to make short sally-strikes to underside of grass.**Breeding.** No information.**Movements.** Resident.**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA and Peruvian High Andes EBA. Rare to uncommon, locally fairly common; distribution patchy, and clearly limited in areal extent because of narrow elevational range. Populations almost certainly declining, especially in Bolivia, as a result of habitat degradation and loss caused by grazing, burning, and firewood-gathering in timber-line region; *Polylepis* regeneration also greatly hindered by these activities. Important population of this species recently discovered in Carrasco National Park, in Bolivia, which is evidently fairly well protected. Occurs also in Machu Picchu Historical Sanctuary, in Peru.**Bibliography.** Collar & Andrew (1988), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Kessler & Herzog (1998), Parker & O'Neill (1980), Parker *et al.* (1982), Remsen (1985, 2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1968), Walker (2001), Zimmer (1924, 1930).

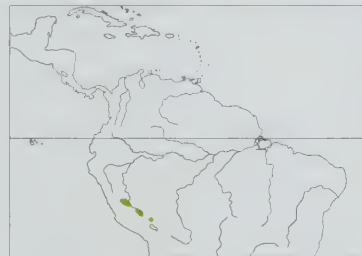

## 142. Many-striped Canastero

*Asthenes flammulata***French:** Synallaxe flammé **German:** Weißstrichelcanastero **Spanish:** Canastero Flamulado**Taxonomy.** *Synalaxis* [sic] *flammulatus* Jardine, 1850, "lofty table lands of the Andes" near Quito, 14,000 feet [c. 4270 m], Ecuador.Forms a superspecies with *A. virgata*, probably also including *A. maculicauda*. Possibly conspecific with former, which is its sister-species. Proposed race *pallida*, from N Peru, described as darker above with streaks whiter, paler below with reduced markings and more buffy flanks and undertail-coverts, is considered best synonymized with *taczanowskii*, although has been thought to be distinguishable by clearer back streaking and more of a buff-ochraceous wash on throat and neck. Four subspecies recognized.**Subspecies and Distribution.***A. f. multostriata* (P. L. Slater, 1858) - E Andes of Colombia (Norte de Santander S to S Cundinamarca).*A. f. quindiana* (Chapman, 1915) - C Andes of Colombia (Caldas S to Cauca).*A. f. flammulata* (Jardine, 1850) - W Andes of S Colombia (Nariño) S to extreme N Peru (N Cajamarca).*A. f. taczanowskii* (Berlepsch & Stolzmann, 1894) - Andes of N & C Peru (S Amazonas and S Cajamarca S to Ancash and Junín).**Descriptive notes.** 16-17 cm; 17-27 g. The most dramatically striped canastero. Nominate race has buff-whitish supercilium, rest of face dark brownish with buff to whitish flammulations; forehead bright tawny-brown or rufescent brown with dark brown stripes, these broadening and becoming the general colour of rest of crown, which has rufescent streaks; back to uppertail-coverts dark brown with conspicuous pale buff shaft streaks; wing-coverts dark brown with rufous margins,

remiges with reddish-rufous bases and dark fuscous tips; tail graduated, rectrices relatively narrow, especially distal halves, producing very "spiny" look, generally dark brown shafts and inner webs, rufous outer webs; chin and upper throat dull orange-buff to orange-rufous, blending to faintly flammulated and duller lower throat; breast and flanks whitish with conspicuous dark brown streaks, these becoming paler and less distinct on whitish belly; lower flanks and undertail-coverts rufescent brown with indistinct paler streaks; iris brown to dark brown; upper mandible black to dark horn, lower mandible black to dark brownish

with blue-grey to grey base; tarsus and toes light brown to olive to greenish-grey. Sexes alike. Juvenile has faint throat patch, less distinct streaks. Race *multostriata* is like nominate, but forehead darker chestnut, supercilium more ochraceous (not whitish), chin and throat deep rufous, ventral stripes with broader blackish margins, especially on flanks; *quindiana* differs from previous in having white chin, slightly paler throat, narrower ventral streaks; *taczanowskii* has throat pale buff to off white, ventral streaking restricted to upper breast and sides, extensive area in middle of breast nearly plain greyish-white (most individuals), also dorsal streaks narrower, forehead less tinged tawny. **VOICE.** Song in Colombia described as several whining notes followed by rattle; in Ecuador as fast, accelerating series of "tree" notes that usually end in trill, lasting c. 3 seconds; in N Peru as accelerating, buzzy "zhree-zree-ree-rrrr". Call a plaintive, mewing "peeow" or "tuuuuit"; also short "pyyt".**Habitat.** *Páramo* grassland in timber-line ecotone, usually with scattered bushes or *Espeletia* and rocks, often near woodland; mostly 3000-4500 m, locally down to 2800 m.**Food and Feeding.** Arthropods. Solitary or in pairs. Gleans items from ground or low vegetation, including from branches in bushes or low *Polylepis*.**Breeding.** No information.**Movements.** Resident.**Status and Conservation.** Not globally threatened. Uncommon to fairly common (mainly N races); not well known. Occurs in Cotopaxi National Park and Las Cajas National Recreation Area, in Ecuador. Suitable habitat generally limited in areal extent. Thought to be highly susceptible to overgrazing, but benefits from occasional burning of *páramo*.**Bibliography.** Bond (1945), Carriker (1933), Chapman (1926), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Koenen & Koenen (2000), Meyer de Schauensee (1945), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Peters & Griswold (1943), Remsen (2003a), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Vuilleumier (1968), Zimmer (1930).

## 143. Junin Canastero

*Asthenes virgata***French:** Synallaxe de Junin **German:** Braunschwanzcanastero **Spanish:** Canastero de Junín**Taxonomy.** *Synallaxis virgata* P. L. Slater, 1874, Junin, central Peru.Forms a superspecies with *A. flammulata*, probably also including *A. maculicauda*. Possibly conspecific with former, which is its sister-species. Monotypic.**Distribution.** Andes of C & S Peru (Lima, Junin, Ayacucho, Cuzco, Puno).**Descriptive notes.** 17-18 cm; 22 g. Has broad but rather "messy" greyish-white supercilium; rest of face a mix of dark brown and greyish feathers with varying amounts of pale shaft streaking; crown very dark brown with fine light rufous streaks; back dark brown with pale buff streaks, broader and more conspicuous than those on crown, rump brown with only hint of streaks, uppertail-coverts slightly darker with conspicuous buff-brown streaks; wings rich brown, coverts with darker margins and some dull rufous shaft streaks, remiges with dark fuscous tips; tail graduated, rectrices stiffened basally and very pointed, barbs virtuallyabsent at tips of central rectrices, producing "spiny" appearance, central two pairs dull brown, darker along shaft, rest of feathers with progressively increasing amounts of rufous; throat light orange-rufous, some paler shaft streaks at lower margin; breast whitish buff-grey with darker brown edges, these palest at breast centre and darkest at sides, giving rather mottled to scaled appearance; belly whitish buff-brown with some grey tones, faintly streaked darker brown, sides and flanks rich brown with broad pale buff-brown streaks, vent and undertail-coverts becoming more rufescent with vague streaking; iris brown to dark brown; upper mandible grey to horn, lower mandible pale grey to greyish-pink; tarsus and toes greenish-olive to olive. Sexes alike. Juvenile undescribed. **VOICE.** Song 2-3 notes followed by descending trilled series: "tree, tree, tree treeeeheehheehhe", evidently very similar to that of *A. flammulata*; calls described as mewing "tuuuuiit" and complaining "eek".**Habitat.** *Páramo* and *puna* grassland, in timber-line ecotone, with lush, tall bunch-grasses, usually mixed with low shrubs (e.g. *Lupinus*), often or, perhaps, usually near *Polylepis* woodland; 3250-4500 m.**Food and Feeding.** Little known. Solitary or in pairs; gleans arthropods from ground or low vegetation.**Breeding.** No information.**Movements.** Resident; some downslope movement during snowstorms reported.**Status and Conservation.** Not globally threatened. Restricted-range species: present in Peruvian High Andes EBA and Junin Puna EBA. Rare to uncommon; poorly known. Occurs in Machu Picchu Historical Sanctuary. Suitable habitat generally limited in areal extent. Thought to be highly susceptible to overgrazing and burning.

**Bibliography** Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Koepcke (1954), O'Neill & Parker (1978), Parker & O'Neill (1980), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1968), Walker (2001).

## 144. Scribble-tailed Canastero

### *Asthenes maculicauda*

**French:** Synallaxe à queue marbrée **German:** Roststirnecanastero **Spanish:** Canastero Estriado

**Taxonomy.** *Siptornis maculicauda* Berlepsch, 1901, Iquico, 4000 m, La Paz, Bolivia. Plumage pattern and biogeography indicate that this species is most closely related to *A. flammulata* and *A. virgata*; probably part of the superspecies formed by those. Disjunct population in Argentina may represent an undescribed race. Monotypic.

**Distribution.** Andes of S Peru (Puno), Bolivia (La Paz, Cochabamba, sight records also from Tarija) and NW Argentina (Sierra de Aconquija, in Tucumán and NC Catamarca).

**Descriptive notes.** 17 cm; 19 g. Large and conspicuously streaked canastero with unique tail pattern and lacking throat patch. Has buffy face with dark brown postocular stripe, some dark brown streaks on rear auriculars; rufous forehead blending to blackish-brown crown with conspicuous rufescent buff streaks, hindcrown dark brown with buff streaks; back and rump like hindercrown, streaks broader; wing-coverts dark brown with rufescent margins, remiges dark brownish fuscous with extensive rufous-chestnut bases; uppertail-coverts and central rectrices with distinctive pattern of ragged rufescent to buff-brown streaks matched by dark brown and

olive-brown streaks, rest of rectrices mostly dark fuscous with varying amounts of rufescent and olive-brown margins and streaks; throat pale greyish-buff, breast somewhat washed tawny, lower breast with band of blurry dark brown streaks, fading into belly, which is light buff-brownish; sides and flanks a mix of dark brown and light buff streaks, undertail-coverts light tawny-brown with vague darker streaks; iris brown; upper mandible grey to dark grey, lower mandible pale whitish-grey to grey, sometimes with darker tip; tarsus and toes olive to olive-green. Sexes alike. Juvenile has duller forehead, more mottled underparts, less distinct tail pattern. **Voice.** Song described as a series of "tree" notes that end in fast, descending trill; call a rising whistled "tuuiiii" or "tooeee".

**Habitat.** *Páramo* grassland; timber-line grassland with lush, tall bunch-grasses, often mixed with low shrubs; mostly 3000–4300 m, locally down to 2250 m.

**Food and Feeding.** Arthropods. Little known. Solitary or in pairs; probably gleans items from ground or low vegetation; noted sallying up into air to catch flying insects.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Rare to uncommon. Suitable habitat generally limited in areal extent, and greatly reduced by human use of fire in timber-line habitat. Thought to be highly susceptible to overgrazing and burning.

**Bibliography.** Bond (1945), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Kessler & Herzog (1998), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parker *et al.* (1982), de la Peña (1988), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vuilleumier (1968).

## 145. Sharp-billed Canastero

### *Asthenes pyrrholeuca*

**French:** Synallaxe vannier **German:** Dünnschnabelcanastero **Spanish:** Canastero Coludo  
**Other common names:** Lesser Canastero

**Taxonomy.** *Sylvia pyrrholeuca* Vieillot, 1817, Paraguay.

No obvious close relatives within genus; *A. haeri* suggested by some authors as possible sister-species on basis of plumage similarities. Proposed Argentine races *leptastheniroides* (of which *affinis* is a synonym), described from Tucumán, and *flavogularis*, from Bahía Blanca (Buenos Aires) and Santa Cruz, represent seasonal plumage variation within race *sordida* and nominate, respectively. Two subspecies recognized.

**Subspecies and Distribution.**

*A. p. sordida* (Lesson, 1839) - breeds C & S Chile (Aconcagua S to Aisén, also sight records from Magallanes) and WC Argentina (S Mendoza, Neuquén, W Río Negro); some migrate N to NW Argentina and S Bolivia.

*A. p. pyrrholeuca* (Vieillot, 1817) - breeds C & S Argentina (SW Santiago del Estero, NE Córdoba, and from S La Pampa and SW Buenos Aires S to C Santa Cruz; some migrate N to E & NE Argentina and S Paraguay.

**Descriptive notes.** 14–15 cm; 12–14 g. Rather typical canastero without distinctive features, but bill relatively thin and pointed. Has rather plain grey-brown face, indistinct paler supercilium; crown dull brown, back and rump slightly paler, rather long uppertail-coverts slightly browner; wings mostly dull rufescent brown; tail graduated, central rectrices tapering to fairly pointed tips, central three feather pairs mostly dark fuscous brown, becoming darker towards tips, outer three pairs mostly dull rufous with dark inner webs; chin and upper throat variable, rufous to tawny, partly occluded by pale buff shaft streaks with dark

tips; lower throat and breast pale dull greyish-brown with ill-defined and very faint streaks on breast; belly pale dull buff-brown, flanks and undertail-coverts darker and tinged rufescent; iris brown; upper mandible slate-grey to black, lower mandible grey-horn; tarsus and toes slate-grey. Sexes alike. Juvenile lacks throat patch, has mottled breast. Race *sordida* has outer rectrices entirely rufous. **Voice.** Song a 2-note trill, "tsee-ee-ee-ee, tsee-ee-ee-ee", repeated at 1-second intervals; contact call a rising "sweep", given at intervals of c. 0.5–1 seconds.

**Habitat.** Arid montane scrub, arid lowland scrub, southern temperate grassland; dense arid scrub, shrub-steppe, hilly and rocky grassland, and even sand dunes with scattered low bushes; in non-breeding range also in tall grass, marshy areas dominated by *Polygonum lapathifolium*, and Chaco scrub. Mostly sea-level to 2000 m, locally to 3000 m.

**Food and Feeding.** Recorded dietary items are Hemiptera (Membracidae) and Coleoptera (Carabidae, Chrysomelidae). Forages solitarily or in pairs, and often in mixed-species flocks. Evidently gleans arthropods primarily from low vegetation, and thus is less terrestrial in its feeding than are most congeners.

**Breeding.** Season during austral spring-summer; eggs in Sept-Dec, nestlings in Nov and fledglings in Feb; possibly double-brooded. Presumably monogamous. Nest an interwoven spherical to globular mass c. 20–30 cm in diameter, made of small twigs, some as long as 15 cm, entrance near top or on side, interior chamber c. 6 × 13 cm, lined with soft plant material, hair and feathers, placed 0.4–1 m up in crotch of branches in bush; also, two nests reported slightly underground, one c. 30 cm under flat rock and with almost no nesting material, the other made of hair and sited at end of rodent burrow c. 30 cm long. Clutch 2–4 eggs.

**Movements.** Partly resident; an unknown proportion of population migrates N during austral winter, reaching S Bolivia (*sordida*) and S Paraguay (nominate). Some post-breeding downslope movement of uncertain extent in N & W of range.

**Status and Conservation.** Not globally threatened. Fairly common to abundant in most of range. Habitat typically subjected to at least moderate grazing pressure.

**Bibliography.** Anon. (2003d), Araya & Chester (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Chesser (1994), Contreras (1979b), Cory & Hellmayr (1925), Cuello (1985), Fjeldså & Krabbe (1990), Fraga & Narosky (1985), Grigera *et al.* (1996), Hayes (1995), Howell & Webb (1995c), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky (1971), Narosky *et al.* (1983), Nores & Yzurieta (1975), Nores *et al.* (1983), Olrog (1958, 1962, 1963a), Pearman (1990, 1994e), de la Peña (1987, 1988), Pereyra (1951), Rasmussen *et al.* (1992), Remsen & Traylor (1989), Ridgely & Tudor (1994), Salvador (1988, 1990), Smyth (1928), Stotz *et al.* (1996), Vuilleumier (1993a), Vuilleumier, Capparella & Lazo (1992), Wetmore (1926), Zotta (1936).

## 146. Dusky-tailed Canastero

### *Asthenes humicola*

**French:** Synallaxe à queue noire **German:** Rostschultercanastero **Spanish:** Canastero Colinegro

**Taxonomy.** *Synallaxis* [sic] *humicola* Kittlitz, 1830, near Valparaíso, Chile.

Plumage similarities and biogeography suggest that sister-species is *A. patagonica*. Three subspecies recognized.

**Subspecies and Distribution.**

*A. h. goodalli* Marin *et al.*, 1989 - N Chile (SW Antofagasta).

*A. h. humicola* (Kittlitz, 1830) - NC Chile (Atacama S to N Maule); old record from W Argentina (N Mendoza) requires confirmation.

*A. h. polysticta* Hellmayr, 1925 - SC Chile (S Maule, Concepción, Arauco, Malleco).

**Descriptive notes.** 14–15 cm; 18–24 g. One of the darkest and dullest of all canasteros. Nominate race has narrow supercilium and supraloral spots whitish, rest of face dark grey-brown with inconspicuous paler streaks; crown dark brown, faintly flammulated, back slightly paler, rump and uppertail-coverts faintly tinged dull rufescent; wings dull brown like back, except for dull rufous shoulder area; tail graduated, central rectrices slightly pointed, colour like back but becoming dark fuscous toward tips, rest of rectrices fuscous blackish, increasingly slightly paler on outer webs; throat whitish, with blackish flecking

increasing in density towards upper breast, where becomes short streaks; rest of breast brownish-grey with faint pale streaking, belly paler with virtually no hint of streaks, flanks rufescent brown, undertail-coverts darker rufous-brown; iris brown; upper mandible black, lower mandible grey with black tip; tarsus and toes greenish. Sexes alike. Juvenile has streaking on underparts even fainter than adult. Race *goodalli* has more slender bill, less pronounced breast streaks, more streaks on face, darker crown, brighter cinnamon on shoulder, flanks and undertail-coverts; *polysticta* is like nominate, but flanks and undertail-coverts duller brown, ventral spotting more extensive. **Voice.** Song described as a loud clear trill; birds also give a ticking "ts-ts-ts-ts-ts-ts".

**Habitat.** Arid montane scrub, arid lowland scrub; dense *matorral* scrub, and semi-arid hillside scrub dominated by *Acacia cavenia*; from near sea-level to 1200 m.

**Food and Feeding.** Little known. Solitary or in pairs. Apparently gleans arthropods from low foliage or ground; usually within 1 m of ground.

**Breeding.** Reported to have two broods per year, one in Aug, a second in Nov; eggs in Jan in Argentina. Presumably monogamous. Nest a conspicuous elongated, vertical or upward-angled cylinder c. 25–35 cm long, made of twigs, usually thorny ones, external entrance tube with hole at side near top, inner chamber c. 8 cm in diameter and with pad of plant material and feathers, placed in low bush. Clutch 3–4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Central Chile EBA. Uncommon to fairly common. In most of range its habitat is subject to at least moderate grazing and other disturbance. Occurs in several protected areas, e.g. Cerro La Campana National Park, in Chile.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Johnson (1967), Marin *et al.* (1989), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), de la Peña (1987, 1988), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore (1926).

## 147. Creamy-breasted Canastero

### *Asthenes dorbignyi*

**French:** Synallaxe d'Orbigny **German:** Rostbüzelcanastero **Spanish:** Canastero Rojizo  
**Other common names:** Black-winged Spinetail; Pale-tailed Canastero (*huancavelicae*); White-tailed Canastero (*usheri*)

**Taxonomy.** *Bathmidura Dorbignyi* Reichenbach, 1853, Palca, Cochabamba, Bolivia.

Forms a species group, and possibly a superspecies, with *A. herlepsi*, also including probably *A. steinbachi* and *A. baeri* and possibly *A. patagonica*. May be conspecific with first of those, and considered by some to be conspecific with second of them. In some aspects of plumage, tail structure, behaviour, voice and nest structure, all are more similar to *Phacellodomus* (especially *P. striaticeps*) and possibly better placed in that genus. Races *huancavelicae* and *usherii*, with distinctive vocal differences from others, sometimes treated as one or two separate species. Brown-backed, paler-faced populations from Chile and W Bolivia are probably intergrades between *arequipae* and either *consobrina* or nominate. In addition, two highly distinctive populations in C Peru (Ancash, Lima, Huánuco and Ayacucho) represent undescribed races or possibly separate species. Present taxonomic treatment traditional but considered unsatisfactory; formal revision required. Five subspecies recognized.

**Subspecies and Distribution**

*A. d. huancavelicae* Morrison, 1938 - Andes of W & SC Peru (locally in Ancash, also Huancavelica and Ayacucho).  
*A. d. usherii* Morrison, 1947 - Andes of SC Peru (Aurimac).  
*A. d. arequipae* (P. L. Selater & Salvin, 1869) - Andes of SW Peru (Arequipa S to Taena and S Puno), N Chile (Tarapacá) and W Bolivia (SW La Paz, NW Oruro).  
*A. d. consobrina* Hellmayr, 1925 - Andes of SW Bolivia (SE La Paz, NE Oruro, N Potosí).  
*A. d. dorbignyi* (Reichenbach, 1853) - Andes of C & S Bolivia (Cochabamba S to E Potosí and Tarija) and NW Argentina (Jujuy S to Mendoza).

blackish, some rufous margins on outer pairs; centre of throat orange-rufous with some black feather bases; rest of throat, breast and belly dull creamy or creamy whitish, brightest on belly (some individuals evidently retain some faint barring of juvenile plumage on breast); flanks tawny-rufous, undertail-coverts rufous; iris brown to light grey; upper mandible black to dark grey, lower mandible blackish, usually with grey or pinkish base; tarsus and toes dull blue-grey to black. Sexes alike. Juvenile lacks throat patch, has faint mottling on breast and belly. Race *consobrina* is like nominate, but blacker remiges nearly lack rufous bases (no conspicuous wingband), back slightly darker, darker rufous on wing-coverts, rump, outer webs of rectrices, flanks and undertail-coverts; *arequipae* is larger, with deeper bill, darker above (especially crown), blacker lores and auriculars, lacks rufous wingband, has larger, more conspicuous throat patch, more extensive rufous in outer rectrices; *usherii* is paler, brown above without rufous on rump, pale greyish below with faint scaling on breast, has whitish-buff outer rectrices; *huancavelicae* is superficially like nominate in being rather small and smaller-billed, but duller and slightly darker above, less rufous in wings, darker face, paler throat patch, whitish-buff to pale rufous outer webs of outer rectrices. **VOICE.** Song (nominate race) c. 2-3-5 seconds long, a series of high notes, first ascending and accelerating, then descending and slowing, sometimes ending in explosive trill, sometimes introduced by various additional slower series of notes and trills; gives antiphonal duet; contact call a rising, penetrating "shreep!" or "wheel" at c. 2-5-second intervals. Race *arequipae* song lacks introductory notes, is shorter (c. 3 seconds), described as descending series of rattling, ringing notes, often quavering; alarm call described as a series of descending notes, "kee, kee, kî, kee, kee". Songs of *huancavelicae* and *usherii* reported as high-pitched, intense trills lasting c. 2 seconds, thus very different from other taxa.

**Habitat.** Arid montane scrub; a variety of arid scrubby habitats, often with columnar cacti, especially in gorges and on steep slopes, in hilly or mountainous terrain; also in or near *Polylepis* woodland (*arequipae*). Sometimes found in vicinity of human settlements. At 1800-4800 m; nominate race down to 700 m in non-breeding season.

**Food and Feeding.** Recorded dietary items are ants and seeds. Forages singly or in pairs. Evidently gleans arthropods mainly from ground, also from low vegetation.

**Breeding.** Season presumably during austral spring-summer; eggs in Nov-Dec in Peru and in Nov and Feb in Argentina; fledglings in Jan-Feb in Bolivia. Presumably monogamous. Nest a large cylindrical mass, highly variable in size (25-400 cm long, diameter 23-60 cm), of usually thorny sticks woven together, tapering towards external entrance tube at top, spherical inner chamber 6-10 cm in diameter, lined all the way around with feathers, hairs and plant down (possibly only in colder areas) or with pad of plant material, hair and feathers; placed in bush, small tree, or thorny plant such as columnar cactus (e.g. *Pseudoespostoa*, *Cylindropuntia*) or *Puya raimondii*. One clutch documented, of 2 eggs.

**Movements.** Mainly resident; some post-breeding downslope movement in Argentina.  
**Status and Conservation.** Not globally threatened. Races *huancavelicae* and *usherii* Vulnerable. Fairly common to common in much of range. Tolerates moderate habitat degradation, including severe overgrazing, and found in vicinity of houses and agriculture. In C Peru, the undescribed taxa (both apparently rare) may also merit the conservation status of Vulnerable; the combined total population of those, along with *huancavelicae* and *usherii*, is estimated at 2500-10,000 individuals, and declining as a result of habitat destruction and degradation. One of the undescribed taxa occurs in Huascarán National Park, in Ancash. Surveys needed in order to locate all forms and to assess their ecological and conservation requirements, as well as to determine their taxonomic status.

**Bibliography.** Araya & Chester (1993), Begazo *et al.* (2001), Canevari *et al.* (1991), Chebez *et al.* (1999), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Contreras (1980a), Cory & Hellmayr (1925), Dorr (1957), Fjeldså (1987), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Fraga & Narosky (1985), Hoy (1980), Johnson (1967), Krabbe *et al.* (1996), Mazar Barnett & Pearman (2001), Morrison (1938, 1939, 1947, 1948), Narosky *et al.* (1983), Navas & Bó (1987), Olrog (1963a), Pacheco *et al.* (1996a), Parker *et al.* (1982), Pearman (1990), de la Peña (1987, 1988), Remsen (2003a), Remsen & Traylor (1989), Ribero (1991), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Torres-Mura (1998), Traylor (1950), Wege & Long (1995), Wetmore (1926).

148. Berlepsch's Canastero

*Asthenes berlepschi*

**French:** Synallaxe de Berlepsch **Spanish:** Canastero de Berlepsch  
**German:** Cordillera Real-Canastero

**Taxonomy.** *Siptornis berlepschi* Hellmayr, 1917, Chilcani, La Paz, Bolivia.  
Forms a species group, and possibly a superspecies, with *A. dorbignyi*, probably also with *A. steinbachi* and *A. baeri* and possibly with *A. patagonica*; may be conspecific with *A. dorbignyi*, with treatment as species based more on historical momentum than on taxonomic analysis. In some aspects of plumage, tail structure, behaviour, voice and nest structure, all are more similar to *Phacellodomus* (especially *P. striaticeps*) and possibly better placed in that genus. Monotypic.  
**Distribution.** Consata Valley, in Andes of NW Bolivia (NC La Paz).

**Descriptive notes.** 15-16 cm. Has inconspicuous greyish supercilium, blackish lores and auriculars; crown warm brown, becoming paler and duller on back, rufous rump and uppertail-coverts; wings blackish, coverts edged and tipped dark rufous, tertials thinly edged dark rufous; tail graduated, rectrices very slightly pointed, outer two pairs rufous, next pair partly rufous, rest blackish; throat and underparts creamy whitish, centre of throat with hint of rufous (barely evident), breast with faint dark scaling, flanks and undertail-coverts rufous; bare-part colours not well known, but probably iris brown, upper mandible dark, lower mandible mainly grey, tarsus and toes blue-grey. Distinguished from very similar race *arequipae* of *A. dorbignyi* by lack of throat patch, broader rufous edges of wing-coverts and tertials, more rufous on outer rectrices. Sexes alike. Juvenile has dark-tipped breast feathers producing scaly appearance. **VOICE.** Song a trill similar to that of *A. dorbignyi*.

**Habitat.** Semi-arid montane scrub (*Baccharis pentlandii*) and patches of vegetation around human habitations, pastures and farms; recently reported also from degraded *Polylepis* woodland, and from scattered stands of introduced eucalyptus (*Eucalyptus*). At 2300-3700 m.

**Food and Feeding.** Little known. Solitary or in pairs; evidently gleans arthropods from ground and perhaps low vegetation.

**Breeding.** Season probably during austral spring-summer. Nest placed in tree. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Not well known; appears to be common, but recorded from only a few localities within tiny range. Observations cover area of c. 200 km<sup>2</sup>; possibly present elsewhere. N of R Consata, but fieldwork needed to determine this. In a 1991 survey, 3-4 nests found c. 500 m apart in area of eucalyptus trees separating agricultural fields. Tolerates strong habitat degradation; persists locally in absence of native vegetation, and has probably done so for thousands of years (back to at least Incan times). Nevertheless, its extremely small range places it at some risk.

**Bibliography.** Collar *et al.* (1992), Cory & Hellmayr (1925), Fjeldså & Krabbe (1989, 1990), Herzog *et al.* (1997), Lowen & Kennedy (1999), Maijer (1995), Mazar Barnett & Kirvan (2002c), Mazar Barnett *et al.* (1997), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

149. Steinbach's Canastero

*Asthenes steinbachi*

**French:** Synallaxe marron **German:** Weißkinncanastero **Spanish:** Canastero Castaño  
**Other common names:** Chestnut Canastero

**Taxonomy.** *Siptornis steinbachi* Hartert, 1909, Cachi, 2500 m, Salta, Argentina.  
Plumage pattern and biogeography suggest that this is part of the group, or possibly superspecies, formed by *A. dorbignyi* and *A. berlepschi*, also including probably *A. baeri* and possibly *A. patagonica*; considered by some authors to be a race of *A. dorbignyi*. In some aspects of plumage, tail structure, behaviour, voice and nest structure, all are more similar to *Phacellodomus* (especially *P. striaticeps*) and possibly better placed in that genus. Some, however, have predicted a closer relationship to *A. humicola*. Race *neiffi* of *A. baeri* originally described as a race of present species. Monotypic.

**Distribution.** Andes of W Argentina, from W Salta S to Mendoza.

**Descriptive notes.** 15-16 cm; 14-20 g. Rather greyish canastero lacking streaks and throat patch. Has mostly greyish-brown face, paler supercilium; crown and back dull grey-brown, greyest on nape, blending to chestnut rump and rufous-chestnut uppertail-coverts; wings mostly rufous, distal halves of remiges dark fuscous; tail graduated, central rectrices gradually tapering to slightly pointed tips, outer feathers rufous, rest blackish fuscous with rufescent margins on outer webs; chin and throat whitish with faint dusky tips, breast and belly greyish, flanks and undertail-coverts tawny-rufous; iris brown to dark brown; bill black to dark brown; tarsus and toes brown to black. Sexes alike. Juvenile undescribed. **VOICE.** Not described.

**Habitat.** Arid montane scrub, often in ravines, and *monte* woodland; 500-3000 m.

**Food and Feeding.** Little known. Solitary or in pairs; presumably gleans arthropods from ground or low vegetation.

**Breeding.** Season presumably during austral spring-summer; eggs in Nov and Jan. Presumably monogamous. Nest is a globular mass c. 34 cm tall and 28 cm wide, made of sticks, mostly thorny ones, entrance on upper side leads to interior nest chamber lined with grasses, soft plant matter, and feathers; 2-5 m up in bush. Clutch 2-3 eggs.

**Movements.** Mainly resident; some post-breeding downslope movement.

**Status and Conservation.** Not globally threatened. Currently considered a species of Lower Risk/Least Concern. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Rare to uncommon. In some parts of range, scrub habitat has been altered by human settlement and conversion to agriculture; grazing by domestic livestock possibly also a threat locally. On other hand, large areas of habitat throughout range remain in suitable condition.

**Bibliography.** Anon. (2003), Canevari *et al.* (1991), Chebez *et al.* (1999), Collar *et al.* (1994), Contreras (1979f, 1980a), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Olrog (1962, 1963a), de la Peña (1988), Ridgely & Tudor (1994), Salvador (1990, 1992), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore (1926).

## 150. Short-billed Canastero

*Asthenes baeri*

French: Synallaxe à bec court German: Kurzschnabelcanastero Spanish: Canastero Chaqueño

**Taxonomy.** *Siptornis baeri* Berlepsch, 1906, Cosquín, Córdoba, Argentina.Suggested by some authors as being possibly sister-species to *A. pyrrholeuca* on basis of plumage similarities. Others point out that voice, nest structure, plumage and tail morphology all indicate that it is part of a group, or possibly superspecies, formed by *A. dorbignyi* and *A. berlepschi*, probably with *A. steinbachi* and possibly with *A. patagonica*; in some aspects of plumage, tail structure, behaviour, voice and nest structure, all are more similar to *Phacellodomus* (especially *P. striaticeps*) and possibly better placed in that genus. Races *chacoensis* and *neiffi* (latter originally described as a race of *A. steinbachi*) perhaps no more than extremes in clinal variation, and species possibly monotypic; re-evaluation of geographical variation desirable. Three subspecies tentatively recognized.**Subspecies and Distribution.***A. b. chacoensis* Brodkorb, 1938 - extreme SC Bolivia (SC Santa Cruz) and NW Paraguay.*A. b. baeri* (Berlepsch, 1906) - S Bolivia (E Tarija), W Paraguay, N & C Argentina (Salta, W Formosa and W Corrientes S to E Mendoza, La Pampa, NE Rio Negro and S Buenos Aires), extreme SE Brazil (SW Rio Grande do Sul) and W Uruguay.*A. b. neiffi* (Contreras, 1980) - W Argentina (NW & C Mendoza, W Córdoba, N & C San Luis).**Descriptive notes.** 14-15 cm; 10-18 g. Rather pale, plain, short-billed canastero, in many ways more similar in plumage to sympatric *Phacellodomus sibilatrix* than to congeners. N nominate race has indistinct broad greyish supercilium, rest of face dull greyish-brown; crown dull grey-brown, back slightly greyer, rump and uppertail-coverts tinged brown; wings mostly dull greyish-brown, coverts and remiges with paler grey edgings; tail graduated, central rectrices relatively narrow, tips slightly pointed, inner two pairs mostly dark brownish fuscous, rest mostly dull rufous; chin pale greyish; upper throat orange-tawny, becoming darker along lower margin, where some dark feather bases show; lower throat and rest of underparts pale dull greyish, flanks and undertail-coverts pale rufescent; iris brown to greyish-brown; upper mandible black to dark grey or dark brown, lower mandible grey to pinkish-grey; tarsus and toes grey to brownish-grey. Sexes alike. Juvenile lacks or has less distinct throat patch, has mottled upper breast. Race *chacoensis* is very slightly paler than nominate, with whiter supercilium, more extensively rufous tail; *neiffi* is apparently significantly larger than other races.

VOICE. Song a few introductory notes followed by long, fast trill of mechanical, dry notes; terminal trill frequently given without introductory notes. Also series of short, buzzing "pzzz" phrases.

**Habitat.** Arid lowland scrub; Chaco scrub and woodland, and *monte* woodland; from sea-level up to 1300 m.**Food and Feeding.** Recorded items include ants, Orthoptera (including Acrididae), Diptera, Coleoptera (including Cerambycidae), Hymenoptera, Dermaptera. Forages singly or in pairs. Apparently gleans arthropods from branches and twigs of low vegetation, occasionally from ground.**Breeding.** Season during austral spring-summer; eggs in Oct-Jan and nestlings in Oct. Presumably monogamous. Nest an oval mass c. 24-35 × 15-20 cm, usually taller than wide, made of spiny branches, entrance hole at top, curving tunnel leading to interior chamber of c. 10 cm diameter, floor a bed of feathers, hair, twigs, occasionally also flowers, moss or lichens; placed 1-5-3 m up in fork of branches in bush or low tree. Clutch 3 eggs, sometimes 4, but 5 recorded in Argentina (Mendoza); incubation period 14-15-5 days; nestling period 14 days.**Movements.** Resident.**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Occurs in several protected areas. Habitat occupied by this species is subject to at least moderate disturbance and grazing in large parts of its range.**Bibliography.** Anon. (2003d), Belton (1984), Cabot (1990), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1980a), Cory & Hellmayr (1925), Cuello (1985), Fraga & Narosky (1985), Guerrero & Arambiza (2001), Hoya *et al.* (1995), Kratter *et al.* (1993), Mazar Barnett & Pearman (2001), Mezquida (2001b), Narosky *et al.* (1983), Nares *et al.* (1983), Ochoa (1971), Pacheco *et al.* (1996a), Partridge (1953), de la Peña (1987, 1988, 1995), Pinto (1978), Remsen (2003a), Remsen & T aylor (1983, 1989), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Wetmore (1926), Zotta (1940).

## 151. Cipo Canastero

*Asthenes luizae*

French: Synallaxe du Cipo German: Minas Gerais-Canastero Spanish: Canastero de Cipo

**Taxonomy.** *Asthenes luizae* Viellard, 1990, Alto da Boa Vista, 1100 m, near Jaboticatubas, Serra do Cipó, Minas Gerais, Brazil.Relationships uncertain; plumage most similar to that of *A. patagonica*, but voice most similar to that of *A. dorbignyi*. Monotypic.**Distribution.** EC & NC Minas Gerais, in SE Brazil.**Descriptive notes.** 17 cm; 25-5-30-5 g. Rather short-billed canastero with medium-length tail. Has narrow whitish supercilium, dark brown or blackish-brown eyeline, rest of face grey-brown with fine blackish streaks, some narrow whitish streaks on auriculars; crown warm brown, back and rump greyish-brown; wings dull dark brown, outer five primaries with dull whitish-brown narrow edges on basal half forming pale panel, primary coverts dark fuscous; tail graduated, central rectrices tapering somewhat at tip, remainder with rounded tips, central pair dark brown, rest chestnut-rufous; chin and centre of upper throat white with fine black streaks; throat side and underparts grey, slight dusky olive wash on belly centre, deeper on rear flanks, more chestnut on undertail-coverts; in worn plumage looks duller, more evenly greyer overall, with colder and less markedbrown tones; iris blackish to brown; upper mandible dark grey with black tip, lower mandible similar or with paler grey base; tarsus and toes dull pinkish or grey. Sexes alike. Juvenile undescribed. **VOICE.** Song a series of usually 11 descending notes, fades towards end, lasts c. 3 seconds; contact call a high-pitched, metallic "jlip", repeated at 2-second intervals.**Habitat.** *Campo rupestre*: rocky outcrops with bushy vegetation in grassland; 900-1500 m.**Food and Feeding.** Arthropods. Forages singly or in pairs; gleans items from ground or rocks.**Breeding.** Presumably breeds during austral spring-summer; dependent young observed in Dec. Territory estimated at 100-300 m<sup>2</sup>. No further information.**Movements.** Resident.**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in Central Brazilian Hills and Tablelands EBA. Discovered as recently as 1985, and not formally described until 1990. Currently known from six localities in Minas Gerais, including Serra do Cipó National Park (where found in 1997) and Pico do Itambé State Park. Fairly common in Serra do Intendente (Ribeirão do Campo waterfalls), and not uncommon at type locality (a little NE of Jaboticatubas); six individuals recorded in 1-5 km in Pico do Itambé. Total population estimated at 2500-10,000 individuals in late 1990s; thought to be declining, mainly as a result of habitat destruction and degradation. Considered to be at risk because of tiny geographical range and insular nature of habitat; grazing and burning of habitat potential threats. Possible brood parasitism by Shiny Cowbird (*Molothrus bonariensis*), apparently a recent invader of the region, not hitherto recorded for this species but could have serious effects (other *Asthenes* canasteros are occasional hosts for this cowbird). On the other hand, discovery of this species in Mar 2000 at Campina do Bananal, 170 km N of other known localities and N of Jequitinhonha Valley, gives cause for optimism. Additional fieldwork in region, where much suitable habitat still exists, may reveal that it is more widespread than hitherto known, and may lead to its threat category being downgraded.**Bibliography.** de Andrade *et al.* (1998), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cordeiro *et al.* (1998), Ferreira de Vasconcelos & Sá (2002), Ferreira de Vasconcelos *et al.* (2002), Machado *et al.* (1998), Melo-Júnior *et al.* (2001), Pearman (1990), Ridgely & Tudor (1994), Sick (1993, 1997), da Silva (1995a), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Studer & Teixeira (1993), Viellard (1990b), Vuilleumier, LeCroy & Mayr (1992).

## 152. Patagonian Canastero

*Asthenes patagonica*

French: Synallaxe de Patagonie German: Fleckenkehlcanastero Spanish: Canastero Patagón

**Taxonomy.** *Synallaxis patagonica* d'Orbigny, 1839, Rio Negro, Patagonia, Argentina.Plumage similarities and biogeography have suggested to some authors that sister-species is *A. humicola*. Voice, tail structure, nest structure, foraging behaviour and habitat, however, indicate that it may be more closely related to the group, possibly a superspecies, formed by *A. dorbignyi* and *A. berlepschi* and also including probably *A. steinbachi* and *A. baeri*; in some aspects of plumage, tail structure, behaviour, voice and nest structure, all of these are more similar to *Phacellodomus* (especially *P. striaticeps*) and possibly better placed in that genus. Monotypic.**Distribution.** S Argentina, from S Mendoza, La Pampa and S Buenos Aires S to N Santa Cruz.**Descriptive notes.** 14-15 cm; 14-19 g. Relatively small, plain and dull canastero. Has light greyish-brown, almost plain face, hint of paler supercilium and darker postocular line; crown and upperparts light grey-brown, wings somewhat browner with more rufescent edgings; tail graduated, central rectrices slightly pointed, dull grey-brown at base, otherwise mostly blackish; chin and throat greyish-white, blackish flecking and streaking on throat; breast dull pale greyish, blending to pale buff-grey upper belly, tawny flanks and lower belly, dull tawny-rufous undertail-coverts; bare-part colours not documented, probably dark. Sexes alike. Juvenile undescribed.**VOICE.** Song a loud, penetrating trill on single pitch, "tree-ee-ee-ee-ee-ee...", lasts c. 4 seconds, occasionally duets; call a single loud, sharp note, often repeated.**Habitat.** Arid lowland scrub; semi-arid scrub (e.g. *Atriplex*, *Condalia microphylla*, *Schinus*) on flats, slopes or washes; from near sea-level to 700 m.**Food and Feeding.** Little known. Arthropods, including Coleoptera, Hymenoptera, Diptera, spiders; also seeds. Evidently usually solitary; appears to glean arthropods from ground under bushes or from low vegetation.**Breeding.** Season during austral spring-summer; eggs in Oct-Dec and nestlings in Oct-Nov. Presumably monogamous. Nest a spherical mass c. 40-50 cm long, 20-30 cm wide, of thorny sticks, some as long as 30 cm, external tubular side entrance 15-40 cm long, interior chamber 12-15 cm in diameter, with pad of soft plant material, hair and feathers, placed 1-6 m above ground in bush. Clutch 3 eggs, sometimes 4.**Movements.** Resident.**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Habitat in much of its range subjected to at least moderate grazing.**Bibliography.** Anon. (2003d), Canevari *et al.* (1991), Cawell & Hamilton (1961), Chebez *et al.* (1999), Contreras (1980e), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fraga & Narosky (1985), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bö (1986, 1987), Nares *et al.* (1983), Olrog (1963a), Pacheco *et al.* (1996a), Pearman (1990), de la Peña (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1993a), Wetmore (1926).

PLATE 23

inches 3  
cm 8

# Genus *PHACELLODOMUS* Reichenbach, 1853

## 153. Rufous-fronted Thornbird

### *Phacellodomus rufifrons*

**French:** Synallaxe à front roux **German:** Rotstirn-Bündelnister **Spanish:** Espinero Común  
**Other common names:** Common/Plain Thornbird, Plain-fronted/Red-fronted Thornbird; Northern Thornbird (*inornatus*, *castilloi*); Marañon/Peruvian Thornbird (*peruvianus*)

**Taxonomy.** *Anabates rufifrons* Wied, 1821, Riberão de Ressaca, Bahia-Minas Gerais border, Brazil. Considered by some authors to form a superspecies with *P. sibilatrix*, but the two overlap considerably in distribution, and differ in body size and nest structure. N races *inornatus* and *castilloi* sometimes treated as constituting a separate species; *peruvianus* possibly also a separate species. Proposed race *fargoi*, from Paraguay and S Brazil (Mato Grosso), described as browner above and with flanks and undertail-coverts more fulvous, but found to be not diagnosable by these characters; treated as synonym of *sincipitalis*. Six subspecies recognized.

#### Subspecies and Distribution.

*P. r. inornatus* Ridgway, 1887 - NC Venezuela (SE Falcón, Yaracuy and Carabobo E to Miranda).  
*P. r. castilloi* Phelps, Jr. & Avelado, 1987 - W & C Venezuela (Lara, Portuguesa, Barinas and Apure E to Sucre and Monagas) and NE Colombia (Boyacá, Arauca, Casanare, Vichada, NE Meta).  
*P. r. peruvianus* Hellmayr, 1925 - extreme S Ecuador (S Zamora-Chinchipe) and N Peru (upper Marañón Valley in Amazonas, Cajamarca and San Martín).  
*P. r. sincipitalis* Cabanis, 1883 - E Bolivia (Beni, Santa Cruz, Tarija), S Brazil (S Mato Grosso), NC Paraguay and NW Argentina (Jujuy, Salta, Tucumán).  
*P. r. specularis* Hellmayr, 1925 - NE Brazil (Pernambuco).  
*P. r. rufifrons* (Wied, 1821) - E Brazil (S Maranhão, S Piauí, Bahia, N Minas Gerais).

**Descriptive notes.** 16-17 cm; 18-31 g. Rather plain, nondescript, arboreal furnariid. Nominate race has dull buff supercilium continuing anteriorly to supraloral area, dark greyish lores, dark brown postocular area; rest of face light buff-brown; forehead dark rufous, crown dark brownish with some paler shaft streaks, back to uppertail-coverts dull brown, slightly paler than crown; wing-coverts and remiges dull brown, darker brown primary coverts; tail graduated, dull brown; fairly uniform brownish-white below, darker brownish at sides, richer brownish on flanks, rufescent-tinged undertail-coverts; iris brown to grey to greyish-white (source of variation uncertain, possibly age-related); upper mandible blackish to dark grey, lower mandible grey to blue-grey; tarsus and toes grey. Sexes alike. Juvenile lacks rufous on forehead, upperparts mottled. Race *sincipitalis* is like nominate, but back slightly brighter brown, rump, uppertail-coverts and flanks slightly brighter, more rufescent, outer rectrices slightly more rufous; *peruvianus* has rufous of forehead more extensive and slightly paler, flanks brighter and more extensively fulvous; *specularis* is distinctive in having rufous patch in remiges, also more brownish above than nominate, deeper and more extensive rufous on crown, rufescent outer rectrices; *inornatus* lacks rufous on forecrown, is the plainest race; *castilloi* is like previous, but back and wing-coverts more olivaceous, less rufescent, face more greyish (less brownish), tail, thighs and undertail-coverts more brownish. Voice. Song a loud, strained series of shrill "chit" notes, slowly accelerating and intensifying, then slowing and ending abruptly, length variable, up to 10 seconds, often as antiphonal duet; repeated frequently, and often given from near or inside nest. Often long bouts of twittering, weak notes that may continue for several minutes. Alarm a sharp "chip" or "chek".

**Habitat.** Arid lowland scrub, tropical deciduous forest, *cerrado*, arid montane scrub, secondary forest, gallery woodland, *llanos*, savanna, and open scrub with scattered trees; locally in open semi-humid woodland; key habitat components seem to be dense thickets and at least some scattered trees for nesting. Mostly from near sea-level to 1300 m, locally to 2000 m.

**Food and Feeding.** Reported dietary items are Coleoptera (including families Curculionidae, Carabidae), Orthoptera (including Acrididae), Hemiptera, ants, and spiders. Usually in pairs, or in groups of 3-10 individuals, including nest helpers; rarely in mixed-species flocks. Forages mostly on ground, occasionally up to mid-storey. Gleans arthropods primarily from leaf litter, usually under bushes and herbaceous growth; sometimes "blurs" into dense litter, but evidently does not use flaking or tossing manoeuvres. Occasionally glean items from dead leaves and branch surfaces in trees and bushes.

**Breeding.** In Venezuela season mostly Jul-Nov, eggs in Apr-Jul and nestlings in May-Sept, at least two broods per year; in S of range during austral spring-summer, eggs in Oct-Dec and Mar in Argentina; laying in Sept and Dec in E Brazil, often two broods. Presumably monogamous; territory and pair-bond maintained throughout year. Up to 5 (occasionally 8) young from previous broods may remain with parents, and help with building, maintenance and defence of subsequent nests. Nest enormous in relation to bird's size, a cylinder c. 0.5-2.5 m long, 25-100 cm wide, made of sticks, often thorny ones, some as long as 52 cm, tunnels 10-15 cm long, often bending, connect entrance holes (usually all on same side of nest) to two or more (as many as 8-9) separate chambers 10-15 cm in diameter, often with smaller antechambers, lined with bits of bark, leaves, hair, reptile skin and feathers, eggs placed in lowest chamber; suspended 2-23 m above ground from end of branch (which often droops or partially breaks under weight of nest), usually in isolated small tree or cluster of trees, new nest often placed near previous one; old nests regularly reused. Clutch 3-4 eggs; incubation by both sexes, period 16-17 days; both sexes feed chicks, one observation of a helper delivering food, nestling period 21-22 days. Nest often usurped by other bird species, especially Troupial (*Icterus icterus*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to fairly common in most parts of range. Occurs in numerous protected areas. Tolerates at least moderate anthropogenic habitat disturbance.

**Bibliography.** Alves & Cavalcanti (1996), Arvey (1964), Canevari *et al.* (1991), Capper, Clay *et al.* (2001), Carrara & Rodrigues (2001), Chebez *et al.* (1999), Coelho *et al.* (1997), Cory & Hellmayr (1925), Davis (1993), Fiora

## 154. Little Thornbird

### *Phacellodomus sibilatrix*

**French:** Synallaxe siffleur **German:** Zwergbündelnister **Spanish:** Espinero Chico  
**Other common names:** Doering's Thornbird

**Taxonomy.** *Phacellodomus sibilatrix* P. L. Sclater, 1879, no locality = presumably Córdoba, Argentina.

Considered by some authors to form a superspecies with *P. rufifrons*, but the two overlap considerably in distribution, and differ in body size and nest structure. Monotypic.

**Distribution.** Extreme S Bolivia (SW Santa Cruz), W Paraguay, N Argentina (S to E La Rioja, N San Luis, C Córdoba and N Buenos Aires) and SW Uruguay.

**Descriptive notes.** 13-14 cm; 14-16 g. The smallest *Phacellodomus*. Has broad dull buff-whitish supercilium extending anteriorly to supraloral area, vague narrow dull brown postocular line; rest of face dull light brownish; forehead light rufous with paler shaft streaking, blending to dull brown crown and back; rump and uppertail-coverts faintly tinged rufescent; rufous lesser wing-coverts, dull brown median and great coverts, dark brown primary coverts, faintly rufescent-tinged remiges with darker tips; tail graduated, central two pairs of rectrices dull brown like back, next pair mainly rufous with distal third brownish, outer two pairs bright rufous; throat and belly dingy whitish, blending to slightly darker breast; flanks and undertail-coverts tinged tawny-brown; iris greenish-grey to dark brown (source of variation uncertain); upper mandible black to dark grey, lower mandible light grey-horn to grey; tarsus and toes grey to pinkish-grey. Differs from *P. rufifrons* mainly in smaller size, paler plumage. Sexes alike. Juvenile has slightly darker upperparts, slightly grayer underparts. Voice. Song variable, described as a series of shrill, well-spaced "cheep" notes, slightly descending, decelerating; also duet in which presumed male gives well-spaced "chet" notes, presumed female higher-pitched trilled rattle; lasts c. 6 seconds. Call a sharp "chip", often repeated.

**Habitat.** Tropical deciduous forest, Chaco woodland and scrub; from near sea-level to 2000 m.

**Food and Feeding.** Recorded dietary items are Coleoptera, spiders, Orthoptera, Formicidae. Observed in pairs or in small groups (possibly nest helpers), occasionally in mixed-species flocks. Gleans arthropods from ground or low vegetation, up to mid-storey.

**Breeding.** Season during austral spring-summer; eggs in Sept-Feb and nestlings in Oct in Argentina. Presumably monogamous. Nest a cone-shaped mass c. 25-40 cm tall, c. 40-45 cm wide at base, made of sticks, usually thorny ones, some up to 25 cm long, horizontal tunnel c. 35 cm long connects side entrance hole at lower end (entrance hole once at top of nest) to interior chamber 9-15 cm in diameter, often with smaller antechamber, lined with bits of plant cotton, leaves, hair, moss, lichens, snake skin, spider web and feathers, often additional, smaller chambers (rarely as many as three) often connected to each other but not to main nest-chamber; suspended 1-5 m above ground from end of drooping branch (weight of nest sometimes makes branch droop), usually in isolated small tree or cluster of trees, sometimes on top of older nest. Clutch 3 eggs, sometimes 4. Nest often usurped by other bird species.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to uncommon in much of its range. Occurs in Chancani Natural Reserve, in Argentina.

**Bibliography.** Anon. (2003d), Brooks (1997), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Guerrero & Arambiza (2001), Hayes (1995), Kratter *et al.* (1993), Mason (1985), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Nores *et al.* (1983), Olrog (1963a), Pacheco *et al.* (1996a), Parker, Gentry *et al.* (1993), Pearman (1994d), de la Peña (1987, 1988, 1995), Remsen (2003a), Ridgely & Tudor (1994), Stotz *et al.* (1996), Wetmore (1926).

**155. Streak-fronted Thornbird**

### *Phacellodomus striaticeps*

**French:** Synallaxe à front rayé **German:** Strichelstirn-Bündelnister **Spanish:** Espinero Andino  
**Other common names:** Red-shouldered Thornbird

**Taxonomy.** *Anumbius striaticeps* d'Orbigny and Lafresnaye, 1838, Sicasica, La Paz, Bolivia.

Uncanny resemblance in plumage to *Asthenes dorbignyi* presumed due to convergence. Description of darker Peruvian race *griseipectus* (type locality in Cuzco) is matched by specimens from near city of La Paz, in Bolivia (not far from type locality of nominate); in addition, populations from Puno evidently differ from those in Apurimac and Cuzco. Further study, particularly examination of the types, is warranted. Two subspecies tentatively recognized.

#### Subspecies and Distribution.

*P. s. griseipectus* Chapman, 1919 - dry Andean valleys of S Peru (Apurimac, Cuzco, Puno).  
*P. s. striaticeps* (d'Orbigny & Lafresnaye, 1838) - Andes of Bolivia (S from La Paz) and N Argentina (S to Catamarca and Tucumán).

**Descriptive notes.** 16-17 cm; 23-29 g. Nominate race has indistinct dull grey-buff supercilium, supraloral area tinged rufous, lores blackish mixed with grey-buff, indistinct dark brown postocular line; rest of face brownish with light rufous wash; forehead mixed blackish and reddish with brown

On following pages: 156. Freckle-breasted Thornbird (*Phacellodomus striatocollis*); 157. Chestnut-backed Thornbird (*Phacellodomus dorsalis*); 158. Greater Thornbird (*Phacellodomus ruber*); 159. Red-eyed Thornbird (*Phacellodomus erythrophthalmus*); 160. Canebrake Groundcreeper (*Clibanornis dendrocolaptoideus*); 161. Firewood-gatherer (*Anumbius annumbi*); 162. Lark-like Brushrunner (*Coryphistera alaudina*); 163. Spectacled Prickletail (*Siptornis striatocollis*); 164. Orange-fronted Plushcrown (*Metopothrix aurantiaca*).

shaft streaks, blending to paler and browner hindcrown without streaks; back and uppertail-coverts rich dark brown, rump slightly paler; wings mostly dark brown, median and lesser coverts rufescent, primary coverts fuscous brown, margins of remiges tinged rufescent basally and with dusky tips; tail graduated, central pair of rectrices dark brown, then increasing amounts of chestnut-rufous basally until outer pair all chestnut-rufous; throat and belly dull buff-white, light grey-brown extending from side of breast almost to centre, flanks and undertail-coverts light rufescent buff; iris dark brown to grey (source of variation uncertain); upper mandible dusky horn to dark grey, lower mandible pale horn to pale blue-grey, often with dusky tip; tarsus and toes greenish-grey to blue-grey. Differs from *P. rufifrons* in much heavier build, darker plumage; remarkably similar to syntopic races of *Asthenes dorbignyi*. Sexes alike. Juvenile undescribed. Race *griseipectus* described as darker above, with greyer breast, darker rufous flanks, no rufous wash on face. VOICE. Song a long accelerating and descending series of strained, complaining "cheet" notes interspersed with ticking "tsidit" notes, often given as duet. Call an irregular series of squeaky "jit" or "tsip" notes; also a loud trill.

**Habitat.** Arid montane scrub, often with columnar cacti or (locally) *Puya raimondii*, and *Polylepis* woodland; locally, ranges into agricultural fields and areas around houses. At 2800-5000 m; down to 1200 m in non-breeding season.

**Food and Feeding.** Reported dietary items include Lepidoptera larvae. Usually observed in pairs, from ground up to canopy. Gleans and probes for arthropods on branches, clumps of moss and epiphytic vegetation, and ground.

**Breeding.** Season during austral summer; eggs in Dec and fledgling in Mar in S Bolivia; eggs in Dec-Mar and nestlings in Feb in Argentina. Presumably monogamous. Nest a bulky cylindrical mass 60-150 cm high, 30-50 cm wide, of thorny branches, lateral entrance hole leads to interior chamber 8-11 cm in diameter, lined with deep layer of shredded plant material, hair and feathers; often conspicuously placed in bush or low tree, often overhanging ravine or cliff, occasionally on crossbar of telephone pole. Clutch 3-4 eggs, occasionally 5.

**Movements.** Mainly resident; some post-breeding downslope movements by S populations.

**Status and Conservation.** Not globally threatened. Uncommon to common, especially in S portion of range. Tolerates at least modest anthropogenic habitat disturbance, including fairly severe grazing; sometimes found near and around human habitations, suggesting reasonable adaptability. **Bibliography.** Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Dorst (1957), Fjeldsá & Krabbe (1990), Fjeldsá & Majer (1996), Fraga & Narosky (1985), Krabbe *et al.* (1996), Lönnberg (1903), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parker *et al.* (1982), de la Peña (1987, 1988, 2001a), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ribero (1991), Ridgely & Tudor (1994), Schmitt *et al.* (1997), Smyth (1928), Stotz *et al.* (1996).

## 156. Freckle-breasted Thornbird

### *Phacellodomus striaticollis*

**French:** Synallaxe rousselé

**German:** Fleckenbrust-Bündelnister

**Spanish:** Espinero Pechimoteado

**Other common names:** Rufous-headed Thornbird; Spot-breasted Thornbird (*maculipectus*)

**Taxonomy.** *Anumbius striaticollis* d'Orbigny and Lafresnaye, 1838, Buenos Aires, Argentina. Distinctive race *maculipectus* often treated, with some justification, as a separate species, differing from nominate in plumage, iris colour, voice, habitat and nest shape. Isolated population in forest fragments in Catamarca and La Rioja (NW Argentina), differing in having dark chestnut forehead concolorous with rest of crown, and darker, more olivaceous back, represents an undescribed race. Two subspecies recognized.

#### Subspecies and Distribution.

*P. s. maculipectus* Cabanis, 1883 - Andes from C Bolivia (Cochabamba) S to NW Argentina (S to La Rioja).

*P. s. striaticollis* (d'Orbigny & Lafresnaye, 1838) - NE Argentina (E Formosa S to E Córdoba and N Buenos Aires), SE Brazil (S from E Paraná) and Uruguay.

shaft streaks and irregular, indistinct dark rufous "freckles", belly dull light brownish-white, flanks and undertail-coverts dull grey-brown; iris yellow to creamy buff or pale orange; upper mandible blackish to brownish, lower mandible grey, sometimes with dark tip; tarsus and toes grey to greenish-grey. Sexes alike. Juvenile has less rufescent back. Race *maculipectus* has grey eyes, more rufous (less brownish-chestnut) crown with whitish shaft streaks, more conspicuous supercilium, darker underparts, especially breast, with more conspicuous whitish speckles. VOICE. Song starts with one to several ascending low notes, sometimes hesitating, followed by 3-4 loud, shrill descending monotonic notes that end abruptly, "psep, psep, psep-kleek, kleek, kleek"; *maculipectus* song described as similar but stronger, faster, longer, lower-pitched, 10-25 less evenly spaced, complaining notes, "kew, kéé-keee-keee-keee-keee-keee...", lasts 2.5-3 seconds, or up to 10 seconds when given as duet. Alarm a series of squeaky ticking notes.

**Habitat.** Nominative race inhabits riparian thickets, gallery forest, arid lowland scrub, and marsh borders, almost always near water; near sea-level to 700 m. Race *maculipectus* in dry to semi-humid montane woodland (e.g. *Alnus acuminata*, *Podocarpus*) and scrub (e.g. *Baccharis. Miconia*); mostly 1000-2500 m, locally to 3100 m.

**Food and Feeding.** Recorded food items of nominate race are Coleoptera (of families Curculionidae, Elateridae, Chrysomelidae, Tenebrionidae), shield-bugs (Pentatomidae), squash-bugs (Coreidae), grasshoppers (Acrididae), and Diptera; Coleoptera and their larvae recorded for *maculipectus*.

shaft streaks, blending to paler and browner hindcrown without streaks; back and uppertail-coverts rich dark brown, rump slightly paler; wings mostly dark brown, median and lesser coverts rufescent, primary coverts fuscous brown, margins of remiges tinged rufescent basally and with dusky tips; tail graduated, central pair of rectrices dark brown, then increasing amounts of chestnut-rufous basally until outer pair all chestnut-rufous; throat and belly dull buff-white, light grey-brown extending from side of breast almost to centre, flanks and undertail-coverts light rufescent buff; iris dark brown to grey (source of variation uncertain); upper mandible dusky horn to dark grey, lower mandible pale horn to pale blue-grey, often with dusky tip; tarsus and toes greenish-grey to blue-grey. Differs from *P. rufifrons* in much heavier build, darker plumage; remarkably similar to syntopic races of *Asthenes dorbignyi*. Sexes alike. Juvenile undescribed. Race *griseipectus* described as darker above, with greyer breast, darker rufous flanks, no rufous wash on face. VOICE. Song a long accelerating and descending series of strained, complaining "cheet" notes interspersed with ticking "tsidit" notes, often given as duet. Call an irregular series of squeaky "jit" or "tsip" notes; also a loud trill.

**Habitat.** Arid montane scrub, often with columnar cacti or (locally) *Puya raimondii*, and *Polylepis* woodland; locally, ranges into agricultural fields and areas around houses. At 2800-5000 m; down to 1200 m in non-breeding season.

**Food and Feeding.** Reported dietary items include Lepidoptera larvae. Usually observed in pairs, from ground up to canopy. Gleans and probes for arthropods on branches, clumps of moss and epiphytic vegetation, and ground.

**Breeding.** Season during austral summer; eggs in Dec and fledgling in Mar in S Bolivia; eggs in Dec-Mar and nestlings in Feb in Argentina. Presumably monogamous. Nest a bulky cylindrical mass 60-150 cm high, 30-50 cm wide, of thorny branches, lateral entrance hole leads to interior chamber 8-11 cm in diameter, lined with deep layer of shredded plant material, hair and feathers; often conspicuously placed in bush or low tree, often overhanging ravine or cliff, occasionally on crossbar of telephone pole. Clutch 3-4 eggs, occasionally 5.

**Movements.** Mainly resident; some post-breeding downslope movements by S populations.

**Status and Conservation.** Not globally threatened. Uncommon to common, especially in S portion of range. Tolerates at least modest anthropogenic habitat disturbance, including fairly severe grazing; sometimes found near and around human habitations, suggesting reasonable adaptability. **Bibliography.** Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Dorst (1957), Fjeldsá & Krabbe (1990), Fjeldsá & Majer (1996), Fraga & Narosky (1985), Krabbe *et al.* (1996), Lönnberg (1903), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olrog (1963a), Parker *et al.* (1982), de la Peña (1987, 1988, 2001a), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ribero (1991), Ridgely & Tudor (1994), Schmitt *et al.* (1997), Smyth (1928), Stotz *et al.* (1996).

Usually in pairs, foraging from ground to understorey. Gleans arthropods from ground and from vegetation (including emergent marsh vegetation for nominate).

**Breeding.** Season during austral spring-summer; eggs in Aug-Jan and nestlings from Sept to early Feb in E (nominate); eggs in Oct-Nov in W (*maculipectus*). Monogamous. Nest (nominate race) an oblong, globular mass c. 30-50 cm long, 25-30 cm high, 12-20 cm wide, of sticks, usually thorny ones, side entrance on upper end leads through curving tunnel to antechamber, then to nest-chamber c. 10-12 cm in diameter, lined with soft plant material (such as inflorescences of *Typha*), sometimes the portion containing antechamber elaborated into second element, giving nest the form of two joined spheres, placed 1-3 m up, often above water or marsh vegetation, supported by branches in small tree; *maculipectus* a cylindrical or triangular mass (c. 30 × 30 × 20 cm) of twigs, often spiny, side or bottom entrance leading to two chambers, one above the other, nest itself in upper chamber, c. 10 cm in diameter, chamber and tunnel lined with fine grasses; suspended 3-4 m up from end of branch. Clutch 3-4 eggs, sometimes 2 or 5 (nominate), or 3 eggs (*maculipectus*, few data); incubation period c. 16 days; nestling period c. 12-13 days. Nests regularly parasitized by Shiny Cowbird (*Molothrus bonariensis*) and Striped Cuckoo (*Tapera naevia*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Present in several protected areas, e.g. Esteros del Iberá National Park, Ingeniero Otamendi Nature Reserve and Costanera Sur Ecological Reserve, in Argentina.

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Fjeldsá & Majer (1996), Krabbe *et al.* (1996), Mason (1985), Mazar Barnett & Pearman (2001), Mazar Barnett, Clark *et al.* (1998), Narosky *et al.* (1983), Nores & Cerana (1990), Nores & Yzurieta (1981), Nores *et al.* (1983), Olrog (1956, 1963a), de la Peña (1987, 1988, 1995), Pinto (1978), Remsen & Traylor (1989), Ridgely & Tudor (1994), Salvador (1988, 1992), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Todd & Carriker (1922a), Wetmore (1926), Whitney *et al.* (1994), Willis (1992b), Zotta (1936).

## 157. Chestnut-backed Thornbird

### *Phacellodomus dorsalis*

**French:** Synallaxe à dos marron

**German:** Graunacken-Bündelnister

**Spanish:** Espinero Dorsicastaño

**Taxonomy.** *Phacellodomus* [sic] *dorsalis* Salvin, 1895, Malca, 8000 feet [c. 2440 m], near Cajabamba, Cajamarca, Peru.

**Monotypic.**

**Distribution.** NW Peru (upper Marañón Valley in S Cajamarca and La Libertad); reports from Ancash require documentation.

chestnut with dull fuscous tips; tail graduated, central pair of rectrices mostly dull chestnut with browner inner webs, rest rufous-chestnut, some dull brown on tips; throat and malar area white; upper breast tawny brownish with whitish shaft spots, forming irregular breastband, rufous at breast side continuing to and broadening on flanks; lower breast and belly vaguely mottled whitish and brownish, some rufous flecking along flanks; undertail-coverts rufescent brownish, vaguely mottled; iris grey; upper mandible dark olive-horn to dark horn, lower mandible silver-grey to olive-grey; tarsus and toes grey to blue-grey. Juvenile undescribed. VOICE. A series of ticking "chit-chit-chit-chit-chit" notes given for long periods and varying in intensity, either alone or accelerating and breaking into a loud, even loudsong "chup-chup-chupchupchuppppp" accelerating at the end.

**Habitat.** Arid montane scrub, on brushy slopes with scattered short *Prosopis* trees; 1800-2800 m. **Food and Feeding.** Little known. Observed singly or in pairs, usually 1-4 m from ground; evidently gleans arthropods from branches and, possibly, from foliage.

**Breeding.** Season not documented. Presumably monogamous. Nest a large cylinder of twigs and branches, placed near tip of branch (perhaps mostly in *Prosopis*). No further information.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Marañón Valley EBA. Uncommon; reported as fairly common around Hacienda Limón, in Cajamarca. Known from only 5-6 localities within its small range (less than 2000 km²). Population estimated at fewer than 10,000 individuals; declining as a result of destruction of habitat, much of which already lost to cultivation. Tolerates at least modest habitat degradation (overgrazing, cutting for firewood). Main threats to habitat appear to be cattle-ranching and the continued planting of oil palms (*Elaeis guineensis*).

**Bibliography.** Begazo *et al.* (2001), Cory & Hellmayr (1925), Dinerstein *et al.* (1995), Fjeldsá & Krabbe (1990), Parker *et al.* (1982), Remsen (2003a), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## 158. Greater Thornbird

### *Phacellodomus ruber*

**French:** Synallaxe rouge

**German:** Rotbrauner Bündelnister

**Spanish:** Espinero Grande

**Other common names:** Yellow-eyed Thornbird

**Taxonomy.** *Furnarius ruber* Vieillot, 1817, Paraguay.

**Monotypic.**

**Distribution.** NC & E Bolivia (La Paz, Beni, E Santa Cruz), interior S Brazil (S Mato Grosso and Mato Grosso do Sul E to W Bahia, S to NW São Paulo and NW Paraná, also W Rio Grande do Sul), Paraguay and N Argentina (Salta and Formosa S to Tucumán, Santa Fe, Entre Ríos and Corrientes).

**Descriptive notes.** 19-21 cm; 35-51 g. Bulkier and redder thornbird. Has face mostly rufescent brown to greyish-brown, slightly paler in supercilium and supraloral areas; crown reddish-chest-

nut with faint pale shaft streaks, hindcrown and back rich reddish-brown to olive-brown (much individual variation), sometimes becoming more chestnut on lower back, rump lighter rufescent brown, uppertail-coverts chestnut; wings relatively uniform, rufous-chestnut; tail graduated, reddish-chestnut; throat and malar area whitish, blending to pale breast tinged with light brownish, darkening at side; belly whitish, flanks and undertail-coverts light rufescent brown; iris light yellow to orange-yellow to orange; upper mandible blackish to dark greyish-horn, lower mandible pale grey to greyish-green; tarsus and toes grey to olive.

Sexes alike. Juvenile lacks well-defined crown patch, has breast mottled brownish. VOICE. Song described as a long series of 15-20 "chip" notes that start explosively, then slowly accelerate and fade; duets. Call sharp "check check" and "chweet".

**Habitat.** Riparian thickets, gallery woodland and scrub, almost always near water; occasionally ventures into emergent marsh vegetation when foraging. Mostly 300-1100 m; locally to 1400 m in Bolivia.

**Food and Feeding.** Recorded food items include ants and Coleoptera. Usually seen in pairs, mostly in understorey; also, regularly terrestrial. Evidently gleans arthropods from dense vegetation and from ground.

**Breeding.** Season during austral spring-summer; eggs in Oct-Jan. Nest a cone-shaped mass c. 35-60 cm tall, 30-50 cm in diameter at base, made of twigs and branches, often thorny ones, some branches as long as 50-60 cm, side entrance at lower end leads to interior chamber (sometimes with antechamber) c. 10-12 cm in diameter, lined with fine grasses and feathers; suspended 1-4-3 m up from low vegetation, often over water, occasionally placed on top of old nest. Clutch 3-4 eggs, rarely 5.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to common throughout range. Occurs in a number of protected areas, including Pantanal National Park, in Brazil, and Esteros del Iberá and Calilegua National Parks, in Argentina.

**Bibliography.** Anon. (2003d), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1979d), Cory & Hellmayr (1925), Davis (1993), Friedmann (1927), Guerrero & Arambiza (2001), Hayes (1995), Ihering (1914), Marini, Motta-Júnior *et al.* (1997), Mazar Barnett & Pearman (2001), Naumburg (1930), Narosky *et al.* (1983), Navas & Bö (1988), Parker *et al.* (1991), de la Peña (1987, 1988, 1995), Perry *et al.* (1997), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Straube & Bornschein (1995), Wetmore (1926).

## 159. Red-eyed Thornbird

### *Phacellodomus erythrophthalmus*

**French:** Synallaxe aux yeux rouges

**Spanish:** Espinero Ojirrojo

**German:** Orangebrust-Bündelnister

**Taxonomy.** *Anabates erythrophthalmus* Wied, 1821, Rio Catolé, Bahia, Brazil.

Formerly placed in a monotypic genus *Driocistis*. Distinctive: differs from congeners in terms of plumage and voice. Race *ferrugineigula* almost certainly a separate species; very recently reported as co-occurring with nominate in São Paulo. Two subspecies currently recognized.

**Subspecies and Distribution.**

*P. e. erythrophthalmus* (Wied, 1821) - SE Brazil, from S Bahia S to NE São Paulo.

*P. e. ferrugineigula* (Pelzeln, 1858) - S Minas Gerais and S Rio de Janeiro to S Rio Grande do Sul, in SE Brazil.

**Descriptive notes.** 16-18 cm; 24-25 g. Medium-sized thornbird with orange to red eyes and somewhat unusual plumage pattern. Nominant race has indistinct dull rufous-brown supercilium, darker brown lores and postocular line darker, rest of face rufescent brownish; forehead and forecrown bright rufous; rest of crown, back and rump rather dark brownish-olive, uppertail-coverts slightly tinged chestnut; wings mostly dull warm brown, brighter at bases of remiges and duller at tips; tail graduated, rufous; throat dark rufous, blending to olivaceous brown on underparts, palest in centre of belly; iris orange; upper mandible black,

lower mandible grey; tarsus and toes greenish-grey to grey. Sexes alike. Juvenile undescribed. Race *ferrugineigula* has red iris, rufous on crown more extensive, tail brown with rufous outer rectrices, orange-rufous of throat extending to breast, whitish belly, warmer and browner flanks and undertail-coverts. VOICE. Song (nominate race) described as a series of introductory notes on same pitch followed by descending series of loud notes, "chree, chree, chree-tséeéh-tséeéh-tséeéh", sometimes as duet; *ferrugineigula* song as series of loud ringing notes introduced by 1-2 softer notes, "ku, keeé-keeé-keeé-keeé-keeé-kuh".

**Habitat.** Montane evergreen forest, tropical lowland evergreen forest, and secondary forest; in S of range (*ferrugineigula*) freshwater marshes, riparian thickets, gallery forest, swampy woodland, dense second growth. From near sea-level to 800 m.

**Food and Feeding.** Little known. Seen singly or in pairs; evidently gleans arthropods from foliage and branches in dense undergrowth.

**Breeding.** Season probably during austral spring-summer. Presumably monogamous. Nest a large boot-shaped mass c. 40 cm long and 30 cm wide, of usually thorny sticks, inner chamber lined with grasses, usually (perhaps always) with smaller antechamber, suspended from branch tip. Clutch possibly 3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Uncommon. Occurs in several protected areas, e.g. Serra dos Órgãos National Park. This species' restriction to narrow band of lowlands of SE Brazil could render it vulnerable in the future.

**Bibliography.** Belton (1984), Cordeiro (2001), Cory & Hellmayr (1925), Ferreira de Vasconcelos & Melo-Júnior (2001), Goerck (1999a), Ihering (1900), Parrini *et al.* (1998), Pinto (1978), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## Genus *CLIBANORNIS*

P. L. Sclater & Salvin, 1873

## 160. Canebrake Groundcreeper

### *Clibanornis dendrocolaptoideus*

**French:** Synallaxe des bambous

**German:** Halsflecken-Bündelnister

**Spanish:** Espinero Tacuatí

**Taxonomy.** *Anabates dendrocolaptoideus* Pelzeln, 1859, River Yapó, Curytiba, and Boqueirão, Paraná, Brazil.

No obvious close relatives; formerly thought to be close to *Cinclodes*. Sometimes placed in genus *Phacellodomus*, but vocal and plumage differences support treatment in monotypic genus.

**Distribution.** SE Brazil (S São Paulo S to N Rio Grande do Sul), E Paraguay (records from Caazapá, Alto Paraná, and possibly S Caaguazú) and NE Argentina (Misiones).

**Descriptive notes.** 21-22 cm; 52-54 g. Relatively large furnariid. Narrow greyish or buff-grey supercilium broadens and becomes more conspicuous posteriorly; lores dark brown, rest of face dark dull reddish-brown; crown dark chestnut-brown, back and rump rufescent brown, uppertail-coverts rufous-brown; wing-coverts and remiges rufescent brown; tail with rectrices slightly stiffened basally, slightly blunt at tips, central pair dull rufous-brown, rest rufous-chestnut; throat white, blackish markings at side; breast and belly dull greyish, sides rufous-brown, flanks and undertail-coverts ochraceous brown; iris brown; bill

black; tarsus and toes olive-green to greenish-grey. Sexes alike. Juvenile lacks dark feather tips at side of throat, throat washed buff, breast faintly mottled buff, belly greyer. VOICE. Song described as series of loud staccato notes that starts with squeaky, dry "chk" notes, changes half-way through to higher-pitched, faster, squeakier notes; also as "chet, chet, chet-chit-chit", sometimes ending in higher and sharper note.

**Habitat.** Montane evergreen forest and tropical lowland evergreen forest, mostly in hilly terrain at forest edge or in tall second growth; in Brazil, bamboo thickets and dense vegetation in ravines near streams. Habitat preferences in Paraguay and Argentina not understood. From near sea-level to 1200 m.

**Food and Feeding.** Largely undescribed. Usually observed in pairs, in dense undergrowth; presumably gleans arthropods on or near ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Atlantic Forest Lowlands EBA. Considered mostly rare within its small range. Population estimated at 2500-10,000 individuals at end of 20th century; declining owing to habitat destruction. Although difficulty in detection may lead to underestimation of numbers, it may be naturally rare because of restriction to some specific micro-habitat. In Brazil, present in Iguaçu National Park and in Serra da Graciosa Environmental Protection Area; fairly common near Curitiba, in Paraná, and near Urubici, in Santa Catarina; not recorded in Rio Grande do Sul since 1973. In Argentina, present in Iguaçu National Park, Uruguá-i and La Araucaria Provincial Parks, and San Antonio Strict Nature Reserve. In Paraguay, recorded in Caaguazú National Park and reported from La Golondrina Private Nature Reserve, but all records from that country are either old or single observations; intensive surveys using playback have failed to find any resident population; not recorded in Alto Paraná since before 1914. General destruction and degradation of forest habitat pose major threats.

**Bibliography.** dos Anjos & Boçon (1999), Belton (1984), Brooks, Barnes *et al.* (1993), Brooks, Clay *et al.* (1995), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Collar & Andrew (1988), Cordeiro (2001), Cory & Hellmayr (1925), Hayes (1995), Lowen, Bartrina, Brooks *et al.* (1996), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1997), Mazar Barnett & Pearman (2001), Naka *et al.* (2000), Narosky *et al.* (1983), Pearman (1994g), de la Peña (1988), Pinto (1978), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Whitney (2003c).

## Genus *ANUMBIUS* d'Orbigny & Lafresnaye, 1838

## 161. Firewood-gatherer

### *Anumbius annumbi*

**French:** Annumbi fagoteur

**German:** Weißkehl-Bündelnister

**Spanish:** Leñatero

**Other common names:** Wood-gatherer

**Taxonomy.** *Furnarius annumbi* Vieillot, 1817, Paraguay.

No obvious close relatives. Proposed race *machrisi*, described from Goiás (Brazil), has been shown not to be diagnosable. Monotypic.

**Distribution.** SE Brazil (Goiás and Minas Gerais S to Rio Grande do Sul), C & E Paraguay, N & E Argentina (Chaco and Misiones S to NE Chubut) and Uruguay.

**Descriptive notes.** 18-20 cm; 27-45 g. Unusual furnariid with striped back and long, "spiny" tail. Has conspicuous broad whitish supercilium; postocular stripe medium brownish, rest of face light brownish to greyish-brown; forehead dull rufous, blending to dull brown or sandy brown crown with narrow blackish streaks, these fading on hindneck and upper back, then coalescing into broader longer streaks on rest of dull brown back; rump dull pale brown, long uppertail-coverts dark brownish with lighter brownish margins; wings mostly dull brown, some darker centres on coverts and darker tips of remiges; tail graduated, central rectrices slightly stiffened basally and with webs attenuated to a point at tip, others not so pointed, central pair dark brownish, remainder blackish-brown with

Song, often given as duet, described as a fast, rough, bubbly, accelerating, descending series of trilled notes ending with lower-pitched rattle, "chit, chit, chit, che-che-che-ee-ee-ee-ee"; call a sharp "tschick".

**Habitat.** Low, seasonally wet grassland, pastures/agricultural land, second-growth scrub; acacia savanna, grassland, pastureland, and edge of open woodland, including hedgerows and groves around farmhouses; from near sea-level to 1000 m.

**Food and Feeding.** Recorded dietary items are Coleoptera (*Aphodius* and *Curculionidae*), Hemiptera, Diptera larvae, and seeds. Usually in pairs, and often in small groups (possibly nest helpers). Gleans items from ground and up to low vegetation; perhaps mostly terrestrial.

**Breeding.** Season during austral spring-summer; eggs in Sept-Feb and nestlings in Sept-Jan in Argentina; double-brooded. Presumably monogamous. Nest a cylindrical mass c. 50-110 cm high and 30-40 cm wide (occasionally nearly twice those dimensions), of carefully interwoven, usually thorny twigs, main axis vertical or slanted, entrance hole at or near top, interior tunnel to chamber starts straight but then curves, tunnel or entrance hole sometimes lined with bits of glass, feathers and threads, nest-chamber 14-20 cm across, near bottom, lined with plant fibres, feathers, twigs and sometimes inflorescences; usually placed 1-4 m (rarely, to 24 m) above ground among branches, conspicuously in isolated tree or bush, usually thorny, or on crossbar of telephone pole or other man-made object, and often adjacent to old nests from previous years; nest possibly sometimes reused in subsequent years. Clutch 3-5 eggs, possibly sometimes 6; incubation period c. 16 days; nestling period c. 17-18 days; young may accompany parents during second nesting, occasionally help with nest-building, but generally expelled from natal territory within 1 month of fledging.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common. Occurs in a number of protected areas, including Itatiaia, Aparados da Serra and Serra da Canastra National Parks, in Brazil, and Esteros del Iberá National Park, in Argentina. Tolerates at least moderate grazing and other anthropogenic disturbance; presumably benefits to a degree from deforestation.

**Bibliography.** Anon. (2003d), dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Aravena (1928), Belton (1984), Brooks (1997), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1979d), Cory & Hellmayr (1925), Cuervo (1985), Fraga (1979), Friedmann (1927), Hayes (1995), Mason (1985), Mazar Barnett & Pearman (2001), Melo-Júnior *et al.* (2001), Narosky *et al.* (1983), Nores, A.I. ## Genus *CORYPHISTERA* Burmeister, 1860

### 162. Lark-like Brushrunner

*Coryphistera alaudina*

French: Annumbi alouette German: Chaco-Buschläufer Spanish: Espinero Crestudo

**Taxonomy.** *Coryphistera alaudina* Burmeister, 1860, no locality = near Paraná, Brazil.

No obvious close relatives. Validity of race *campicola* questioned by some authors; may represent only clinal extreme in variation, and this suggested by mensural data, but quantitative analysis of plumage characters required. Two subspecies tentatively recognized.

**Subspecies and Distribution.**

*C. a. campicola* Todd, 1915 - SE Bolivia (Chuquisaca, S Santa Cruz) and W Paraguay.

*C. a. alaudina* Burmeister, 1860 - S Bolivia (Tarija), N & E Argentina (Salta and Chaco S to Mendoza, La Pampa and S Buenos Aires), NW Uruguay and extreme SE Brazil (W Rio Grande do Sul).

**Descriptive notes.** 15-17 cm; 27-42 g. Crested, terrestrial furnariid with unusual facial pattern, general appearance very like that of a lark (*Alaudidae*). Has whitish area extending from eye to supraloral area, somewhat crescent-shaped whitish area below eye and including anterior portion of auriculars, dull brownish lores and area behind eye, posterior part of auriculars cinnamon-rufous with narrow connection to lores (thus outlining white area below eye); forehead rufescent brownish, blending to very dark brown crown with feathers elongated into prominent crest; hind-crown and upper back pale dull brown with

vague darker streaking, streaks becoming broader and much darker on rest of back, rump and uppertail-coverts; wing-coverts dark fuscous brown, primary coverts blackish, remiges blackish with strongly contrasting rufescent inner margins (wider at bases), pale buff outer margins; tail slightly rounded to almost square, central rectrices dark fuscous brown with dull buff margins, remainder mostly rufous with progressively decreasing amounts dark fuscous brown edging distally; chin whitish; throat whitish, dull rufous streaking increasing in density posteriorly; breast whitish with broad, somewhat blurred dull rufous streaks, these fading and becoming browner on upper belly, flanks and undertail-coverts, almost unstreaked centre of belly; iris dark brown to light grey-

ish-brown; upper mandible brownish to yellowish-brown, usually darker tip, lower mandible pinkish-grey to yellow-brown, sometimes darker at tip; tarsus and toes dull orange to greyish-tan to light brown (source of variation uncertain). Sexes alike. Juvenile has shorter crest, less distinct streaks. Race *campicola* has paler streaks on underparts, some pale rufous edging at bases of crest feathers, more buff edging on back and rump feathers. Voice. Primary vocalization described as a high-pitched, tremulous, tinkling trill, "rrrrrew" or "croee, crriiii"; calls include variety of low buzzy trills and squeaky notes.

**Habitat.** Arid lowland scrub; arid Chaco and *monte* woodland; ranges into adjacent agricultural fields. From near sea-level to 500 m.

**Food and Feeding.** Recorded food items are Coleoptera (especially *Curculionidae*; also *Elateridae*), Orthoptera, Hemiptera, spiders, and snail shells; some stomachs contained almost entirely ants (*Formicidae*). Occurs in groups of 3-7 in breeding season; flocks of 12-15 during non-breeding season, when also in mixed-species flocks. Largely terrestrial. Gleans arthropods from ground, usually near cover; walks, and scratches ground, sometimes using both feet; occasionally flakes or tosses dung, or turns it over with feet.

**Breeding.** Season during austral spring-summer; eggs from late Sept to Jan and nestlings in Oct in Argentina. Perhaps monogamous; "extra" birds in breeding-season social group, unless helpers, could suggest non-monogamous system; as many as 8 individuals seen to enter a single nest, at least one suspected case of more than one female laying in same nest. Nest a globular mass c. 30-100 cm in diameter, slightly elongated vertically, of tightly interwoven, thorny twigs and branches, some as long as 100 cm, interior tunnel 11-18 cm long, often winding, tunnel often lined with objects such as old butterfly chrysalids, desiccated frog skeletons, and bits of coloured glass, leads from top of nest to internal chamber, latter with floor of grasses and feathers; placed c. 2-5 m up on low branch in tree, occasionally on top of old nest. Clutch 3-4 eggs, possibly sometimes 5.

**Movements.** Mainly resident; some local movement to N in austral winter.

**Status and Conservation.** Not globally threatened. Fairly common to abundant in much of its range. Occurs in several protected areas, e.g. Chancani Natural Reserve, in Argentina.

**Bibliography.** Belton (1984), Canevari *et al.* (1991), Capurro & Bucher (1986), Chebez *et al.* (1999), Contreras (1980c), Cory & Hellmayr (1925), Cuervo (1985), Esteban (1951b), Fraga (1979), Friedmann (1927), Guerrero & Arambiza (2001), Hayes (1995), Kratter *et al.* (1993), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Nores *et al.* (1983), Ochoa (1971), Olrog (1963a), Partridge (1953), de la Peña (1987, 1988, 1995), Pinto (1978), Remsen (2003a), Remsen & T aylor (1989), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Wetmore (1926).

## Genus *SIPTORNIS* Reichenbach, 1853

### 163. Spectacled Prickletail

*Siptornis striaticollis*

French: Pseudosittine à collier German: Brillenschlüpfer Spanish: Curutié Frontino  
Other common names: Stripe-necked Spinetail

**Taxonomy.** *Synnalaxis* [sic] *striaticollis* Lafresnaye, 1843, Colombia = Bogotá.

No obvious close relatives. Two subspecies recognized.

**Subspecies and Distribution.**

*S. s. striaticollis* (Lafresnaye, 1843) - E Andes of Colombia (W slope in Cundinamarca and head of Magdalena Valley in Huila, and E slope in E Cauca and W Caquetá).

*S. s. nortoni* Graves & Robbins, 1987 - Andes of Ecuador (E slope) S to extreme N Peru (N Cajamarca).

**Descriptive notes.** 11-12 cm; 12-13 g. A tiny furnariid with plumage pattern somewhat like *Xenops*. Nominant race has short supercilium and partial eyering whitish, lores dull fuscous, auriculars rufescent with tawny shaft streaks; crown dark reddish-brown with hint of pale shaft streaking, accentuated on hindcrown; upperparts rich rufescent brown, becoming redder posteriorly, uppertail-coverts tinged chestnut; wing-coverts dark chestnut, primary coverts blackish-brown, bend of wing pale cinnamon, rufescent edges of inner remiges, mainly dark fuscous outer remiges; tail slightly graduated, central rectrices slightly stiffened

basally, shafts virtually devoid of barbs for distal 2 mm, giving "spiny" appearance, reddish-chestnut; chin buff, grizzled; malar area brown with pale buff streaks; throat and upper breast greyish olive-brown with fine pale buff streaks, narrow area on side of breast pale cinnamon, rest of underparts greyish olive-brown; iris brown; upper mandible dark brown, lower mandible pinkish with greyish tip; tarsus and toes greyish-green to olive-yellow. Sexes alike. Juvenile has crown rufescent brown, like back, broader and more extensive streaks on underparts. Race *nortoni* has much more conspicuous buff-whitish streaking on throat and breast, less white in face, paler lores. Voice. High-pitched trill, possibly as song.

**Habitat.** Montane evergreen forest; 1300-2400 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks, in mid-storey, occasionally to subcanopy. Climbs and hitches along small branches, sometimes hanging upside-down acrobatically. Gleans and probes in moss, bark crevices, dead leaves, epiphytes, and undersides of large green leaves (*Cecropia*); occasionally pecks at branches, using tail as brace.

**Breeding.** Season not documented. Presumably monogamous. Nest a spherical mass of moss and other plant material, with bottom entrance, placed at or near tip of lateral branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon. Seems to be rather local in distribution.

**Bibliography.** Cory & Hellmayr (1925), Eley *et al.* (1979), Fjeldså & Krabbe (1990), Graves & Robbins (1987), Hilty & Brown (1986), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Rahbek *et al.* (1995), Remsen (2003a), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Stotz *et al.* (1996).

Genus *METOPOTHRIX*

P. L. Sclater & Salvin, 1866

164. Orange-fronted Plushcrown

*Metopothrix aurantiaca*

**French:** Tête-de-feu pelucheux    **German:** Orangestirn-Bündelnister    **Spanish:** Coronafelpa  
**Other common names:** Orange-fronted Softtail

**Taxonomy.** *Metopothrix aurantiacus* Sclater and Salvin, 1866, Sarayacu, Rio Ucayali, Loreto, Peru.

Highly distinctive plumage so different from that of others in family that its placement in Furnariidae was once questioned. Possible link to *Acrobatornis* suggested by nest architecture and voice. Monotypic.

**Distribution.** SE Colombia (Putumayo, Amazonas), E Ecuador, E Peru, W Brazil (E to lower R Juruá and upper R Purús, S to Acre), and NE Bolivia (NE Beni).

**Descriptive notes.** 11 cm; 10-12 g. Diminutive furnariid, the only one with yellow and greenish plumage and yellow-orange legs. Has greenish-yellow supercilium behind eye, becoming yellow above eye, merging with yellow forehead, lores and indistinct eyering; faint narrow eyeline dark greenish-olive, auriculars dull greenish-olive; forehead bright yellow, blending to narrow band of orange, then to greenish-olive crown and upperparts, rump faintly paler; wings mostly dark olive fuscous, coverts and remiges with pale dull yellow-green margins, primary coverts dark fuscous; tail graduated, rectrices slightly stiffened basally, slightly pointed, dull greenish-olive; throat yellow, blending to dull yellowish-green breast, flanks and undertail-coverts, slightly paler on belly; iris brown to dark brown to

grey; upper mandible black, lower mandible black to grey; tarsus and toes bright yellow-orange to yellow. Sexes alike. Juvenile (or possibly immature) has reduced orange and yellow on face. **Voice.** Song a slightly descending series of 3-5 evenly spaced, high, thin notes, lasts 1.5-2.5 seconds; call described as thin "tsweet-tsweet", often repeated.

**Habitat.** River-edge forest, old and middle-aged river islands, tall second growth, and edges of clearings in *várzea* and *terra firme* forest, rarely far from rivers; 150-650 m.

**Food and Feeding.** Mainly arthropods; recorded once as feeding on fruit, and once observed to

feed at flowers (not known if for nectar or for insects). Occurs in pairs or in presumed family groups of 3-5 individuals, often in mixed-species flocks. Forages from mid-storey to canopy. Gleans arthropods from leaves (especially undersides) and twigs, frequently hanging acrobatically directly from leaf.

**Breeding.** Nest-building observed in Jan in Ecuador. Nest c. 50 cm in diameter, a mass of sticks, some c. 25 cm long, with side entrance, placed 4-20 m above ground. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon but locally common. Occurs in several protected areas, including Cuyabeno Reserve, in Ecuador, and Manu National Park and Biosphere Reserve, in Peru. May benefit from limited deforestation, resulting in increasing its preferred edge habitats.

**Bibliography.** Berlepsch (1903), Cory & Hellmayr (1925), Feduccia (1970b), Fraga (1992), Gyldenstolpe (1951), Hilty & Brown (1986), Pacheco (1995), Pacheco *et al.* (1996a), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg, G.H. ## Genus *XENERPESTES* Berlepsch, 1886

### 165. Double-banded Greytail

#### *Xenerpestes minlosi*

**French:** Queue-grise des feuilles **German:** Flügelbindenschlüpfer **Spanish:** Colagris Norteño  
**Other common names:** Double-banded Softtail

**Taxonomy.** *Xenerpestes minlosi* Berlepsch, 1886, near Bucaramanga, Santander, Colombia. Relationships of genus unclear; plumage, nest architecture and placement, and voice suggest possible relationship to *Acrobatornis*. Sometimes treated as forming a superspecies with *X. singularis*, the two differing in elevational distribution. Two subspecies recognized.

#### **Subspecies and Distribution.**

*X. m. umbraticus* Wetmore, 1951 - E Panama (Darién), W Colombia (Caribbean lowlands E to R Sinu, and Pacific lowlands) and NW Ecuador (Esmeraldas, NW Pichincha).

*X. m. minlosi* Berlepsch, 1886 - Caribbean lowlands of Colombia E to middle Magdalena Valley (NW Santander, W Boyacá).

**Descriptive notes.** 11-12 cm. Tiny, warbler-like furnariid. Has creamy white supercilium, olive-buff lores, dark grey line behind eye, greyish rest of face; crown blackish, blending to grey back, rump and uppertail-coverts; wing-coverts dark grey with two conspicuous white wingbars, bend of wing yellowish, remiges dark fuscous; tail slightly rounded, dark grey; throat and underparts creamy whitish, some greyish flecking on breast, olive-buff undertail-coverts; iris light brown; upper mandible dark brown, lower mandible greyish-white; tarsus and toes greyish-brown. Sexes alike. Juvenile has greyer underparts, less distinct supercilium, lacks wingbars. Race *umbraticus* has darker upperparts, lacking definite streaks on crown, darker wings and tail. **Voice.** Song a long, dry, extremely rapid chattering trill on same pitch, increasing in volume, lasts 3-12 seconds; call a sharp, thin, inflected note.

**Habitat.** Hilly tropical evergreen forest, also tall second growth; recorded from near sea-level to 900 m.

**Food and Feeding.** Arthropods. Usually in pairs or small groups, sometimes in mixed-species flocks. Forages from mid-storey to canopy, especially in dense vine tangles. Gleans items acrobatically, often from undersides of leaves, twigs and dead leaves, sometimes flowers; sometimes creeps briefly, like a *Xenops*.

**Breeding.** No information. A large stick nest with side entrance, found in E Panama, may have been of this species.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Status not well known; considered rare to locally uncommon, but this may be in part a reflection of the difficulty in detecting this species. Recently listed as vulnerable in Ecuador. No data on population size, trends or specific threats; deforestation probably the main threat.

**Bibliography.** Anon. (2003g), Berlepsch (1903), Cory & Hellmayr (1925), Delgado (1985), Hilty & Brown (1986), Pacheco *et al.* (1996a), Parker & Parker (1980), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Stotz *et al.* (1996), Vaurie (1971b), Wetmore (1951, 1972), Whitney *et al.* (1996).

### 166. Equatorial Greytail

#### *Xenerpestes singularis*

**French:** Queue-grise d'Équateur **German:** Roststimschlüpfer **Spanish:** Colagris Sureño  
**Other common names:** Equatorial Softtail

**Taxonomy.** *Synallaxis singularis* Taczanowski and Berlepsch, 1885, Mapoto, 7000 feet [c. 2130 m], Ambato, Tungurahua, Ecuador.

Relationships of genus unclear; plumage, nest architecture and placement, and voice suggest possible relationship to *Acrobatornis*. Sometimes treated as forming a superspecies with *X. minlosi*, the two differing in elevational distribution. Monotypic.

**Distribution.** Andes of Ecuador (E slope S from W Napo) S to N Peru (Cajamarca, San Martín).

**Descriptive notes.** 11-12 cm; 11-15 g. Tiny, warbler-like furnariid. Has yellowish-white supercilium narrowing and disappearing in front of eye, lores grizzled buff and greyish, broad olive-grey postocular band; forehead dull rufous with sharply defined blackish streaking, fading to olive-grey crown with vague blackish streaking; back olive-grey, rump slightly paler; wings mostly dark fuscous grey, blackish primary coverts; tail graduated, rectrices perhaps slightly stiffened, nearly rounded, colour as rump; malar area, throat and upper breast whitish with faint grey flecking, intensifying into narrow streaks laterally; lower

breast whitish with broader, more distinct dark grey streaks, these becoming longer on upper belly; lower belly and undertail-coverts more solidly greyish with vague paler streaks; iris chestnut to light brown to pale grey-brown (source of variation uncertain); upper mandible black to horn, lower mandible pale grey to pinkish; tarsus and toes olive-green to yellowish-green. Sexes alike. Juvenile undescribed. **Voice.** Song a dry trill, almost insect-like, c. 5 seconds long; call a dry "tsit".

**Habitat.** Montane evergreen forest, usually tall and epiphyte-laden; 1030-1700 m, occasionally to possibly 2140 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks, in canopy. Gleans food items from leaves and their bases, and from small branches, often by hanging upside-down and with other acrobatic manoeuvres; occasionally hitches along a branch.

**Breeding.** No published information. Nest-building reported in Jan in Ecuador. One hitherto unpublished record of a nest in Peru, a large structure c. 15 × 15 × 25 cm, somewhat like inverted light bulb in shape, made of sticks c. 15 cm in length or longer and c. 0.5 cm in diameter, suspended c. 10 m above ground from branch in isolated tree in roadside light-gap, active, at least 2 birds entering and leaving nest; reported nest under construction (almost completed) in Ecuador, roughly cylindrical, c. 10 × 10 × 20 cm, entrance on end, of sticks similar in size to above-mentioned, placed c. 10 m in hanging branch, both birds present, one seemed to be doing most of work.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Ecuador-Peru East Andes EBA. Rare to locally uncommon; as a canopy species, however, it is difficult to detect and perhaps often overlooked. Occurs in Podocarpus National Park, in Ecuador. Lower montane forest throughout Andes is especially prone to clearance, and this and other species restricted to this elevational zone have suffered tremendous habitat loss.

**Bibliography.** Anon. (2003g), Berlepsch (1903), Cory & Hellmayr (1925), Pacheco *et al.* (1996a), Parker & Parker (1980), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rogers & Walker (2003), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vaurie (1971b).

## Genus *ACROBATORNIS* Pacheco *et al.*, 1996

### 167. Pink-legged Graveteiro

#### *Acrobatornis fonscae*

**French:** Synallaxe à pattes roses **German:** Plantagenschlüpfer **Spanish:** Graveteiro

**Taxonomy.** *Acrobatornis fonscae* Pacheco *et al.*, 1996, Serra das Lontras, c. 550 m, above Itatingui, 15°11' S, 39°23' W. Municipality of Arataca, Bahia, Brazil.

No obvious close relatives. Plumage, nest architecture and placement, and voice suggest relationship to *Xenerpestes*; morphology, nest architecture and voice also suggest possible link to *Metopothrix* or *Margarornis*; song and nest structure suggest possible link to some *Asthenes* or *Cranioleuca*. The only furnariid with juvenile plumage radically different from adult. Monotypic.

**Distribution.** SE Bahia, in E Brazil.

**Descriptive notes.** 13-14 cm; 14-15 g. Distinctive furnariid, the only one with plumage entirely grey and black and legs bright pink. Has broad grey supercilium becoming very narrow in front of eye, merging with grizzled black and grey loreal region and forehead; rest of face slightly darker grey; forehead black with grey spotting, blending to black crown; back grey with black feather margins, producing weakly scalloped appearance, lower back and uppertail-coverts paler grey; wing a complex pattern of black and grey; tail strongly graduated, rectrices slightly stiffened basally, vanes greatly reduced towards tip, outer webs of central rectrices very

narrow (producing spiny and forked appearance), grey, becoming black distally; throat and breast grey with indistinct paler streaks, these becoming more conspicuous on belly, lower belly slightly tinged olive, flanks and undertail-coverts grey; iris pale grey; upper mandible dark brown to dusky horn, lower mandible pinkish; tarsus and toes bright pink. Sexes alike. Juvenile has pattern of adult, but grey largely replaced by reddish-yellow. **Voice.** Song 4-8 seconds long, 2-4 irregularly spaced sharp notes followed by series of piercing notes, accelerating and fading into trill, similar in quality to songs of *Asthenes dorbignyi* and *A. baeri*; song in response to playback longer, up to 12 seconds, often stuttering notes included, terminal trill faster, in duet, presumed male gives normal song, female interjects sharper notes similar to those that introduce song. Call a short, sharp note; occasional chattering series of 10-12 notes during greeting between partners.

**Habitat.** Found only in thinned forest dominated by Leguminosae (*Erythrina verna*, *Senna multijuga*, *Schizolobium parahyba*, *Inga* species) that shades cocoa plantations, from near sea-level to 550 m. Original natural habitat presumably moist, semi-deciduous lowland Atlantic Forest, now destroyed.

**Food and Feeding.** Recorded dietary items include Coleoptera (including families Curculionidae, Staphylinidae), Lepidoptera larvae and adults, ants and winged Hymenoptera, also Hemiptera, Homoptera, insect eggs, oothecae of Orthoptera, and spiders. Forages in pairs or family groups, almost always in mixed-species flocks, in canopy and subcanopy. Most foraging manoeuvres consist of hitching along undersides of branches up to 8 cm in diameter and hanging acrobatically upside-down from branches. Gleans arthropods from live foliage and flowers, and probes for items in moss on branches and bark on dead branches.

**Breeding.** Season probably in austral spring, especially Sept-Oct; nestlings in Oct. Nest helping recorded; young seen to assist in nest construction, and individual in immature plumage observed while feeding begging juvenile, which also being fed by adults. Nest an oval or nearly rectangular mass of sticks, placed usually 20-30 m up in fork of tree branch or on top of nearly horizontal branch. No further information.

#### **Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** First discovered as recently as 1994. Known from many sites but all in only one very small area, and no formal protection at any localities. Total population estimated at 2500-10,000 individuals; declining as a result of habitat destruction. Cur-

rently known exclusively from the canopy of forest shading cocoa plantations, extent of which are at the mercy of fluctuating cocoa prices and competing land uses. Numbers certainly reduced dramatically during 20th century following massive habitat destruction in region; virtually all forest below 500 m, presumably the species' original habitat, has been destroyed completely or thinned dramatically to shade plantations, and remnant population of this furnariid is probably at upper elevational limit of its former range. Its survival seems entirely dependent on a man-made habitat to which it has adapted, but persistence of habitat itself depends on patterns of human land use, local profitability of plantations, and global market for cocoa. For example, some plantations already cleared and others changed to different crops following fungal disease that reduced cocoa productivity in early 1990s.

**Bibliography.** Cordeiro (2001), Pacheco *et al.* (1996a, 1996b), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Whitney *et al.* (1996).

## Genus *PREMNORNIS* Ridgway, 1909

### 168. Rusty-winged Barbtail

#### *Premnornis guttuligera*

**French:** Anabassite à gouttelettes **Spanish:** Subepalo Alirrojizo  
**German:** Rostschwingen-Blattsphäer  
**Other common names:** Spotted Treerunner

**Taxonomy.** *Thripophaga guttuligera* P. L. Slater, 1864, interior of Colombia = Bogotá. Genus probably closest to *Premnoplex*, and this supported by anatomical data; both genera merged with *Margarornis* by some authors. Two subspecies recognized.

#### **Subspecies and Distribution.**

*P. g. venezuelana* Phelps, Sr. & Phelps, Jr., 1956 - NW Venezuela (Perijá Mts. and Andes of SW Táchira).

*P. g. guttuligera* (P. L. Slater, 1864) - Andes of Colombia (all three ranges), Ecuador and Peru (S to Puno).

**Descriptive notes.** 13-14 cm; 13-17 g. Small furnariid with plumage pattern that recalls that of some *Xiphorhynchus* woodcreepers. Nominative race has pale buffish or brownish-buff supercilium joining spotted collar posteriorly, broad dark brown postocular band, rest of face streaked dark brown and buff; crown dark olive-brown, paler spotting on forehead, slightly darker margins on some feathers producing faintly scalloped pattern; neck side and upper back brownish with pale dull buff spotting, blending to browner back without spots; rump faintly tinged rufescent, uppertail-coverts chestnut; wing-coverts dark brownish

with broad rufescent brown margins (form indistinct wingbars), primary coverts dark brown, remiges dark fuscous with rufescent margins; tail graduated, broad rectrices abruptly attenuated at tips, lack barbs for distal 1 mm (short "spines" difficult to see in field), chestnut; throat golden-buff with faint dark flecking; breast dark brownish with striking teardrop-shaped golden-buff spots, these lengthening into short streaks on upper belly, vanishing into lower belly; flanks and undertail-coverts rufescent brown; iris brown to dark brown; upper mandible black to dark brownish, lower mandible pinkish to pinkish-grey to dull ivory, sometimes with dark tip; tarsus and toes grey to blue-grey to pinkish-grey. Sexes alike. Juvenile has buff streaks on back and rump, more heavily spotted underparts washed rufous. Race *venezuelana* has darker, more olivaceous crown and back (less rufous tint), blacker margins on crown feathers. **Voice.** Seems to be perhaps the most characteristically silent furnariid. Fast, bouncy, accelerating "tsi-tsi-tsi-si-si-si-si-si-si", c. 1-3 seconds long, presumably as song; call note described as sharp "tseep or "tsip", sometimes run into series.

**Habitat.** Montane evergreen forest, mostly at of 2000-2750 m; locally down to 1300 m in Peru.

**Food and Feeding.** Arthropods. Generally forages singly, usually in mixed-species flocks, from understorey to mid-storey. Hops and clambers along branches, does not normally use tail for support. Less acrobatic than *Premnoplex* or *Margarornis*, feeding more like a *Philydor* foliage-gleaner. Gleans items from mossy branches and twigs, dead leaves and live foliage; sometimes "burrows" into large clumps of moss or debris.

**Breeding.** Fledglings in Dec in C Colombia; in Ecuador, fledglings in Sept in NW, Jan-Feb and Sept in NE and Nov in S. Presumably monogamous. Nest not described. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common. Occurs in a number of protected areas, e.g. La Planada Nature Reserve, in Colombia, and Rio Palenque Science Centre, in Ecuador.

**Bibliography.** Cory & Hellmayr (1925), Cuervo *et al.* (2003), Ejlsd & Krabbe (1990), Graves (1985), Hilty (2003a), Hilty & Brown (1983, 1986), Mayr & Phelps (1967), Meyer de Schauensee & Phelps (1978), Miller (1963), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Peña (1997), Phelps & Phelps (1956), Remsen (2003a), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rudge & Raikow (1992b), Salaman (1994), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Slotz *et al.* (1996), Willis & Schuchmann (1993), Zimmer (1934e).

## Genus *PREMNOPLEX* Cherrie, 1891

### 169. Spotted Barbtail

#### *Premnoplex brunescens*

**French:** Anabassite tachetée **Spanish:** Subepalo Moteado  
**German:** Westlicher Fleckenstachelschwanz

**Taxonomy.** *Margarornis brunescens* P. L. Slater, 1856, "Bogotá".

Genus probably closest to *Premnornis*, and this supported by anatomical data; both genera merged with *Margarornis* by some authors. Forms a superspecies with *P. tatei*, and sometimes treated as conspecific. Populations in Trujillo and Barinas (Venezuela) tentatively placed with nominate race; further study required. Proposed Panamanian races *albescens* (E Darién) and *mnionophilus* (Cerro Campana) considered indistinguishable from nominate, and *distinctus* (Veraguas) indistinguishable from *brunneicauda*. Five subspecies recognized.

#### **Subspecies and Distribution.**

*P. b. brunneicauda* (Lawrence, 1865) - mountains of Costa Rica and W Panama (E as far as Veraguas).

*P. b. brunescens* (P. L. Slater, 1856) - cerros Tacarcuna, Pirre and Mali and Serranía de Majé (extreme E Panama and NW Colombia), Perijá Mts and Andes of W Venezuela (Trujillo, Barinas, Mérida, Táchira), S (in all three ranges in Colombia, also Macarena Mts, in S Meta) to Ecuador and Peru (S to Cuzco).

*P. b. coloratus* Bangs, 1902 - Santa Marta Mts of N Colombia.

*P. b. rostratus* Hellmayr & Seilern, 1912 - coastal mountains of N Venezuela (Lara E to Miranda and Aragua).

*P. b. stictonotus* (Berlepsch, 1901) - Andes from S Peru (Puno) S to W & C Bolivia (S to Cochabamba).

**Descriptive notes.** 13-15 cm; 14-19 g. Small, dark furnariid with a rich ventral pattern. Nominative race has a series of closely spaced tawny-ochraceous spots above and behind the eye, forming a narrow supercilium; lores dull ochraceous mixed with brownish, auriculars dark brown with tawny-ochraceous streaks; narrow and weakly defined rows of small tawny-ochraceous spots on neck extend to meet supercilium; forehead and supraloral area dark grey-brown with tawny-ochraceous spots; crown grey-brown with feathers outlined in blackish (giving scalloped appearance), spots of forehead fading into paler

centres of crown feathers; back dark brown with blackish feather edges, continuing the scalloped theme of crown but less conspicuously, rump tinged chestnut with faint scalloping, uppertail-coverts chestnut-brown; wings mostly dark brown, some darker centres of coverts, darker brown primary coverts; tail graduated, central rectrices slightly stiffened, all rectrices with distal 3-6 mm of shafts lacking barbs, producing very "spiny" appearance, inner webs fuscous brown, outer webs browner; throat tawny-ochraceous with feathers faintly margined dark brown, with brown increasing posteriorly, some birds have whitish throat ("*albescens*"); breast dull brown with conspicuous oblong tawny-ochraceous spots outlined in darker brown, spots lengthen posteriorly and continue into dull brown belly, but become smaller and less conspicuous towards vent, and become streaks (and fade posteriorly) on flanks; undertail-coverts dull brown with faint ochraceous spotting; iris brown to dark brown; upper mandible black to dark brownish, lower mandible pale greyish-pinkish to pale horn, sometimes with dark tip; tarsus and toes dark grey-brown to dark brown. Differs from similar *P. tatei* mainly in having supercilium, throat, and neck and ventral spotting ochraceous (not whitish), breast spots smaller and less dense, bill less deep. Sexes alike. Juvenile has buff shaft streaks on back, heavier scaling on throat, spots on tips of greater wing-coverts, more irregular pattern of spotting on underparts. Race *brunneicauda* differs from nominate in having back more olivaceous brown, tail browner, throat slightly paler, underparts more olivaceous with dark margins of spots less conspicuous; *coloratus* has less rufous-tinged back and uppertail-coverts, browner tail, darker, more ochraceous colour on throat extending farther into upper breast; *rostratus* is evidently like previous, but has longer bill, black tail, darker olive crown, deeper rufous back; *stictonotus* differs from nominate in having conspicuous pale shaft streaks on upper back. **Voice.** Song an explosive, high, dry, thin "eep, eep, eep, ti-ti-ti-ti-ti", trilled at end, also described as short, slightly descending trill sometimes preceded by several emphatic higher-pitched notes, sometimes slowing at end, lasts c. 1-1.5 seconds. Call a distinctive sharp "teep", "teek", or "pseek", often repeated.

**Habitat.** Montane evergreen forest, especially in areas with extensive moss and epiphytes. Mainly 1200-2300 m in Central America; 900-2600 m in Andes, but down to 650 m in W range and locally to 3000 m.

**Food and Feeding.** Reported dietary items include Coleoptera (of families Scarabaeidae, Brentidae), ants and other Hymenoptera, cockroach (Blattodea) eggs, and spiders. Unusual variation in feeding sociality reported from different areas, with some observations that it usually forages alone, whereas others indicate usually in pairs or groups (perhaps family parties), and often in mixed-species flocks. Forages in understorey, occasionally to mid-storey. Climbs and hitches along branches, occasionally vertical ones, and even slender twigs, occasionally using tail for support; occasionally hanging upside-down, and even creeping along underside of branches. Gleans and probes for arthropods on mossy branches, bark crevices, epiphytes and tree trunks.

**Breeding.** Season mainly Mar-Jun in Central America; in Andes, eggs in Mar and Jun in Ecuador, and nestlings in Apr in Colombia and Ecuador. Presumably monogamous. Nest a massive ball c. 30 cm in diameter, of mainly moss, liverworts and lichens, bound with fine rootlets, tubular entrance at bottom, tunnel 8-10 cm long leads to interior chamber 6-8 cm in diameter, lined with rootlets, moss and fine fibres; wedged in crevice or nook in fallen log, loose bark, or occasionally roots, or suspended from end of branches or underside of fallen log, usually within 2-3 m of ground, near or overhanging stream, in area of dense shade. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common, locally uncommon. Occurs in numerous protected areas throughout extensive range, including Tapanti National Park and Monte Verde Forest Reserve, in Costa Rica, Henri Pittier National Park, in Venezuela, La Planada Nature Reserve and Rio Nambi Natural Reserve, in Colombia, and in Machu Picchu Historical Sanctuary, in Peru. Appears to be fairly adaptable; present in fragmented forest.

**Bibliography.** Angehr & Aueca (1997), Angehr & Christian (2000), Anon. (1998a), Chapman (1926), Collins (1972), Collins *et al.* (1991), Cory & Hellmayr (1925), Ejlsd & Krabbe (1990), Graves (1985), Hilty (1997, 2003a), Hilty & Brown (1983, 1986), Marin & Carrión (1994), Mayr & Phelps (1967), Miller (1963), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Powell (1983), Remsen (2003a), Remsen & Traylor (1989), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Rodner *et al.* (2000), Rudge & Raikow (1992b), Salaman (1994), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg (2002), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Slotz *et al.* (1996), Todd & Carriker (1922b), Wetmore (1951, 1972), Willis & Schuchmann (1993), Young *et al.* (1998), Zimmer (1930, 1934e).

## 170. White-throated Barbtail

### *Premnoplex tatei*

**French:** Anabasis à gorge blanche **Spanish:** Subepalo Gorgiblanco  
**German:** Östlicher Fleckenstachelschwanz  
**Other common names:** Paria Barbtail (*pariae*)

**Taxonomy.** *Premnoplex tatei* Chapman, 1925, Mount Turumiquire, 7900 feet [c. 2400 m], north-eastern Venezuela.

Genus probably closest to *Premnornis*, and this supported by anatomical data; both genera merged with *Margarornis* by some authors. Forms a superspecies with *P. brunnescens*, and sometimes treated as conspecific. Two subspecies recognized.

#### Subspecies and Distribution.

*P. t. tatei* Chapman, 1925 - Cordillera de Caripe in NE Anzoátegui and S Sucre, and N Monagas (Cerro Negro), in NE Venezuela.

*P. t. pariae* Phelps, Sr. & Phelps, Jr., 1949 - cerros Humo and Azul, in Paria Peninsula (N Sucre).

**Descriptive notes.** 14-15 cm. Nominate race has whitish supercilium, dark brownish auriculars and neck side streaked whitish; forehead and crown dark grey-brown, feathers outlined in blackish (giving scalloped appearance); upperparts dark grey-brown, tinged rufous; wings mostly dark fuscous; tail graduated, central rectrices slightly stiffened, all with distal 3-6 mm of shafts lacking barbs, producing very "spiny" appearance, dark fuscous; throat to upper breast whitish, rest of underparts dark brownish with whitish streak-like spotting; iris dark brown; upper mandible black, lower mandible pale greyish-pink, often with black tip; tarsus and toes

dark grey-brown to black. Differs from similar *P. brunnescens* primarily in having supercilium, throat, and neck and ventral spotting whitish, breast spots also denser and larger, and bill thicker. Sexes alike. Juvenile undescribed. Race *pariae* described as having crown darker, throat nearly pure buff, underparts more dusky and darker brown, light markings below more extensive, breast with less distinct markings, belly with wider whitish streaks. **Voice.** Song low-pitched, doubled or tripled, whistled notes; also (nominate race) described as bubbly series of low, soft, reedy whistles, "we-whür, we-whür, we-héet", thus unlike that of *P. brunnescens*.

**Habitat.** Montane evergreen forest; wet, mossy forest, especially where dominated by small palms and Arecaceae. At 1100-2400 m; race *pariae* 800-1200 m.

**Food and Feeding.** Arthropods. Forages solitarily or in pairs, possibly regularly in mixed-species flocks, in undergrowth. Gleans items from logs and boulders 0-2-3 m above ground; possibly less acrobatic than *P. brunnescens*.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Caripe-Paria Region EBA. Uncommon to rare, and possibly very local; absent from some apparently suitable areas. Total population estimated at 2500-10,000 individuals; declining as a result of habitat destruction. Formerly fairly common, but numbers have undoubtedly been reduced dramatically by deforestation within its tiny range. Nominate race recorded only once in last 50 years; most surviving forest in Caripe Mts is badly degraded, despite official protection in Cueva del Guácharo National Park. Known localities of race *pariae* almost entirely within Paria Peninsula National Park, but forest in this park, because it receives no proper protection, is being destroyed by burning and cultivation; estimates of up to 2-4 pairs/ha, if correct, suggest high density in remaining habitat. Surveys needed in order to determine more accurately current populations of both races.

**Bibliography.** Boesman & Curson (1995), Chapman (1925), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Colvée (1999), Evans *et al.* (1994), Gabaldón (1992), Hilty (1999, 2003a), Mayr & Phelps (1967), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1949), Renjifo *et al.* (1997), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rodríguez & Rojas-Suárez (1995), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

## Genus RORAIMIA Chapman, 1929

### 171. Roraiman Barbtail

#### *Roraimia adusta*

**French:** Anabasis du Roraima **German:** Tepuistachelschwanz **Spanish:** Subepalo del Roraima

**Taxonomy.** *Synallaxis adusta* Salvin and Godman, 1884, Mount Roraima, 6000 feet [c. 1830 m], Bolívar, Venezuela.

Genus merged into *Margarornis* by some authors, whereas others suspect that it is closer to *Premnoplex* or *Premnornis*; anatomical data are consistent with the idea that all are each others' closest relatives, but that present genus does not fit into any of the others. Species was at one time mistakenly considered to be a race of *Synallaxis cinnamomea*. Four subspecies recognized.

#### Subspecies and Distribution.

*R. a. obscuradorsalis* Phelps, Sr. & Phelps, Jr., 1948 - Cerro Paraque, in SE Venezuela (extreme NW Amazonas).

*R. a. duidae* Chapman, 1939 - tepuis of S Venezuela in C & S Amazonas (Mt Duida, Cerro Huachamacari, Serranía Parí).

*R. a. mayri* Phelps, Jr., 1977 - Cerro Jaua (S Bolívar).

*R. a. adusta* (Salvin & Godman, 1884) - SE Venezuela (Mt Roraima and associated tepuis in SE Bolívar), N Brazil (Mt Roraima) and W Guyana (Mt Tewk-quay).

**Descriptive notes.** 14-15 cm; 14-20 g. Strikingly patterned furnarid that is morphologically similar to a *Margarornis* treerunner. Has broad, conspicuous bright chestnut supercilium extending to nape and mantle, dark blackish-brown lores and auriculars; bright chestnut forehead, dark brown crown, chestnut back, rump and uppertail-coverts; wing-coverts dusky brown with chestnut edges, remiges chestnut-tinged; tail graduated, rectrices with stiffened shafts that lack barbs for distal 1-3 mm, chest-

nut; throat and malar area white, tinged creamy on lower throat; underparts streaked brown and buff, fading in intensity posteriorly, flanks dark reddish-brown, undertail-coverts rufescent brown with more reddish shaft streaks; iris brown; upper mandible black, pinkish at gape, lower mandible pinkish or flesh-coloured with black distal third; tarsus and toes brownish-grey. Sexes alike. Juvenile has supercilium indistinct or absent, back less reddish, throat feathers tipped grey-brown, less distinct streaks on underparts. Races described as differing from nominate as follows: *obscuradorsalis* darker overall, back with blackish edgings; *duidae*

slightly brighter above, supercilium and nape more chestnut than bay (i.e. less reddish), supercilium extending farther back; *mayri* (described from 4 specimens) as having back browner, less chestnut. **Voice.** Song 7-8 clear notes that ascend rapidly, "tee-tee-tee-teuu-teuu-tuutuu".

**Habitat.** Montane evergreen forest and elfin forest, often stunted, mossy and epiphyte-laden; also mossy second growth. At 1000-2500 m.

**Food and Feeding.** Arthropods. Forages usually singly or in pairs, and regularly in mixed-species flocks, in undergrowth. Hitches and creeps up trunks and branches. Gleans items from moss and epiphytes on vertical trunks, branches and vines, mainly within 1-6 m of ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tepuis EBA. Generally uncommon; possibly more common on Mt Roraima. Rather difficult to detect; possibly overlooked. Well protected in Canaima National Park, in Venezuela.

**Bibliography.** Barnett *et al.* (2002), Chapman (1931, 1939), Hilty (2003a), Lentino *et al.* (1998), Mayr & Phelps (1967, 1971), Meyer de Schauensee & Phelps (1978), Phelps (1977a), Pinto (1978), Renjifo *et al.* (1997), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rudge & Raikow (1992b), Sick (1993, 1997), Snyder (1966), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

## Genus MARGARORNIS Reichenbach, 1853

### 172. Ruddy Treerunner

#### *Margarornis rubiginosus*

**French:** Anabasis rousse **German:** Rostbrust-Stachelschwanz **Spanish:** Subepalo Rojizo  
**Other common names:** Ruddy Margarornis

**Taxonomy.** *Margarornis rubiginosa* Lawrence, 1865, San José, Costa Rica.

Anatomical data are consistent with the idea that this genus and *Premnornis*, *Premnoplex* and *Roraimia* are each others' closest relatives; various authors merge one or all of those into present genus. Two subspecies recognized.

#### Subspecies and Distribution.

*M. r. rubiginosus* Lawrence, 1865 - mountains of Costa Rica (S from S Cordillera Guanacaste) and W Panama (W Chiriquí).

*M. r. boultoni* Griscom, 1924 - mountains of C Panama (E Chiriquí, Veraguas).

**Descriptive notes.** 14-16 cm; 17-24 g. Very reddish-brown furnarid that forages much like a dendrocolaptid woodcreeper. Has supercilium and broad eyering buffy whitish, flecked brownish, giving "messy" look; rest of face dull rufescent brown; crown dull reddish-brown, vague narrow collar paler, less reddish; back to uppertail-coverts reddish-chestnut; wing-coverts reddish-chestnut, primary coverts dark brown, remiges dark fuscous with rufescent margins; tail graduated, rectrices with shafts stiffened basally and lacking barbs for distal 1-7 mm, producing "spiny" appearance, colour slightly paler than back; throat whitish,

becoming buffy white on lower border; breast dull rufescent brown with small pale buff V-shaped markings on upper breast, rounded darker buff spots with dark shaft streaks in centre of breast; belly dull rufescent brown with only hint of markings, flanks and undertail-coverts darker, more chestnut-brown; iris dark brown to brown; upper mandible black to brown, lower mandible pinkish-horn to pale pinkish-white; tarsus and toes greyish-olive to dull pinkish to greyish-brown (source of variation uncertain). Sexes alike. Juvenile has less distinct markings on breast, faint sooty margins of throat feathers. Race *boultoni* is generally brighter and more rufescent above and below, with pale spotting on breast reduced or absent. **Voice.** Call a thin, whistled "tsit", usually in rapid, irregular series; also gives metallic chirping notes and a trill.

**Habitat.** Montane evergreen forest at 1800-3000 m; locally down to 1200 m.

**Food and Feeding.** Analysis of stomach contents indicates diet consisting of (in terms of numbers of prey items) nearly 50% cockroach (Blattodea) egg cases, c. 10-15% each of Coleoptera, spiders and various flying insects, and smaller percentages of insect larvae, Orthoptera, Heteroptera and Dermaptera. Forages singly or in pairs, usually in mixed-species flocks, from understorey to canopy. Scansorial, regularly ascends limbs and trunks like a woodcreeper (Dendrocolaptidae); highly acrobatic, often foraging upside-down on undersides of branches. Gleans and probes for arthropods on branches and epiphytic vegetation, rarely also on dead leaves and bare branches. In one detailed study, over 95% of foraging manoeuvres were directed at epiphytic vegetation; of these, over 70% directed at bryophytes and fruticose lichens hanging from branches and c. 25% at bryophyte mats on branches.

**Breeding.** fledglings recorded in Mar-Jul. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common to common. Seems to be fairly adaptable; found in fragmented forest.

**Bibliography.** Anon. (1998a), Blake & Loiselle (2000), Cory & Hellmayr (1925), Delgado (1985), Hernández *et al.* (1995), Remsen (2003a), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Rudge & Raikow (1992b), Sillett

(1994), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Young *et al.* (1998).

## 173. Fulvous-dotted Treerunner

### *Margarornis stellatus*

**French:** Anabasis étoilée

**German:** Schmuckbrust-Stachelschwanz

**Spanish:** Subepalo Estrellado

**Other common names:** Star-chested Treerunner

**Taxonomy.** *Margarornis stellatus* P. L. Slater and Salvin, 1873, Province of Quito, Ecuador.

Anatomical data are consistent with the idea that this genus and *Premmornis*, *Premnoplex* and *Roraimia* are each others' closest relatives; various authors merge one or all of those into present genus. Monotypic.

**Distribution.** W & C Andes of Colombia (S from S Chocó, and in Antioquia) and W Ecuador (S to Chimborazo).

**Descriptive notes.** 13-14 cm; 21-22 g. Has broad but ill-defined supercilium dull rufescent brownish, auriculars dull reddish-brown, moustachial area more rufescent, crown dark reddish-brown, upperparts slightly paler; wing-coverts reddish-brown, primary coverts dark fuscous, remiges dark fuscous with dark rufescent edges; tail graduated, rectrices stiffened basally, lacking or almost lacking barbs for distal 1-6 mm, shafts of central pairs curving slightly downwards and inwards, colour dark reddish-brown; throat mostly whitish, upper breast strikingly patterned, a few rows of broad whitish spots outlined in blackish fol-

lowed by several rows of smaller elongate whitish spots more conspicuously outlined, set on rufous-brown background, spots becoming smaller and vanishing into rufous-brown on lower breast, belly, flanks and undertail-coverts; iris dark brown; upper mandible horn to whitish-horn with browner base and culmen, lower mandible horn; tarsus and toes greyish to brownish. Sexes alike. Juvenile undescribed. **Voice.** Undescribed; evidently seldom vocalizes.

**Habitat.** Montane evergreen forest heavily laden with moss and epiphytes, at 1200-2200 m; mostly at c. 1600 m in Ecuador.

**Food and Feeding.** Arthropods; Lepidoptera larvae 15 cm long recorded in diet. Forages singly or in pairs, usually in mixed-species flocks, from mid-storey to subcanopy. Hitches and clambers up or along branches; often forages upside-down acrobatically on undersides of branches, often uses tail for support. Gleans items from moss, epiphytes (including bromeliads) and bark, occasionally from leaves.

**Breeding.** Copulation observed in Feb. and adult carrying food in Apr. No further information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Chocó EBA. Rare to locally uncommon; rare to very rare and local in Ecuador, and recently listed as vulnerable in that country. Narrow elevational range means that global population is relatively small. Formerly regarded as reasonably common in Colombia, but much habitat within its range in that country has been lost; occurs in La Planada Nature Reserve. Restriction to lower montane cloudforest makes it highly vulnerable to deforestation; continuing rapid clearance of forest in Chocó region of Colombia a major threat.

**Bibliography.** Anon. (2003g), Chapman (1917), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Granizo (2002), Hilty & Brown (1983, 1986), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Stewie (2001).

## 174. Beautiful Treerunner

### *Margarornis bellulus*

**French:** Anabasis superbe

**German:** Nördlicher Perlstachelschwanz

**Spanish:** Subepalo Bonito

**Other common names:** Beautiful Margarornis

**Taxonomy.** *Margarornis bellulus* Nelson, 1912, Cerro Pirre, 4500 feet [c. 1370 m], near head of Río Limón, Darién, Panama.

Anatomical data are consistent with the idea that this genus and *Premmornis*, *Premnoplex* and *Roraimia* are each others' closest relatives; various authors merge one or all of those into present genus. Sister-species to *M. squamiger*, and very likely conspecific. Monotypic.

**Distribution.** Cerro Tacarcuna, Cerro Mali, Cerro Pirre, Altos de Quia and Serranía de Majé, in extreme E. Panama.

**Descriptive notes.** 14-15 cm; 18-19 g. Has buffish-white supercilium extending from supraloral region back to collar, dull reddish-brown postocular line, dark brown auriculars streaked whitish; dark brown moustachial area with small white spots, these broadening into stripes posteriorly and merging into collar; crown olive brown; upperparts and wing-coverts warm olive-brown, primary coverts darker, remiges dark fuscous with tawny-ochraceous margins; tail graduated, shafts stiffened and lacking barbs or nearly so for distal 3-7 mm, shafts curve downwards distally, dull reddish-brown; throat whitish; underparts rufescent

brown, upper breast with white to yellowish-white oval spots narrowly outlined dark brownish, these coalescing into irregular rows that extend into lower breast, then becoming more elongate and narrow on lower underparts; iris brown; upper mandible brownish, lower mandible pinkish; tarsus and toes grey. Differs from very similar *M. squamiger* (of race *perlatus*) mainly in having upperparts brown, rather than chestnut, duller tail, more ochraceous flight-feather edgings, more rufescent underparts, reduced spots on breast and belly. Sexes alike. Juvenile undescribed. **Voice.** A short trill has been heard.

**Habitat.** Montane evergreen forest, at 1350-1600 m; rarely to 900 m.

**Food and Feeding.** Arthropods. Usually seen in mixed-species flocks. Scansorial; also highly acrobatic, often foraging upside-down on undersides of branches. Gleans food items from branches and epiphytic vegetation, primarily in subcanopy.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Darién Highlands EBA. Appears to be rare within its tiny range. No data available on population size or trends. All areas where it occurs, except Serranía de Majé, are within legally protected Darién National Park; even so, some habitat within the park has nevertheless been cleared. Degradation and clearance of forest at lower elevations could extend to the higher levels occupied by this species; in such a case, the potential threat would undoubtedly become serious.

**Bibliography.** Angehr & Christian (2000), Anon. (1998a), Cory & Hellmayr (1925), Delgado (1985), Remsen (2003a), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore (1972).

## 175. Pearled Treerunner

### *Margarornis squamiger*

**French:** Anabasis perlée

**German:** Südlicher Perlstachelschwanz

**Spanish:** Subepalo Perlado

**Taxonomy.** *Anabates squamiger* d'Orbigny and Lafresnaye, 1838, Ayopaya, Cochabamba, Bolivia. Anatomical data are consistent with the idea that this genus and *Premmornis*, *Premnoplex* and *Roraimia* are each others' closest relatives; various authors merge one or all of those into present genus. Sister-species to *M. bellulus*, which very likely conspecific. Sight record in NW Argentina presumably referable to nominate race or, possibly, an undescribed race. Three subspecies recognized.

**Subspecies and Distribution.**

*M. s. perlatus* (Lesson, 1844) - Perijá Mts and Andes of W Venezuela (Trujillo, Mérida, Táchira), Colombia (all three ranges), Ecuador, and N Peru N of R Marañón (Piura, N Cajamarca).

*M. s. peruvianus* Cory, 1913 - Andes of N & C Peru S of R Marañón (from S Cajamarca and Amazonas S to Cuzco).

*M. s. squamiger* (d'Orbigny & Lafresnaye, 1838) - Andes of S Peru (Puno) and Bolivia (S to W Santa Cruz); sight record in NW Argentina (Salta).

**Descriptive notes.** 15-16 cm; 14-19 g. Strikingly patterned furnariid. Nominat race has sharply defined yellowish-buff supercilium extending from supraloral region back to collar, dull reddish-brown postocular line; auriculars dull yellowish-buff and dark brown; moustachial area dark brown with indistinct tiny spots, these broadening into stripes posteriorly and merging into collar; forehead dark brownish with dull pale rufous streaks, crown dark reddish-brown; collar dull rufescent brown, nearly completely covered by yellowish-buff elongated spots outlined in black, these fading and then disappearing in centre

of collar; back to uppertail-coverts bright reddish-brown; wing-coverts bright reddish-brown, primary coverts darker fuscous brown, remiges dark fuscous with rufescent margins; tail graduated, shafts stiffened and lacking barbs or nearly so for distal 3-7 mm, curving downwards distally, bright reddish-brown; throat bright buff-yellow, becoming more yellow along lower margin; upper breast a dense set of yellowish oval spots narrowly outlined dark brownish, these overlapping and coalescing into irregular rows that extend to lower breast, there becoming elongate, narrower and less distinct, exposing more of the dull rufescent ground colour of breast and belly; flanks darker rufescent with longer spots; undertail-coverts rufescent brown with few buff-yellowish streaks outlined in blackish; iris brown to dark brown; upper mandible black to grey, lower mandible whitish-horn to purplish-pink, sometimes with dark tip; tarsus and toes brownish-grey to dark brown. Sexes alike. Juvenile has more irregular pattern of spotting on breast, throat feathers tipped dusky, crown less uniform. Race *peruvianus* differs strongly from nominate in having olive-brown crown, much less yellowish spotting on underparts, supercilium not so deeply yellow, auriculars less rufous and more heavily streaked; *perlatus* is very similar to previous, but has supercilium whitish (not yellowish), slightly whiter spotting on underparts. **Voice.** Song a rapid series of high-pitched, thin "tick" notes, lasting c. 1-5 seconds. Call a single high-pitched "tick" or "tsit" note, like those in song; also short trill, "trrr-trrrr".

**Habitat.** Montane evergreen forest and elfin forest; also locally ranging into *Polylepsis* woodland, and second growth; most common in mossy, epiphyte-laden, stunted, high-elevation forest. Mostly 2500-3500 m; locally down to 1500 m and up to 3800 m.

**Food and Feeding.** Arthropods. Usually in pairs, less often singly or in groups of up to eight individuals; commonly in mixed-species flocks. Forages from mid-storey to canopy; mean foraging height in Bolivian high-elevation forest was 4-9 m above ground and 2-4 m from top of canopy. Scansorial, forages like a small woodcreeper (Dendrocolaptidae), hitches along mossy trunks and branches; highly acrobatic, often foraging upside-down on undersides of branches. Gleans items primarily from moss and epiphytic vegetation, less often bark, and occasionally from dead leaves, on horizontal or vertical branches, mostly 3-15 cm diameter.

**Breeding.** Fledglings seen in Jun in Venezuela, May in C Colombia, Jul in C Peru, and Mar and Dec in C Bolivia. Presumably monogamous. Nest a ball of moss with side entrance, placed under a limb or rock. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. Occurs in a number of protected areas, including Sierra Nevada and Guarumacal National parks, in Venezuela, Munchique National Park, in Colombia, and Podocarpus National Park, in Ecuador; rather common in Machu Picchu Historical Sanctuary, in Peru. Tolerates at least mild forest fragmentation and disturbance.

**Bibliography.** Alonso *et al.* (2001), Cory & Hellmayr (1925), Cuervo *et al.* (2003), Di Giacomo *et al.* (1995), Fjeldså & Krabbe (1990), Graves (1985), Hilty (2003a), Hilty & Brown (1983, 1986), Mayr & Phelps (1967), Mazar Barnett & Pearman (2001), Olivares (1969), Pacheco *et al.* (1996a), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Pearman (1994c), Peters & Griswold (1943), Poulsen (1996), Remsen (1985, 2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rudge & Raikow (1992b), Salaman (1994), Salaman *et al.* (1999), Stotz *et al.* (1996), Vuilleumier & Ewert (1978), Willis & Schuchmann (1993), Zimmer (1930, 1934c).

# Genus *PSEUDOSEISURA* Reichenbach, 1853

## 176. Grey-crested Cachalote

### *Pseudoseisura unirufa*

**French:** Cacholote uni **German:** Hellbrauner Cachalote **Spanish:** Cacholote Crestigris  
**Other common names:** Rufous/Rufous-breasted Cachalote (when treated as conspecific with *P. cristata*)

**Taxonomy.** *Anabates unirufus* d'Orbigny and Lafresnaye, 1838, Moxos (= Beni), Bolivia. Genus has no obvious close relatives within the family. Present species forms a superspecies with *P. cristata*; formerly treated as conspecific, but differs ecologically and vocally (important differences in vocalizations demonstrated by playback experiments), and possibly also in social system and nest architecture. Despite the geographical isolation of the two populations of the present species, there are no evident plumage differences that would warrant the naming of subspecies. Monotypic.

**Distribution.** NC & E Bolivia (Beni, extreme NW & SE Santa Cruz), SW Brazil (S Mato Grosso, Mato Grosso do Sul) and N Paraguay (Alto Paraguay).

**Descriptive notes.** 20-21 cm; 42-57 g. Large, rather uniformly coloured furnariid with crest. Has rather uniform bright reddish-rufous face; crown reddish-rufous, feathers elongated to form slight crest, some feathers with dull greyish tips and margins; upperparts and wings bright reddish-rufous, dark fuscous tips of remiges; tail nearly square, outer pair of rectrices c. 2 cm shorter than rest, shafts of all without barbs for distal 2-3 mm, bright reddish-rufous; underparts almost uniform bright reddish-rufous, slightly paler than back; centre of throat slightly different shade, more orange-tinged; iris yellow to buff-yellow; bill

blue-grey to grey, sometimes darker along culmen, usually paler on lower mandible; tarsus and toes olive to greenish-grey. Differs from extremely similar *P. cristata* in darker plumage coloration, significantly shorter bill (no overlap in measurements). Sexes alike. Juvenile has shorter crest, is less uniform in colour. **VOICE.** Song usually given as duet that lasts c. 6 seconds, presumed male 4-10 evenly spaced notes followed by accelerating series that becomes a rattle, with overall descending, bouncing-ball pattern (pitch slightly lower than that of *P. cristata*), presumed female a series of well-spaced "chep" notes (faster than *P. cristata* series); presumed male also gives chatter c. 1-5 seconds long, often between duet bouts. Call a single "chuk".

**Habitat.** Gallery forest, seasonally flooded savannas, often near marshes; regularly near human habitations. At 300-500 m.

**Food and Feeding.** Little known. Mostly arthropods; recorded items include fruit, and also probably fruit seeds. Usually in pairs. Mainly terrestrial; apparently gleans, probes, and digs for arthropods primarily on ground.

**Breeding.** Season presumably during austral spring-summer. Presumably monogamous. Nest an oblong mass, c. 60 × 30 × 30 cm, made of twigs and small branches, some as long as 50-60 cm, large feathers, snail shells, crab carapaces, and bones incorporated into exterior, entrance at bottom, interior tunnel leads upwards and enters spherical inner chamber from above, chamber c. 20 cm in diameter, lined with bark and bits of snakeskin; placed 4-5 m up in tree. No further information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common around ranch houses and other human habitations. Not particularly well known.

**Bibliography.** Cory & Hellmayr (1925), Hayes (1995), Naumburg (1930), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Tudor (1994), Short (1975), Stotz *et al.* (1996), Zimmer & Whittaker (2000).

## 177. Caatinga Cachalote

### *Pseudoseisura cristata*

**French:** Cacholote roux **German:** Zimbrauner Cachalote **Spanish:** Cacholote de la Caatinga  
**Other common names:** Rufous/Rufous-breasted Cachalote (when treated as conspecific with *P. unirufa*)

**Taxonomy.** *Anabates cristatus* Spix, 1824, Malhada, Rio São Francisco, Bahia, Brazil. Genus has no obvious close relatives within the family. Present species forms a superspecies with *P. unirufa*; formerly treated as conspecific, but differs ecologically and vocally (important differences in vocalizations demonstrated by playback experiments), and possibly also in social system and nest architecture. Monotypic.

**Distribution.** E Brazil (E Maranhão, Paraíba and Pernambuco S to C Minas Gerais).

**Descriptive notes.** 26 cm. Large, crested furnariid. Plumage is rather uniform bright reddish-rufous, paler and brighter below; crest feathers tipped and edged greyish, remiges tipped fuscous; tail nearly square, distal 2-3 mm of shafts lacking barbs; iris yellow; colours of bill and legs undocumented. Differs from extremely similar *P. unirufa* in paler plumage coloration, significantly longer bill (no overlap in measurements). Sexes alike. Juvenile has shorter crest, is less uniform in colour, with variable amounts of dusky streaking or barring on face and underparts, also bluish-grey iris. **VOICE.** Song usually given as duet

that lasts c. 7 seconds, presumed male 4-10 evenly spaced notes followed by accelerating series that becomes a rattle, with overall descending, bouncing-ball pattern (slightly higher-pitched than that of *P. unirufa*), presumed female a series of 15-35 well-spaced buzzy "zjeep" notes (slower and more strident than that of *P. unirufa*); presumed male also gives chatter that lasts c. 2 seconds, often between duet bouts. Call a single "chuk".

**Habitat.** Tropical deciduous forest; *caatinga* woodland and scrub, especially where overgrazed; common around human habitations in rural areas. At 50-500 m.

**Food and Feeding.** Recorded dietary items are Lepidoptera, Coleoptera, and vegetable matter. Usually in pairs. Mostly terrestrial; evidently gleans, probes and digs for arthropods primarily on ground.

**Breeding.** Season not documented. Probably mainly monogamous, but some breeding units seem to contain 3-4 individuals in adult plumage, all of which feed nestlings. Locality data in some nest descriptions vague, and uncertain whether some of following detail applies to this species alone or also to *P. unirufa*: nest a large elongated mass 90-100 cm long, 50 cm wide, of usually thorny sticks, some as large as 60 cm long and 1 cm in diameter, with large feathers, bone fragments and snail shells often incorporated, tunnel leading from entrance hole near upper end to spherical inner chamber c. 20 cm in diameter, lined with pieces of bark and snake skin; placed in fork of tree or on telephone pole. Clutch size not documented; single juveniles, presumably from previous brood, may remain with adults during subsequent nesting and may help with nest-building.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common, especially where *caatinga* severely degraded or overgrazed. Density often rather high; pairs typically separated from nearest neighbour by c. 300-400 m. Occurs in several protected areas, e.g. Cavernas do Peruaçu National Park. Has extended its range locally where forest has been cleared.

**Bibliography.** Azevedo (1989), Cory & Hellmayr (1925), Kirwan *et al.* (2001), do Nascimento *et al.* (2000), Parrini *et al.* (1999), Pinto (1978), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993, 1997), Stotz *et al.* (1996), Tubelis & Tomás (1999), Willis & Oniki (1990, 1991), Zimmer & Whittaker (2000).

## 178. Brown Cachalote

### *Pseudoseisura lophotes*

**French:** Cacholote brun **German:** Dunkelbrauner Cachalote **Spanish:** Cacholote Castaño

**Taxonomy.** *Homorus lophotes* Reichenbach, 1853, Guanacos, 700 m, c. 32 km ESE of Cabezas, Cordillera, Santa Cruz, Bolivia.

Genus has no obvious close relatives within the family. Plumage similarities suggest that this species is most closely related to *P. unirufa* and *P. cristata*. Two subspecies recognized.

**Subspecies and Distribution.**

*P. l. lophotes* (Reichenbach, 1853) - S Bolivia (S Santa Cruz, E Tarija) and W Paraguay.

*P. l. argentina* Parkes, 1960 - N & C Argentina (Catamarca, Santiago del Estero and Corrientes S to Mendoza, La Pampa and Buenos Aires), extreme SE Brazil (W Rio Grande do Sul) and Uruguay.

**Descriptive notes.** 24-26 cm; 63-79 g. One of the largest furnariids, somewhat resembling a jay (Corvidae). Has rather uniform dull dark rufous face; forehead dull dark reddish-brown; crown darker brown with darker feather margins, producing slightly streaked look, feathers elongated to form crest, hindcrown bright rufous (covered by crest feathers when flattened); upper back and vague collar rufous, rest of back duller with some greyish feather edges, rump bright rufous, uppertail-coverts slightly darker; wing-coverts dull dark rufous-brown with some paler tips, remiges dark fuscous brown with narrow pale brownish margins; tail

slightly rounded, shafts stiffened basally and nearly lacking barbs at tips, dull dark rufous; throat bright cinnamon-rufous, blending to duller darker breast with increasingly conspicuous paler tips of feathers posteriorly, this pattern extending into belly and flanks, producing "frosted" look; lower belly, flanks and undertail-coverts more rufescent, longest undertail-coverts with broad pale tips; iris yellow to buff-yellow; upper mandible usually black with grey base, lower mandible light grey basally, blackish distally; tarsus and toes greyish-olive to dull greenish. Sexes alike. Juvenile has shorter crest, lightly mottled breast and belly, dull greenish iris. Race *argentina* described as darker throughout, with anterior crest feathers less grey-brown, more rufous, and narrower. **VOICE.** Song, usually as duet, a long, loud series of variably cacophonous, grating, coarse notes that gradually fades towards end, can last at least 15 seconds; call "krok".

**Habitat.** Tropical deciduous forest, gallery forest edge, second-growth scrub; Chaco woodland and scrub, *monte* and *espinillo* (*Prosopis-Acacia*) woodland; urban parks and gardens. From near sea-level to 900 m.

**Food and Feeding.** Reported dietary items are Coleoptera (including families Curculionidae, Scarabaeidae, Chrysomelidae, Carabidae), larval insects, large ants, also eggs of other birds (including domestic chickens), seeds, some fruit. Forages usually in pairs or in small single-species flocks. Gleans, probes and digs for arthropods in ground and leaf litter; flakes dung to search for arthropods underneath; occasionally hammers and pulls bark and leaf buds.

**Breeding.** Season during austral spring-summer; eggs from late Sept to Feb, mean initiation date in W Argentina 19th Nov. Monogamous; probably pairs for life. Nest a large mass c. 50-150 cm long and 45-90 cm wide, weight 2-5.5 kg, main axis horizontal or diagonal, made of sticks (some up to 75 cm long, to 1 cm in diameter), external lateral entrance tube c. 30-40 cm long supported by horizontal branch, long feathers often incorporated into outside of nest, inner chamber 20-25 cm in diameter, often no lining, occasionally a few bits of plant material, small sticks or dung; placed 4-6 m above ground near crown of small tree (especially *Prosopis*), often isolated, with branches of tree incorporated into nest; frequently placed on previous years' nests. Clutch 2-4 eggs, mean 2.6; incubation by both adults, period 18-20 days; both also feed chicks, nestling period 18-23 days; young remain in parental territory for 5-13 months, but not nest helpers. Success: 59% of eggs produce fledglings, with mean of 1-5 fledglings per clutch; last-hatched nestlings in broods of three usually die, as do all in broods of four; older pairs have significantly higher reproductive success; nest predation, mainly by white-eared opossum (*Didelphis albiventris*), main source of mortality.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout range. Occurs in several protected areas, e.g. Chancani Natural Reserve, in Argentina.

**Bibliography.** Aravena (1928), Belton (1984), Bodrati *et al.* (2001), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuervo (1985), Eberhard (1996), Fraga & Narosky (1985), Friedmann (1927), Hayes (1995), Kratter *et al.* (1993), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Navas & Bó (1987), Norez, A.I. (1995), Norez, A.I. & Norez, M. (1994a, 1994b), Norez, M. *et al.* (1983), Ochoa (1971), Olog (1963a), Parkes (1960), Partridge (1953), de la Peña (1987, 1988, 1996), Pinto (1978), Remsen & Traylor (1989), Ridgely & Tudor (1994), Rodríguez (1918), Serié & Smyth (1923), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Wetmore (1926), Zotta (1940).

## 179. White-throated Cachalote

### *Pseudoseisura gutturalis*

**French:** Cachalote à gorge blanche **German:** Weißkehlcachalote **Spanish:** Cachalote Pardo

**Taxonomy.** *Anabates gutturalis* d'Orbigny and Lafresnaye, 1838, mouth of Río Negro, Patagonia, Argentina.

Genus has no obvious close relatives within the family. Geographical boundary between race *ochroleuca* and nominate controversial; thorough analysis required. Two subspecies recognized.

#### **Subspecies and Distribution.**

*P. g. ochroleuca* Olog, 1959 - Andean foothills and valleys in N & C Argentina (W Salta S to San Juan and La Rioja).

*P. g. gutturalis* (d'Orbigny & Lafresnaye, 1838) - lowlands and foothills of C Argentina (Mendoza, La Pampa and S Buenos Aires S to NE Santa Cruz).

**Descriptive notes.** 22-23 cm; 63-79 g. Large, dull furnariid with conspicuous white throat. Has white eyering, supraloral area and lores; rest of face, crown and upperparts nearly uniform dark dull brownish-grey; crown feathers slightly elongated; wings much like upperparts, coverts and remiges with slightly paler edges; tail slightly rounded, shafts slightly stiffened, lack or almost lack barbs for distal 1-4 mm, dark fuscous grey, slightly paler on outer webs; chin and most of throat white, sharply demarcated from malar area, centre of lower throat blackish with some paler grey feather tips; breast and belly dull brownish-grey, paler than back, with many feathers tipped greyish-white, producing "frosted" look, vent and undertail-coverts slightly paler; iris yellow to creamy buff or dark brown; upper mandible dark grey, lower mandible pale bluish with dark grey tip; tarsus and toes grey. Sexes alike. Juvenile has lightly mottled or barred breast and belly. Race *ochroleuca* was described as generally paler and sandier in colour throughout. **Voice.** Song perhaps the loudest in family, reportedly audible at nearly 2 km, cacophonous explosion of variable, harsh, raucous notes, often given as duet.

**Habitat.** Arid lowland scrub, including areas with sparse bushes (e.g. *Schinopsis marginata*) in generally barren areas, both in lowlands and in montane valleys; *Prosopis* woodland favoured in N portion of range. From sea-level to 2900 m.

**Food and Feeding.** Arthropods. Forages usually in pairs, but also frequently in small groups (possibly family parties). Mostly terrestrial. Gleans, probes and digs for arthropods on ground; occasionally digs into cactus stems.

**Breeding.** Season during austral spring-summer; eggs in Nov and Feb, and nestlings in Nov-Dec. Presumably monogamous. Nest a roughly spherical mass c. 40-120 cm long, 40-50 cm in diameter, main axis horizontal, structure strong enough to support a human standing on it without being damaged; of interwoven, often thorny sticks, entrance tube 35-45 cm long protruding from upper side near top and resting on horizontal branch, inner chamber 25-30 cm in diameter, lined with small twigs and grass; placed 1-3 m up in bush; new nest built each year but favoured locations reused, so that nests may accumulate over years. Clutch 3-5 eggs; young may remain with adults for up to 1 year, perhaps as nest helpers.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Evidently tolerant of fairly extensive anthropogenic habitat disturbance.

**Bibliography.** Anon. (2003d), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1977), Cory & Hellmayr (1925), Fraga & Narosky (1985), Griscom (1924), Hudson (1920), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olog (1958, 1959b, 1963a), de la Peña (1987, 1988), Ridgely & Tudor (1994), Salvador (1990), Stotz *et al.* (1996), Vuilleumier (1980a), Wetmore (1926), Zapata (1967).

PLATE 25

## Reichenbach, 1853

*Pseudocolaptes lawrencii*

**French:** Anabate chamois

**Spanish:** Trepamusgos Barbablanca Panameño

**German:** Fahlwangen-Astspäher

**Other common names:** Lawrence's Tuftedcheek; Pacific Tuftedcheek (*johnsoni*)

**Taxonomy.** *Pseudocolaptes lawrencii* Ridgway, 1878, La Palma and Navarro, 3500-5000 feet [c. 1070-1520 m], Costa Rica.

Genus has no obvious close relatives; placement near *Berlepschia* based on bill shape and other morphological characters associated with climbing and probing, all possibly due to convergence; somewhat similar in general facial pattern and distinctive malar tufts to some *Cinclodes*, traditionally assumed to be distantly related. Forms a superspecies with *P. boissonneaultii* and sometimes treated, with some justification, as conspecific: in plumage colour, present species and race *auritus* of that species are in many ways more similar to each other than either is to nominate race of latter; in addition, verbal descriptions of voice equivocal, and formal comparison of sonagrams may provide data for re-evaluation of taxonomy. Race *johnsoni* considered a separate species by some authors, but evidence for this marginal, based mainly on its occurrence at lower elevation (a characteristic of Andean birds of W Colombia), minor plumage features, and near-parapatry with nominate in elevational distribution. Proposed race *panamensis*, described from single specimen from W Panama, considered not diagnosable, as characters (more olivaceous back with paler streaks, browner flanks) within range of variation of nominate. Two subspecies recognized.

### Subspecies and Distribution

*P. l. lawrencii* Ridgway, 1878 - mountains of Costa Rica S to C Panama (E to E Veraguas).

*P. l. johnsoni* Lönnberg & Rendahl, 1922 - W Andes of Colombia (S from Antioquia) and W Ecuador (S to El Oro).

**Descriptive notes.** 20–21 cm; 45–58 g. Large, richly coloured, strongly patterned furnarid with conspicuous pale tawny tuft at side of neck. Nominate race has buff-whitish supercilium, blackish-brown lores and auriculars, supraloral area grizzled dull buff; malar area to side of neck pale golden tawny, feathers flaring into neck to form conspicuous tuft, crown blackish-brown with dense pattern of fine buff streaks; hindcollar of broad pale buff streaks on blackish-brown background, fading into upper back, rest of back rufescent brown with faint blackish scalloping; rump and uppertail-coverts bright chestnut-rufous; wings mostly

blackish-brown, coverts tipped pale rufous and ochraceous buff; tail graduated, shafts stiffened basally, pointed at tips, colour as rump; throat whitish with golden-tawny wash, trace of blackish-brown flecking along lower border and malar; breast a mix of dark dull brown and pale buff forming pattern of broad blurred streaks, darkest at side, fading posteriorly; belly dull tawny-buff with some faint, irregular mottling, flanks rufescent brown, undertail-coverts ochraceous to cinnamon; iris dark brown to brown; upper mandible black to dark brown, lower mandible variable, usually paler with darker area in centre; tarsus and toes olive-green to yellowish-olive, possibly sometimes more pinkish-grey. Sexes alike in plumage, but female has significantly longer bill than male. Juvenile has nearly solid blackish-brown crown, blackish-brown scalloping on throat and breast, more rufescent flanks and belly, substantially shorter bill. Race *johnsoni* is more rufous above and below, and more heavily scalloped below, extending to belly, with darker markings. VOICE. Song (in Costa Rica) a series of sharp "wit" notes followed by clear trill that ends with several distinct louder notes; also described as 1-2 clear introductory notes followed by liquid, gurgling trill that ascends, then slows and descends, "peek, peek, prrrrrrrreeeee". Call a loud, metallic, ringing "sfink" or "pwik".

**Habitat.** Montane evergreen forest, usually open or at edge, often ranging into clearings with trees. At 1550-3000 m in Central America (nominate); mostly 900-1500 m, locally down to 700 m and up to 2000 m in Andes (*johnsoni*).

**Food and Feeding.** Mostly arthropods, occasionally small amphibians. Diet in Costa Rica consisted primarily of Dermaptera, cockroaches (Blattodea), Orthoptera, insect egg cases, spiders, and Coleoptera. Other recorded items are moths, Lepidoptera larvae, and salamanders (*Salamandra*). Forages singly or in pairs, often or in some cases usually in mixed-species flocks, from mid-storey to canopy. Primarily clambers along upper surfaces of branches and limbs. Epiphyte specialist. Probes for and gleans items from moss and epiphytes, occasionally dead leaves, and rummages noisily in clumps of debris; frequently uses tail for support; often nearly disappears into dense epiphytic growth or debris clumps.

**Breeding.** Season Jan-May, in Costa Rica, with eggs recorded in Apr and nestlings in May; nestlings in Apr and Jun in Colombia (*johnsoni*). Presumably monogamous. Nest of nominate c. 9 m above ground in natural cavity or old hole of woodpecker (Picidae), in decaying trunk, lined with bits of plant matter, especially brown tree-fern scales; nest of *johnsoni* also in old woodpecker hole in decaying trunk, 11.5 m above ground. Clutch 1 egg; at the only well-studied nest, of nominate, only one adult incubated and fed chick; at two nests of *johnsoni* both members of pair fed young; nestling period at least 29 days.

### Movements, Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in most of Costa Rica; rare in W Panama; uncommon to rare in Ecuador, where race *johnsoni* considered vulnerable. Occurs in a number of protected areas, e.g. Río Nambí Natural Reserve, in Colombia.

**Bibliography.** Blake & Loiselle (2000), Cory & Hellmayer (1925), Cuervo *et al.* (2003), Granizo (2002), Hilty (1997), Hilty & Brown (1986), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely

& Tudor (1994), Ridgway (1911), Robbins & Ridgely (1990), Salaman (1994), Sillett (1994), Sillett *et al.* (1997), Skutch (1969c), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Strewe (2001), Vaurie (1974), Wetmore (1972), Zimmer (1935b, 1936c).

*Pseudocolaptes boissonneautii*

**French:** Anabate de Boissonneau

**Spanish:** Trepamusgos Barbablanca Andino

**German:** Weißwangen-Astspäher

**Taxonomy.** *Anabates Boissonneautii* Lafresnaye, 1840, "Bogotá"

Genus has no obvious close relatives; placement near *Berlepschia* based on bill shape and other morphological characters associated with climbing and probing, all possibly due to convergence; somewhat similar in general facial pattern and distinctive malar tufts to some *Cinclodes*, traditionally assumed to be distantly related. Forms a superspecies with *P. lawrencii* and sometimes treated, with some justification, as conspecific; in plumage colour, race *auritus* and that species are in many ways more similar to each other than either is to nominate race of present species; in addition, verbal descriptions of voice equivocal, and formal comparison of sonagrams may provide data for re-evaluation of taxonomy. Proposed race *orientalis*, from Ecuador, is a synonym of *oberholseri*; *intermedius* possibly indistinguishable from latter, quantitative study needed. Proposed race *pallidus*, from NW Peru, described as paler below and having reduced back streaking, but these supposed characters do not distinguish it from nearby *medius*. In Peru, allocation of San Martin and La Libertad populations to *auritus* is tentative, and specimens from Ayacucho and Cuzco show signs of intermediacy in colour of malar tuft and rump between that race and *carabayae*; also, latter possibly shows trend towards increasing dark scalloping on belly and darker rump colour farther S, but larger samples needed. Eight subspecies recognized.

### Subspecies and Distribution

*P. b. meridae* Hartert & Goodson, 1917 - Perijá Mts and Andes of NW Venezuela (Trujillo, Mérida, Táchira) and NE Colombia (E Andes S to Bovacá).

*P. b. striaticeps* Hellmayr & Seilern, 1912 - coastal ranges of N Venezuela (Yaracuy, and Carabobo E to Miranda).

*P. b. boissonneautii* (Lafresnaye, 1840) - Andes of Colombia (W & C ranges, and E range S from Cundinamarca)

*P. b. oberholseri* Cory, 1919 - Andes of Ecuador (both slopes).

*P. b. intermedianus* Chapman, 1923 - Andes of NW Peru (Piura, NW Cajamarca).

*P. b. medius* Hellmayr, 1919 - N Peruvian Andes S of R Marañón (S Cajamarca, and Amazonas S to San Martín).

*P. b. auritus* (Tschudi, 1844) - Andes of C Peru (La Libertad S to N Puno).

*P. h. carabayae* J. T. Zimmer, 1936 - Andes from S Peru (S Puno) S to C Bolivia (E to W Santa Cruz).

**Descriptive notes.** 20–22 cm; 37–62 g. Large, strongly patterned furnarid with conspicuous pale tuft at neck side. Nominate race has buff whitish supercilium, blackish-brown lores and auriculars, supraloral area grizzled dull buff; malar area and side of neck pale golden tawny, feathers flaring into neck to form conspicuous tuft; malar area and side of neck almost pure white, feathers forming conspicuous tuft; crown blackish-brown with dense, fine buff streaks; hindneck and back blackish-brown with broad pale buff streaks, lower back rufescent brown, rump and uppertail-coverts brighter chestnut-rufous; wings mostly black-

ish-brown, coverts edged and tipped pale rufous, secondaries edged rufous at bases, tertials largely rufous; tail graduated, shafts stiffened basally, pointed at tips, bright rufous; throat white; breast pale golden buff, feathers margined dark brown, forming scaly pattern, fading posteriorly; rest of underparts rufescent, darkening posteriorly; iris brown to dark brown; upper mandible black, lower mandible greyish-white to silvery with blackish upper third; tarsus and toes grey to slate. Sexes alike, except that female has significantly longer bill. Juvenile has solid black crown, dense black scalloping on breast, darker belly and flanks almost entirely rich rufous, substantially shorter bill. Compared with nominate, race *striaticeps* has less scaling on breast, duller underparts, also described as having broader, darker crown streaks, deeper ochraceous and more pronounced supercilium, more cinnamon-coloured back with narrower spots lacking blackish margins; *meridae* has neck and breast feathers with little or no black fringing; *oberholseri* differs from nominate mainly in darker crown, heavier blackish fringing on neck and breast feathers; *intermedianus* is like previous, but evidently longer-billed, more heavily marked on back; *medius* differs from last two in having yellowish tinge on throat; *auritus* differs from previous only in having reduced sexual dimorphism, with female bill length reduced; *carabayae* differs from last in darker, blacker back, darker and more chestnut rump, malar tufts suffused with pale yellowish, flanks darker and browner (less rufescent), reduced sexual dimorphism in bill length, significantly smaller body size, perhaps also rump darker and belly more dark-scalloped towards S of range. VOICE. Song high-pitched for size of bird, 1-2 sharp "spik" notes followed by series of whistled tinkling "tsee" or "che" notes on same pitch, slightly accelerating, followed by dry, quavering trill, sometimes ending abruptly with distinct notes, "spik, spik, chechehechechechehechehechchch... dzzdzdzdzdzdzdzdzdz", can last up to 8 seconds. Contact call a loud, dry "chut" or "chink".

**Habitat.** Montane evergreen forest and elfin forest; mostly 1700–3200 m, locally down to 1450 m and up to 3500 m.

**Food and Feeding.** Recorded dietary items are Lepidoptera larvae and small frogs. Forages singly or in pairs, often or usually in mixed-species flocks, from mid-storey to canopy. In Bolivia high-elevation forest, mean foraging height was 8.5 m above ground and 4 m below top of canopy. Hitches along upper surfaces of horizontal and sloping branches, less frequently up vertical branches and trunks, mostly 5-20 cm in diameter. Epiphyte specialist. Probes for and gleans arthropods from bromeliads, moss and other epiphytic vegetation, occasionally also bark, dead leaves and green leaves; rummages noisily in debris caught in epiphytes, often using tail as a prop.

On following pages: 182. Point-tailed Palmcreeper (*Berlepschia rikeri*); 183. Scaly-throated Foliage-gleaner (*Anabacerthia variegaticeps*); 184. Montane Foliage-gleaner (*Anabacerthia striaticollis*); 185. White-browed Foliage-gleaner (*Anabacerthia amaurotis*); 186. Guttulated Foliage-gleaner (*Syndactyla guttulata*); 187. Lineated Foliage-gleaner (*Syndactyla subalaris*); 188. Buff-browed Foliage-gleaner (*Syndactyla rufosuperciliata*); 189. Rufous-necked Foliage-gleaner (*Syndactyla ruficollis*); 190. Peruvian Recurvebill (*Simoxenops ucayalae*); 191. Bolivian Recurvebill (*Simoxenops striatus*); 192. Chestnut-winged Hookbill (*Ancistrops strigilatus*); 193. Striped Woodhaunter (*Hylocisthes subulatus*).

dark brown; bill greyish-horn to olive-grey, sometimes darker along culmen, lower mandible sometimes paler; tarsus and toes olive to yellowish-brown. Sexes alike. Juvenile has darker crown, more prominent eyering and supercilium, is generally more rufous. Race *anxia* has eyering, postocular stripe, throat and breast more yellowish-buff, uppertail-coverts bright rufous like tail; *perijana* is paler, back more yellowish-brown, throat yellowish, underparts more yellowish-olive, less brown; *venezuelana* differs from previous in greyer crown and auriculars, browner back, bright rufous uppertail-coverts, whitish throat, more

greyish-brown breast and belly; *montana* is like nominate, but crown browner, contrasting less with back, back darker and more rufescent, tail darker, more chestnut, breast streaks more prominent, varies clinally, back redder in C Peru, specimens from Ayacucho more or less intermediate between this race and next; *yungae* is more reddish throughout, varies clinally, crown darker with faint dark spots (no streaks) and back darker red in Bolivia (Cochabamba) than in S Peru, specimens from La Paz intermediate. Voice. Song an accelerating, belaboured series of staccato, high-pitched, ticking, squeaky, dry "peck" or "chik" notes, roughly on same pitch, sometimes descending slightly at end, sometimes ending abruptly, duration c. 5 seconds. Call a high, squeaky, sharp "chit" or "chik"; also gives scratchy rattle.

**Habitat.** Montane evergreen forest; mostly 900-2300 m, locally to 2600 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks, from mid-storey to subcanopy. Clammers and hops along horizontal branches. Dead-leaf specialist. Gleans arthropods acrobatically from dead leaves, debris, epiphytes (including bromeliads), and mossy branches.

**Breeding.** Presumably monogamous. Two nests described, placed in broken off stump of *Bactris* palm or dead tree, lined with lichens and moss. Clutch 2 eggs. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. Occurs in several protected areas, including Henri Pittier and Guaramacal National Parks, in Venezuela; fairly common in Machu Picchu Historical Sanctuary, in Peru.

**Bibliography.** Chapman (1926), Cory & Hellmayr (1925), Edwards & Lea (1955), Fjeldså & Krabbe (1990), Graves (1985), Hilty (1997, 2003a), Hilty & Brown (1983, 1986), Meyer de Schauensee (1952), Miller (1963), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Phelps & Phelps (1952), Remsen (2003a), Remsen & Parker (1984), Remsen & Traylor (1989), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman (1994), Schulenberg (2002), Sillett *et al.* (1997), Slud (1964), Stotz *et al.* (1996), Todd & Carriker (1922b), Whitney *et al.* (1994), Zimmer (1935a).

## 185. White-browed Foliage-gleaner

### *Anabacerthia amaurotis*

**French:** Anabate bridé **German:** Rahmbrauen-Blattspäher **Spanish:** Ticotico Cejiblanco

**Taxonomy.** *Anabates amaurotis* Temminck, 1823, Ypanema, São Paulo, Brazil.

Genus sometimes merged into a broadly defined *Philydor*. This species suspected by some authors as being not particularly closely related to either *A. variegaticeps* or *A. striatocollis*. Monotypic.

**Distribution.** SE Brazil (S Espírito Santo S to Santa Catarina, also C Rio Grande do Sul) and NE Argentina (Misiones); also several sight records from SE Paraguay (Canendiyú, Alto Paraná, Caazapá).

**Descriptive notes.** 15-16 cm. Medium-sized furnariid with conspicuous supercilium, diagnostic black and white crown patch, wedge-shaped bill. Has broad, sharply defined buff-white supercilium behind eye (a hint of this extending in front to bill base), well-defined dark brown postocular band and faint loreal spot, rest of face light buff with faint flecking and streaking, indistinct brown moustachial streak; crown brown with a splash of broadly blackish-margined whitish-based feathers (bases usually concealed) in centre of posterior crown, blackish margins also on hindcrown feathers; narrow, almost complete

collar formed by pale buff spotting that extends across neck side; back rich medium brown, becoming slightly paler on rump, rufous uppertail-coverts; wings rich medium brown, darker brown primary coverts; tail nearly square, shafts slightly stiffened basally, slightly pointed tips, distal 1 mm or so lacking barbs (possibly through wear), rufous; throat creamy whitish, blending to light brown breast with broad, blurred pale buff streaking, this fading posteriorly, belly light brown, flanks and undertail-coverts slightly darker, tinged rufescent; iris dark brown; bill pale horn with some pale grey, dusky base of culmen; tarsus and toes brownish-flesh to dull flesh-tinged olive. Sexes alike. Juvenile undescribed. Voice. Song a series of rough, staccato notes c. 2 seconds long, followed by 3-4 loud notes, "t-t-t-t-t-t-t-t", jrèék, jrèék, jrèék"; in Rio Grande do Sul (Brazil), terminal notes apparently missing. Contact call a high-pitched, insect-like "tsip" or "pseek" in slow series.

**Habitat.** Montane evergreen forest and tall second growth in heart of range in SE Brazil; also in hilly areas in lowlands in W and in nearby Argentina, apparently also E Paraguay. Mainly 600-1500 m, locally down to near sea-level.

**Food and Feeding.** Arthropods; Lepidoptera larvae recorded. Forages usually in mixed-species flocks, mainly in understorey, occasionally to subcanopy and ground. Acrobatically probes, pulls, gleans and pecks dead leaves, debris and branches; occasionally makes short sally-strikes.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Rare to locally fairly common; definitely rare and local in low-elevation S portion of range. In Brazil, fairly common in Serra dos Órgãos National Park, rare in Itatiaia National Park; reported in San Rafael National Park, in Paraguay. Has relatively small range in which extensive deforestation has dramatically reduced its habitat. Agricultural expansion and urbanisation are major current threats.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Belton (1984), Canevari *et al.* (1991), Chebez *et al.* (1999), Cordeiro (2001), Cory & Hellmayr (1925), Lowen, Bartrina, Brooks *et al.* (1996), Madroño, Clay *et al.*

## Genus SYNDACTYLA Reichenbach, 1853

### 186. Guttulated Foliage-gleaner

#### *Syndactyla guttulata*

**French:** Anabate à gouttelettes **German:** Zimtbrauen-Blattspäher **Spanish:** Ticotico Goteado  
**Other common names:** Guttulated Leaf-gleaner

**Taxonomy.** *Anabazenops guttulatus* P. L. Slater, 1858, near Caracas, Venezuela.

Genus sometimes merged into *Philydor*; plumage, foraging behaviour and voice have suggested to some authors that it may be more closely related to *Thripadectes* than currently indicated in linear sequences. This species forms a superspecies with *S. subalaris*. Identity of population in Sierra de San Luis (Falcón) uncertain, presumed to belong with nominate race. Two subspecies recognized.

**Subspecies and Distribution.**

*S. g. guttulata* (P. L. Slater, 1858) - N Venezuela, in C Falcón (Sierra de San Luis) and coastal mountains (Yaracuy, Carabobo E to Distrito Federal, S Aragua).

*S. g. pallida* J. T. Zimmer & Phelps, Sr., 1944 - mountains of NE Venezuela (NE Anzoátegui, Sucre, N Monagas).

**Descriptive notes.** 17-19 cm; 34-38 g. Dark and heavily streaked furnariid with laterally compressed wedge-shaped bill (more so than congeners). Has faint supercilium dull ochraceous, becoming paler posteriorly, auriculars dark brown with narrow buff streaks, rest of face dark brown with small buff to ochraceous spots; top of head dark rufescent brown, paler rusty spots on forehead, fine rusty streaks on crown; back dark rufescent brown with blackish-margined broad rusty to whitish-buff streaks, rump and uppertail-coverts reddish-chestnut, wings mostly dark rufescent brown; tail graduated, rectrices with blunt tips, red-

dish-chestnut; throat yellowish, feathers of lower throat margined dark brown; breast and belly dark brown with conspicuous buffy streaks, fading on lower belly, undertail-coverts more rufescent; iris dark brown; upper mandible mostly dark grey to blackish, lower mandible pale horn-grey with darker grey upper base and central line; tarsus and toes olive-grey. Sexes alike. Juvenile undescribed. Race *pallida* described as like nominate but feather margins of upperparts paler, rump and tail paler rufous. Voice. Song a harsh, accelerating "cjak, cjak, czak czak-zak-zak-za-za-za", sometimes followed by a few more notes at end; call a harsh, rough "chak".

**Habitat.** Montane evergreen forest and secondary forest; 900-2100 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, often in mixed-species flocks; occasionally follows army ants. In understorey, rarely to mid-storey, and mostly in dense undergrowth. Often hangs down acrobatically, and clings sideways on branches. Gleans and chisels arthropods from dead twigs, and branch tips, and flakes and pries bark and dead twigs; also gleans from dead leaves and bases of bromeliads.

**Breeding.** Presumably monogamous. A nest thought to have been of this species was in cavity in wall, filled with twigs, with entrance at bottom. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Caripae-Paria Region EBA and Cordillera de la Costa Central EBA. Uncommon to locally fairly common, and has small range. Occurs in Henri Pittier National Park.

**Bibliography.** Boesman (1998), Cory & Hellmayr (1925), Hilty (1999, 2003a), Renjifo *et al.* (1997), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Verea *et al.* (1999), Zimmer & Phelps (1944).

### 187. Lineated Foliage-gleaner

#### *Syndactyla subalaris*

**French:** Anabate vergeté **German:** Streifenblattspäher **Spanish:** Ticotico Rayado  
**Other common names:** Stripe-bellied Foliage-gleaner, Lineated Leaf-gleaner

**Taxonomy.** *Anabates subalaris* P. L. Slater, 1859, Pallatanga, Chimborazo, Ecuador.

Genus sometimes merged into *Philydor*; plumage, foraging behaviour and voice have suggested to some authors that it may be more closely related to *Thripadectes* than currently indicated in linear sequences. This species forms a superspecies with *S. guttulata*. Proposed race *colligata* from NW Peru said to have crown and back less fuscous brown (contrasting more with blackish collar) and chin darker yellow than *mentalis*, but description based on only 3 specimens, and characters mentioned are highly individually variable; proposed race *ruficrissa* from C Peru supposedly with back blacker, rump and uppertail-coverts more rufescent and throat patch more restricted, but these characters also highly variable and do not permit diagnosis of individual specimens (although lack of distinctive features rather surprising, given major biogeographical barrier separating this population from those of N Andes). Six subspecies recognized.

**Subspecies and Distribution.**

*S. s. lineata* (Lawrence, 1865) - mountains of Costa Rica and W Panama (E to Veraguas).

*S. s. tacarcunae* (Chapman, 1923) - cerros Mali, Pirre and Tacarcuna, in extreme E Panama and NW Colombia.

*S. s. subalaris* (P. L. Slater, 1859) - Andes of W Colombia (W range, W slope of C range) and W Ecuador (S to El Oro).

*S. s. striolata* (Todd, 1913) - E Andes in NW Venezuela (Lara, Barinas) and Colombia (Magdalena S to Meta and Huila, and Serranía San Lucas).

*S. s. olivacea* Phelps, Sr. & Phelps, Jr., 1956 - SW Táchira (Chiquito Valley), in W Venezuela.

*S. s. mentalis* (Taczanowski & Berlepsch, 1885) - E slope of Andes in Ecuador and Peru (S to Cuzco).

blurry brownish streaking; breast dark brown with conspicuous buff streaks, blending to slightly paler brown belly and flanks with narrower streaks that almost disappear posteriorly; undertail-coverts with broader, more ochraceous streaks; iris brown to dark brown; upper mandible dark brown to black, lower mandible variable, from greyish-horn to yellowish-grey to ivory, sometimes darker central area; tarsus and toes olive-green to greenish-grey. Sexes alike. Juvenile is brighter generally, crown blacker with narrow cinnamon streaks, back more reddish-brown, black malar stripe with dull white spots, chin speckled black, supercilium, neck and breast more ochraceous cinnamon, sides and flanks richer brown, undertail-coverts cinnamon-brown, also shorter bill. Race *lineata* is like nominate, but back slightly paler, more rufescent, throat more buffy yellow and heavily marked, underparts slightly more olivaceous with narrower, more sharply defined streaks; *tacarcumae* is like previous, but has darker, more olive-brown back, greyer underparts, paler and more yellowish throat, *striolata* is evidently like nominate, but crown slightly darker, less rufescent, and more conspicuously streaked buff, back streaks broader, wings less rufescent, throat paler and less buffy, streaks below broader and extend farther into belly; *olivacea* is the most olivaceous below, also differs from last in having back and crown darker, more blackish-brown; *mentalis* is like nominate but crown usually blacker, crown and nape with more conspicuous streaking, supercilium less distinct, throat darker and more buffy yellow, underparts more strongly streaked and slightly more rufescent. Voice. Song a fast, accelerating series of 6-10 dry, harsh, scratchy, nasal notes described as "djit", "anh" or "ki", sometimes ascending and then descending, sometimes accelerating and then decelerating, ending abruptly, "bzert, bzert, jzut, jzut-ji-ji-ji". Call described as a dry, very harsh "tzuk", "tcheck", "skanh", "jert" or "kr-rk", sometimes repeated.

**Habitat.** Montane evergreen forest, especially along streams and treefalls, where undergrowth particularly dense; mostly 1000-2300 m, locally down to 600 m.

**Food and Feeding.** Mostly arthropods, occasionally small vertebrates; reported dietary items are Coleoptera, Orthoptera including crickets (Gryllidae), cockroaches (Blattodea), spiders, also small frogs and lizards. Forages singly or in pairs, sometimes to usually in mixed-species flocks, from understorey to midstorey. Gleans and probes for items on dead leaves, moss, bark, debris, epiphytes and foliage, usually by climbing along large branches and vines; often hangs down to reach sides and undersides of branches.

**Breeding.** Fledgling found in Dec in NW Ecuador. Presumably monogamous. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout range. Occurs in several protected areas, e.g. La Planada Nature Reserve, in Colombia.

**Bibliography.** Anon. (1998a), Bond (1945), Chapman (1926), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Graves (1985), Hernández *et al.* (1995), Hilty (1997, 2003a), Hilty & Brown (1983, 1986), Miller (1963), Parker & Carr (1992), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Phelps & Phelps (1956), Powell (1980), Pratt (1992), Remsen (1981, 1984a, 1984b, 1985, 2003a), Remsen & Parker (1983, 1984), Ridgely & Tudor (1994), Ridgway (1909), Robbins *et al.* (1985), Salaman (1994), Salaman, Donegan & Cuervo (1999, 2002), Schulenberg *et al.* (2001), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Zimmer (1935a).

## 188. Buff-browed Foliage-gleaner

### *Syndactyla rufosuperciliata*

**French:** Anabate à sourcils fauves **German:** Ockerbrauen-Blattspäher **Spanish:** Ticotico Cejudo

**Taxonomy.** *Xenops rufosuperciliatus* Lafresnaye, 1832, Rio de Janeiro, Brazil.

Genus sometimes merged into *Philydor*; plumage, foraging behaviour and voice have suggested to some authors that it may be more closely related to *Thripadectes* than currently indicated in linear sequences. The taxon *S. mirandae*, described from C Brazil (Goias) and subsequently treated as a race of present species, is in fact a synonym of *Philydor dimidiatum*. Proposed race *squamiger*, described from SE Brazil (Paraná), considered a synonym of nominate race by subsequent authors; proposed race *similis*, from NW Peru, described as like *cabanisi* but more olivaceous (less rufescent) above, and paler and much less heavily marked below, but these differences not apparent in specimens from within a few km of type locality. Four subspecies recognized.

#### Subspecies and Distribution

*S. r. cabanisi* (Taczanowski, 1875) - Andes of S Ecuador (Cordillera del Cóndor, in Zamora-Chinchipe), Peru (Piura, Cajamarca and S from Amazonas) and W Bolivia (S to Cochabamba).

*S. r. oleaginea* (P. L. Slater, 1884) - Andes from C Bolivia (S from W Santa Cruz) S to NW Argentina (S to La Rioja).

*S. r. rufosuperciliata* (Lafresnaye, 1832) - SE Brazil (S Minas Gerais and S Espírito Santo S to Paraná).

*S. r. acrita* (Oberholser, 1901) - NC Paraguay and extreme SE Brazil (Santa Catarina, Rio Grande do Sul) S to NE Argentina (Chaco and Misiones S to NE Santa Fé and N Buenos Aires) and Uruguay.

**Descriptive notes.** 17-18 cm; 22-33 g. Nominative race has tawny-buff eyering contiguous with paler supercilium that extends, broken, posteriorly to nape, hint of supercilium in front of eye; rest of face brownish with irregular buff markings; crown dull olive-brown, hint of whitish shaft streaks on centre of rear crown, faint collar of pale spotting; back to uppartail-coverts olive-brown; wings mostly rich olivaceous brown; tail graduated, shafts slightly stiffened basally, slightly pointed tips, distal 1-2 mm without barbs (may vanish with wear), dull rufous; throat whitish, some feathers with narrow but distinct brownish tips;

breast buffy whitish, with olive-brownish feather margins producing scalloped look; belly olive-brownish with broad, blurred buffy-whitish streaks, fading posteriorly; flanks slightly darker, less streaked, undertail-coverts with broader streaks, tinged ochraceous; iris brown to dark brown; upper mandible brown to dark grey to black, lower mandible whitish to blue-grey; tarsus and toes olive to brownish-grey. Sexes alike. Juvenile described as spotted rather than streaked below. Race *acrita* is like nominate, but browner, more olivaceous (less rufescent) above, tail darker, more chestnut, underparts darker and more olivaceous, belly streaking more prominent, supercilium slightly paler; *oleaginea* differs from nominate in having brown of underparts more olivaceous, streaks below narrower and more elongated; *cabanisi* has crown darker, supercilium richer ochraceous, back slightly darker richer brown, uppartail-coverts suffused with chestnut, tail slightly darker, more chestnut, wings warmer brown with chestnut tinge on coverts and secondaries, throat more buff-tinged, brown of underparts darker, richer, more ochraceous, streaking more tawny-buff, juvenile described as having darker upperparts and darker feather margins below than adult, another (of "*similis*") as having paler, greyer upperparts, paler supercilium, more sharply defined feather margins below. Voice. Song a loud, fast, accelerating series, "kuh-kuh-kuh-kihikihikihikikikku", starting faintly and ascending, then louder and quavering or descending, variable in length, c. 1.5-2.5 seconds; at least superficially similar throughout range. Call described as "kssr", alarm as sharp "set" or "setet".

**Habitat.** In Andes, montane evergreen forest and second growth, often with *Chusquea* bamboo; mostly 1300-2500 m, locally to 1000 m in C Bolivia. In SE part of range (nominate race, *acrita*), tropical lowland evergreen forest, gallery forest and secondary forest, to 2000 m.

**Food and Feeding.** Arthropods; tent caterpillars recorded. Forages singly or in pairs, sometimes (Andes) to possibly usually (lowlands) in mixed-species flocks; primarily in undergrowth, but ranges to subcanopy and occasionally even down to ground. Gleans items from branches, dead leaves and other debris, and epiphytes; occasionally hammers branches.

**Breeding.** Eggs in Nov in NW Argentina, nestlings in Nov in SE Brazil and fledgling in Aug in S Peru. Presumably monogamous. Three nest-sites documented, in hole 5 m up in rotting branch, 2-7 m up in hole in wall of building, and c. 2 m up in vertical pipe 11 cm in diameter; also reported to use old hole of woodpecker (Picidae); one nest described, a shallow cup made of small twigs. Clutch 2-4 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in most of its range; rare in Paraguay and N Peru. Occurs in numerous protected areas, including Ybicui National Park, in Paraguay, Aparados da Serra National Park and Serra do Mar State Park, in Brazil, and Calilegua National Park and Urugua-í and La Araucaria Provincial Parks, in Argentina.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Belton (1984), Bond (1945), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1927), Chebez *et al.* (1999), Cory & Hellmayr (1925), Cuello (1985), Di Giacomo & López (1998), Ferreira de Vasconcelos & Melo-Júnior (2001), Fiora (1933), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Fraga & Narosky (1985), Goerck (1999a), Graves (1985), Hayes (1995), Hayes & Scharf (1995a), Herzog *et al.* (1997), Krabbe & Sornoza (1994), Madroño, Robbins & Zyskowski (1997), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Norez & Cerana (1990), Novaes (1953), Olrog (1963a), Parker & Goerck (1997), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Pearman (1994c), de la Peña (1988), Pereyra (1938), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salvador (1988, 1990), Schulenberg *et al.* (2001), Scott & Brooke (1985), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Taczanowski (1884), Wetmore (1926), Willis (1992b), Zimmer (1935a).

## 189. Rufous-necked Foliage-gleaner

### *Syndactyla ruficollis*

**French:** Anabate à cou roux **German:** Rosthals-Baumspäher **Spanish:** Ticotico Cuellirrufo

**Taxonomy.** *Anabazenops ruficollis* Taczanowski, 1884, Paucal (= Nanchu), Cajamarca, Peru.

Genus sometimes merged into *Philydor*; plumage, foraging behaviour and voice have suggested to some authors that it may be more closely related to *Thripadectes* than is indicated in linear sequences. Tentative inclusion of this species in current genus based largely on vocal characteristics; formerly placed in *Automolus*, but voice and plumage unlike any species in that genus. Proposed race *celicae*, from SW Ecuador, described as brighter, paler and more ochraceous, especially on upperparts, and has ochraceous supercilium and broader breast streaks; these features, however, can be found throughout species' range and may be due to differences in age and plumage wear. Monotypic.

**Distribution.** Coastal hills and W slope of Andes in SW Ecuador (Loja) and NW Peru (Tumbes S to Lambayeque).

**Descriptive notes.** 18-19 cm; 29-39 g. Fairly large furnarid; unlike in others of genus, bill not obviously wedge-shaped. Conspicuous orange-rufous supercilium extends posteriorly to nape, faintly in front of bill base; postocular band dark brownish, auriculars and lores grizzled greyish, dark brownish and buff, moustachial area orange-rufous to ochraceous buff, often scaled dark brown; crown dark rufescent brown; indistinct collar of vague rufous streaking and spotting; back rich rusty brown, rump redder, uppartail-coverts bright chestnut; wings mainly rich rusty brown, slightly darker primary coverts; tail slightly graduated,

shafts slightly stiffened basally, slightly pointed tips, distal 1 mm of shaft without barbs (possibly worn off), dark chestnut; chin pale tawny-ochraceous, blending to more intensely ochraceous lower throat; olivaceous brown breast with broad, blurry pale rufescent buff streaking, this fading posteriorly; belly medium olivaceous brown, flanks darker, tinged rufescent, undertail-coverts dark rufous; iris brown; upper mandible dark brown to blackish, lower mandible pale brownish or pale greyish; tarsus and toes greyish-olive or olive-greenish. Sexes alike. Juvenile is duller throughout, crown more dusky, less brownish, some dark brown edging on throat feathers. Voice. Song a harsh, nasal "chick, chick, che-che, ttrrrrr", 2-3 seconds long, final note downward-inflected, pattern similar to that of *S. rufosuperciliata* song; contact call described as sharp, nasal "ank" or "chech".

**Habitat.** Montane evergreen forest and tropical deciduous forest; often in bamboo, shaded ravines, along streams; also second growth. Mainly 1000-2625 m, occasionally down to 400 m and up to 2900 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, often in mixed-species flocks; during dry season also in small groups and almost always in mixed flocks. Mostly from understorey to mid-

storey. Hitches along horizontal limbs and trunks. Gleans and probes for arthropods in moss, bases of bromeliads, sheaths on bamboo stems, ferns, and debris; occasionally searches leaf litter on ground. **Breeding.** Breeds probably during Jan-May wet season. Nest not described. No further information. **Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Tumbesian Region EBA. Common in El Tundo Nature Reserve, in S Loja, Ecuador; uncommon to fairly common in Tumbes National Reserve, in Peru, in which country is present also in protected Chĩnama Forest (Lambayeque). Population estimated at more than 10,000 individuals; declining strongly as a result of habitat destruction. Much forest within its small range already lost, and clearance of low-land forest continuing at fast rate; habitat loss at higher elevations less severe, but still a threat. Evidently tolerant of at least moderate forest degradation.

**Bibliography.** Best & Clarke (1991), Best & Kessler (1995), Best, Clarke *et al.* (1993), Bloch *et al.* (1991), Chapman (1921a, 1926), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cook (1996), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Parker, Parker & Plenge (1982), Parker, Schulenberg, Graves & Braun (1985), Parker, Schulenberg, Kessler & Wust (1995), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sillett *et al.* (1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Walker (2002), Wege & Long (1995), Wiedenfeld *et al.* (1985), Williams & Tobias (1994), Zimmer (1935a).

## Genus *SIMOXENOPS* Chapman, 1937

### 190. Peruvian Recurvebill

#### *Simoxenops ucayalae*

**French:** Anabate à bec retroussé **Spanish:** Ticotico Picolezna Peruano  
**German:** Starkschnabel-Blattsphäher  
**Other common names:** Peruvian Foliage-gleaner

**Taxonomy.** *Anachilus ucayalae* Chapman, 1928, Lagarto, upper Río Ucayali, Peru. Genus merged by some authors into a broad *Philydor*; close relationship to *Syndactyla* suggested by vocalizations and general behaviour. May form a superspecies with *S. striatus*. Described taxon *Megaxenops ferruginea* is a synonym of present species. Monotypic.

**Distribution.** Amazonian SE Peru (S Ucayali, Cuzco, Madre de Dios) and N Bolivia (W Pando); also S Amazonian Brazil (Acre, N Mato Grosso, Pará).

**Descriptive notes.** 19–20 cm; 39–55 g. Fairly large, dark rufous furnariid with conspicuously heavy, wedge-shaped bill, disproportionately large toenails. Has narrow, inconspicuous rufous supercilium; lores and auriculars grizzled and flammulated greyish, brownish and dark buff; malar area reddish-rufous; crown dark reddish-brown, faint shaft spotting on forehead; upperparts reddish-brown, hint of more reddish collar; wings mostly dark reddish-brown, bend of wing dark ochraceous; tail rounded, shafts slightly stiffened basally, slightly pointed tips with 1 mm of shaft without barbs (or barbs worn off), dark reddish-

chestnut; throat orange-rufous, faint paler shaft streaks on lower throat; breast orange-rufous with faint paler shaft streaks, belly slightly duller with barely a trace of streaks, flanks and undertail-coverts darker; iris brown to dark brown; upper mandible greyish-brown to greyish-brown, lower mandible grey to silvery bluish; tarsus and toes olive to olive-green. Sexes alike. Juvenile has darker crown with dark rufescent spots, slightly darker and less rufescent back, more conspicuous brighter supercilium, whitish lores, reddish rufescent spots on side of neck, paler underparts with blackish feathers edges producing strongly scalloped pattern. **Voice.** Song a distinctive, ascending, accelerating series of peculiar low, harsh, chattering nasal notes, lasts 3–5 seconds, recalls songs of *Syndactyla*; call a loud, hoarse, irritated, low-pitched “chack”.

**Habitat.** Tropical lowland evergreen forest and river-edge forest, primarily in or near *Guadua* bamboo thickets in floodplain forest; locally *Gynerium* cane thickets along rivers. To 1300 m.

**Food and Feeding.** Recorded dietary items are spiders, larval Coleoptera, Dermaptera. Forages singly or in pairs, occasionally in mixed-species flocks; in dense undergrowth, occasionally to mid-storey. Rapidly hitches up vertical and inclined stems, with tail crosswise to branch. Searches bamboo and cane stalks, often dead ones, as well as woody vines and *Heliconia* stalks; hammers, excavates, flakes and gleans for food items. Occasionally gleans and pulls at dead leaves. In study in SE Peru, more than 95% of all observed foraging attempts were directed at *Guadua* bamboo stems, with the rest directed at dead leaves and branches of plants other than bamboo.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Rare to locally uncommon. Global population size almost certainly small because of generally patchy distribution of its habitat. Highly fragmented range; conservation status of isolated populations in Brazil poorly known. Occurs in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru; population in that country suggested by one author as c. 2000 pairs. Habitat within main range in Peru and Bolivia relatively intact, but development of region, with road-building and settlement, a threat. Appears reasonably tolerant of selective logging.

**Bibliography.** Aleixo *et al.* (2000), Alonso *et al.* (2001), Angehr & Aucca (1997), Foster *et al.* (1994), Graves & Zusi (1990), Kratter & Parker (1997), Mayr & Vuilleumier (1983), Novas (1978), Parker (1982), Parker & Remsen (1987), Parker, Parker & Plenge (1982), Parker, Stotz & Fitzpatrick (1997), Remsen (2003a), Remsen & Parker (1983), Remsen & Robinson (1990), Remsen & Traylor (1989), Ridgely & Tudor (1994), Schulenberg *et al.* (2000), Servat & Pearson (1991), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Vaurie (1971b), Whitney (1997), Whittaker & Oren (1999), Zimmer *et al.* (1997).

### 191. Bolivian Recurvebill

#### *Simoxenops striatus*

**French:** Anabate de Bolivie **Spanish:** Ticotico Picolezna Boliviano  
**German:** Ockerstrichel-Blattsphäher

**Other common names:** Bolivian Foliage-gleaner

**Taxonomy.** *Anachilus striatus* Carriker, 1935, Santa Ana, 2200 feet [670 m], Río Coroico, La Paz, Bolivia.

Genus merged by some authors into a broad *Philydor*; close relationship to *Syndactyla* suggested by vocalizations and general behaviour. May form a superspecies with *S. ucayalae*. Monotypic.

**Distribution.** Andean foothills of W & C Bolivia (La Paz, Cochabamba, W Santa Cruz).

**Descriptive notes.** 19–20 cm. Fairly large, dark rufous furnariid with streaking both above and below. Has face mostly grizzled and flammulated brownish and rufous; crown and back rich dark reddish-brown with conspicuous dark buff streaks, narrower on crown than on back; rump slightly paler and nearly unstreaked, uppertail-coverts dark chestnut; wings mainly rich dark reddish-brown, bend of wing ochraceous; tail slightly rounded, shafts slightly stiffened basally, slightly pointed tips, distal 1 mm lacking barbs (or barbs worn off), dull chestnut; malar area and throat orange-rufous, faint paler shaft spotting along lower

margin of throat; breast and upper belly with blurred, irregular streaks of orange-rufous and brown, these virtually disappearing on rich brown lower belly; undertail-coverts more chestnut, with ochraceous shaft streaking; iris dark; bill grey; tarsus and toes greyish. Sexes alike. Juvenile not described, but a museum specimen with dark scalloping on upper breast and lower throat (similar to pattern of juvenile *S. ucayalae*) may represent this plumage. **Voice.** Song a harsh, staccato, rattling, ascending series that levels in pitch and then ends abruptly, c. 3 seconds long, similar to that of *S. ucayalae*; call a raspy “chet” and nasal, scolding “naah”.

**Habitat.** Humid foothill and lower montane forest; 650–900 m.

**Food and Feeding.** Arthropods. Regularly in mixed-species flocks, foraging mainly in dense undergrowth, occasionally ranging into subcanopy. Gleans, pecks and probes on dead branches, debris, and epiphytes. Relatively smaller bill than that of *S. ucayalae* suggests that it does proportionately less hammering and chiselling of stems and branches than does that species.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Bolivian and Peruvian Lower Yungas EBA. Rare; known from few localities, and few specimens. Present in Pilon Lajas Biosphere Reserve, in La Paz, Carrasco National Park, in Cochabamba, and Amoró National Park, in Santa Cruz. In last of those, at least 4 birds found in area of 0.5 km<sup>2</sup> in early 1990s and total numbers in park suggested as being reasonably good. Global population estimated at 2500–10,000 individuals; declining as a result of habitat destruction. Forest in its narrow elevational range is under intense pressure from agricultural expansion and conversion, and much of its range has been deforested; encroachment by settlers into protected areas a major problem. Effective protection of habitat considered a conservation priority.

**Bibliography.** Bond & Meyer de Schauensee (1941, 1942, 1943), Carriker (1935a), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Parker (1982), Parker *et al.* (1992), Remsen & Parker (1995), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995), Whitney *et al.* (1994).

## Genus *ANCISTROPS* P. L. Sclater, 1862

### 192. Chestnut-winged Hookbill

#### *Ancistrops strigilatus*

**French:** Anabate à bec crochu **Spanish:** Ticotico Picoganchito  
**German:** Hakenschnabel-Blattsphäher  
**Other common names:** Spix's Hookbill

**Taxonomy.** *Thamnophilus strigilatus* Spix, 1825, no locality given = Río Solimões, Brazil.

Plumage and distribution suggest that closest relative of genus is *Philydor*. Proposed race *cognitus*, from lower R Tapajós (Brazil), described as more ochraceous and paler above, more buffy below, particularly throat, which has fewer dusky spots, with supercilium more buff; these characters, however, bridged by individual variation in series from farther W. Monotypic.

**Distribution.** SE Colombia (S from S Meta and W Vaupés), E Ecuador, E Peru, Amazonian Brazil (mostly S of R Amazon, E to lower R Tapajós) and N Bolivia (Pando, La Paz).

**Descriptive notes.** 17–18 cm; 30–39 g. Rather distinctive furnariid, with strongly hooked bill like that of an antshrike (*Thamnophilus*). Has broad whitish to buff supercilium; lores grizzled brownish and buff, auriculars brown with buff-whitish streaks; crown very dark brown with narrow but conspicuous golden-buff streaks; back like crown but somewhat paler and more greyish-olive (variable), streaks paler and not quite so sharply defined, rump and uppertail-coverts lighter brown with fainter streaks; wing-coverts mostly dull chestnut with pale shafts, remiges with dull chestnut outer webs, dark fuscous inner webs and tips; tail

nearly square, bright rufous; malar area yellowish-buff, becoming mottled posteriorly, throat pale yellowish-buff with faint dull brownish flecking; breast dull yellowish-buff with blurry dull brownish streaks, these fading into faintly streaked belly; flanks dull brownish with yellowish-buff streaking, undertail-coverts mottled dull buff and light brownish; iris brown; upper mandible blackish to dark horn, lower mandible blue-grey to bluish-ivory; tarsus and toes yellowish-brown to pale brownish-olive. Sexes alike. Juvenile has less regular streaks on upperparts, darker and narrower streaking on underparts. **Voice.** Song a fast, ascending trill that increases in loudness as it levels off in pitch, then ends abruptly; also described as nasal, “tyew-tyew”, often followed by or interspersed with bouts of chattering, in all lasting 5–10 seconds or more; also prolonged, sometimes quavering

trill up to 30 seconds or more. Call a harsh, buzzing “bzzt”; short, ascending trill (similar to song of *Philydor ruficaudatus*) also described.

**Habitat.** Tropical lowland evergreen forest, mostly *terra firme*, locally in *várzea*; mostly below 500 m, locally to 900 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks. Moves slowly along large branches and within dense vine tangles, usually in upper storey. Gleans food items, but substrate use not well known; in study in SE Peru, 32% of foraging manoeuvrers were directed at dead leaves.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common. Occurs in many protected areas, including Amacayacu National Park, in Colombia, Cuyabeno Reserve, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Cristalino State Park, in Brazil.

**Bibliography.** Angehr & Aucca (1997), Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1925), Foster *et al.* (1994), Gyldenstolpe (1945a, 1951), Hilty & Brown (1986), Munn (1985), Oren & Parker (1997), Parker & Bailey (1991), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rosenberg (1997), Salaman *et al.* (1999), Schulenberg & Remsen (1982), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Zimmer, J.T. (1930), Zimmer, K.J. *et al.* (1997).

## Genus *HYLOCTISTES* Ridgway, 1909

### 193. Striped Woodhaunter

#### *Hyloctistes subulatus*

**French:** Anabate forestier    **German:** Strichelrücken-Waldspäher    **Spanish:** Ticotico Listado  
**Other common names:** Striped Foliage-gleaner, Striped Leaf-gleaner; Western Woodhaunter (races N & W of Andes); Eastern Woodhaunter (races E of Andes)

**Taxonomy.** *Sphenura subulata* Spix, 1824, Amazon River.

Included in genus *Philydor* by some authors. Vocal differences accompanied by marked plumage differences between trans-Andean and cis-Andean populations indicate that two species are almost certainly involved. Six subspecies recognized.

**Subspecies and Distribution.**

*H. s. nicaraguae* A. H. Miller & Griscom, 1925 - E Nicaragua.

*H. s. virgatus* (Lawrence, 1867) - Costa Rica and W Panama (E to Veraguas).

*H. s. assimilis* (Berlepsch & Taczanowski, 1884) - E Panama (W from E Colon) and W Colombia S to W Ecuador (S to NW Azuay and El Oro).

*H. s. cordobae* Meyer de Schauensee, 1960 - NW Colombia (Antioquia, S Córdoba, and S in Magdalena Valley to Boyacá).

*H. s. subulatus* (Spix, 1824) - S Venezuela (Amazonas, S Bolívar), SE Colombia (S from S Meta and Vaupés), E Ecuador, E Peru, Amazonian Brazil (E to R Negro and, S of Amazon, to Pará) and N Bolivia (S to La Paz and Beni).

*H. s. lemae* Phelps, Sr. & Phelps, Jr., 1960 - SE Venezuela (Sierra de Lema, in SE Bolívar).

**Descriptive notes.** 17–18 cm; 24–35 g. Distinctive furnariid, with plumage pattern and bill shape reminiscent of *Xiphorhynchus* woodcreepers. N nominate race has face mostly dark brownish with golden-buff streaking, narrow pale eyering and line behind eye, lores grizzled brownish and buff; crown dark brownish, golden-buff shaft streaks and oblong spots on forehead elongating into streaks on crown, these becoming still longer and broadening on rich dark brown back, but less distinct posteriorly; lower back becoming chestnut with hint of streaks, uppertail-coverts chestnut; wings mainly rufescent brown; tail rounded, shafts slightly stiffened basally, blunt tips, chestnut; chin

light buff-brown, faintly streaked darker, streaks becoming more prominent on lower throat; breast dull medium brown with broad blurred golden-buff streaks, fading posteriorly, belly rich tawny-brown, flanks darker brown; iris brown to dark brown; upper mandible dark grey to brown to fuscous horn, lower mandible often slightly paler; tarsus and toes fuscous brown to olive-grey to grey-brown. Sexes alike. Juvenile has less distinct pattern of streaking, slightly paler underparts, some mottling on throat. Race *lemae* differs from nominate in having crown and underparts more distinctly streaked, back and underparts more

olivaceous, less brownish, chin more yellowish, less buffy; *assimilis* is darker than previous, more rufescent above, less streaked above (little on crown), with rump and tail darker, underparts darker, more olivaceous (less tawny) and less streaked; *cordobae* is like previous, but throat and face paler and more yellowish, breast and back paler and more olive, dusky edges of crown feathers more contrasting, bill longer, also described as differing from next in more uniformly coloured upperparts lacking streaks on back and reduced streaking on breast; *virgatus* has rump darker, more chestnut, streaks on crown restricted to a few feathers, narrow streaks on upper back, underparts more olivaceous; *nicaraguae* described as darker, blacker-backed than last, back more heavily streaked, more heavily streaked below, especially on lower throat and breast, with flanks more olive, less rufescent. **Voice.** Song N & W of Andes described as a series of variable duration of loud, sharp nasal notes, “kip, yip-yip-yip-yip-yip”, or of “keeu” or “kick” notes, evenly pitched and spaced; E of Andes 2 (occasionally up to 4) loud whistled “tyew” or “tseew” notes followed by softer, low-pitched rattling “tr-r-r-r-r-r”, or sometimes just series of 2–5 “tseew” notes. Call note of both groups similar, a sharp raspy “chook”, “squirk” or “squirt”; dry chattered “zeck-zeck-zeck” also described from Costa Rica.

**Habitat.** Flooded tropical evergreen forest, including *terra firme* and *várzea*, and tall second growth; locally occurs in lower montane evergreen forest. Recorded mostly below 1100 m, but locally up to 1700 m.

**Food and Feeding.** Diet primarily Orthoptera, Coleoptera and spiders; Heteroptera and small lizards and frogs also recorded. Generally forages singly, regularly to usually in mixed-species flocks; in understorey and mid-storey, occasionally to subcanopy. Gleans and probes for arthropods in debris, dead leaves, epiphytes, including bromeliads and aroids (Araceae), palm fronds, and dense vegetation, often by “burrowing” in; often searches along major branches and vines, and near trunk. In Costa Rica and at two sites in SE Peru, 70%, 63% and 85%, respectively, of observed foraging manoeuvres were directed at dead leaves.

**Breeding.** Nestlings in Feb in Colombia. Presumably monogamous. One nest described, a shallow pad of rachides of compound leaves placed at end of tunnel in dirt bank; estimated territory size 12 ha in transitional forest in SE Peru. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common. Densities of 4–7/km<sup>2</sup> in transitional forest in SE Peru. Occurs in many protected areas, e.g. Corcovado National Park, in Costa Rica, Cueva de los Guácharos National Park and Río Nambi Natural Reserve, in Colombia, Cuyabeno Reserve and Río Palenque Science Centre, in Ecuador, and Tambopata-Candamo Reserved Zone, in Peru.

**Bibliography.** Angehr & Aucca (1997), Borges *et al.* (2001), Burton (1975), Cadena, Álvarez *et al.* (2000), Chapman (1926), Cory & Hellmayr (1925), Foster *et al.* (1994), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee (1960), Munn (1985), Munn & Terborgh (1979), Oren & Parker (1997), Parker & Bailey (1991), Parker & Carr (1992), Parker *et al.* (1982), Phelps & Phelps (1960), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Robinson *et al.* (1990), Rodner *et al.* (2000), Rosenberg (1997), Salaman (1994), Salaman, Donegan & Cuervo (2002), Schmitt & Schmitt (1987), Schulenberg & Remsen (1982), Schulenberg *et al.* (2001), Sick (1993, 1997), Sillett *et al.* (1997), Slud (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon, *et al.* (1997), Wetmore (1972), Willard *et al.* (1991), Zimmer (1936c).

## Genus *PHILYDOR* Spix, 1824

### 194. Rufous-tailed Foliage-gleaner

#### *Philydor ruficaudatum*

**French:** Anabate rougequeue **German:** Olivrücken-Blattspäher **Spanish:** Ticotico Colirrufo

**Taxonomy.** *Anabates ruficaudatus* d'Orbigny and Lafresnaye, 1838, Yuracarés (probably in Cochabamba), Bolivia.

Has no obvious sister-species. Races intergrade extensively; populations from SE Colombia included within race *flavipectus* but may be intergrades between that race and *subflavescens*; populations from the Guianas and NE Brazil are apparently intergrades between *flavipectus* and nominate; and those from SE Peru between *subflavescens* and nominate. Quantitative analysis, with more thorough sampling, is likely to reveal that all variation is clinal and not worthy of nomenclatural recognition. Species name often spelt "*ruficaudatus*", but must agree with neuter gender of genus. Three subspecies tentatively recognized.

#### **Subspecies and Distribution.**

*P. r. flavipectus* Phelps, Sr. & Gilliard, 1941 - SE Colombia (S from W Meta and Vaupés), SE Venezuela (S from C Amazonas and NW Bolívar), the Guianas and NE Brazil.

*P. r. subflavescens* Cabanis, 1873 - E Ecuador (very local, near Andes) and E Peru.

*P. r. ruficaudatum* (d'Orbigny & Lafresnaye, 1838) - the Guianas, NE & Amazonian Brazil (Amazonas E to N Maranhão), SE Peru (E Ucayali) and N Bolivia (S to Cochabamba and NE Beni).

**Descriptive notes.** 16-17 cm; 21-32 g. Rather plain, dull, medium-sized furnariid; the only *Philydor* with some ventral streaking. Has broad, conspicuous dull ochraceous eyering, narrow buff-yellow supercilium extending posteriorly, dark olive postocular band; lores, auriculars and area below eye olive-brownish with yellowish-buff flecking and streaking; crown dark olive with faint paler shaft spots, becoming streaks on hindcrown; back and rump dark olive, some pale shaft streaks on upper back; uppertail-coverts tipped rufous; wings mainly dark olive-brown, conspicuously darker primary coverts; tail nearly square, shafts slightly stiffened basally, rounded tips, rufous; malar area buff-yellow, narrow dark brown malar streak; throat buff-yellow, darker feather bases showing through irregularly; breast dull buff-yellow with blurry streaks of olivaceous brown, belly mostly dull buff yellow with hint of streaking, flanks and undertail-coverts slightly darker, more olivaceous; iris brown; upper mandible blackish to greyish-brown, lower mandible paler, greenish-grey to olive-green; tarsus and toes yellowish-brown to olive-green. Sexes alike. Juvenile is browner, less olive, on upperparts, darker, less yellowish, below, supercilium more conspicuous and ochraceous. Race *flavipectus* is like nominate but throat darker yellowish, underparts in general more yellowish, supercilium, auriculars and underwing-coverts more ochraceous; *subflavescens* supposedly has clearer yellow throat than nominate, less noticeable streaking below. **Voice.** Song a loud, staccato series of up to 25 "te" or "ke" notes, descends and accelerates at end, or on same pitch, accelerating, then decelerating slightly at end, c. 3-3.5 seconds long; also shorter, more variable "wt-pt-pt, wit-wit-wit, d-d-d-d-d-d-d-d", c. 1.5-2 seconds. Call note undescribed.

**Habitat.** Tropical lowland evergreen forest and seasonally flooded forest; mostly *terra firme* forest, locally tall *várzea*. Mostly below 850 m; to 1300 m in Venezuela.

**Food and Feeding.** Diet primarily Orthoptera, Coleoptera, and spiders; Heteroptera also recorded. Forages singly or in pairs, almost always in mixed-species flocks, frequently in association with *P. erythrocerum*; from mid-storey to canopy. Dead-leaf specialist; gleans arthropods from dead leaves, occasionally foliage. In a study in SE Peru, 92% of foraging manoeuvres were directed at dead leaves, and 39% of these at undehiscent leaves at branch tips (most avian dead-leaf specialists search fallen leaves); in another study there, 52% of foraging manoeuvres directed at dead leaves, the rest at live foliage, branches (especially undersides of branches 1-4 cm in diameter) and vine stems.

**Breeding.** No information; nest not described. Estimated territory size 12 ha in transitional forest in SE Peru.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to locally common. Densities of 3-5/km<sup>2</sup> found in transitional forest in SE Peru, and 1-9/km<sup>2</sup> at four *terra firme* sites in French Guiana. Occurs in several protected areas, e.g. Manu National Park and Biosphere Reserve, in Peru.

**Bibliography.** Angehr & Auca (1997), Blake (1950b), Cadena, Álvarez *et al.* (2000), Chapman (1926), Cory & Hellmayr (1925), Foster *et al.* (1994), Gyldenstolpe (1951), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Munn (1985), Munn & Terborgh (1979), Oren & Parker (1997), Parker *et al.* (1982), Parkes (1974), Pinto (1978), Remsen (2003a), Remsen & Parker (1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1995, 1997), Robinson *et al.* (1990), Rodner *et al.* (2000), Rosenberg (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Taczanowski (1884), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thiollay (1986, 1988a, 1988b, 1994), Tostain *et al.* (1992), Zimmer, J.T. (1935a), Zimmer, K.J. *et al.* (1997).

### 195. Slaty-winged Foliage-gleaner

#### *Philydor fuscipenne*

**French:** Anabate à ailes sombres **German:** Schieferflügel-Blattspäher **Spanish:** Ticotico Aligris  
**Other common names:** Rufous-bellied Foliage-gleaner; Dusky-backed/Dusky-winged Foliage-gleaner (*fuscipenne*); Rufous-backed/Santander Foliage-gleaner (*erythronotum*)

**Taxonomy.** *Philydor fuscipennis* Salvin, 1866, Santiago, Veraguas, Panama.

Finer details of plumage suggest that this species is most closely related to *P. erythrocerum*, and was formerly treated as conspecific. Considered by some authors to be closer to *P. pyrrhodes* because of overall plumage similarities. Race *erythronotum* has sometimes been treated as a separate species; disjunct population in W Ecuador probably represents an undescribed taxon. Proposed race *fulvescens*, described from a single specimen from N Colombia, represents a plumage of nominate race. Species name often spelt "*fuscipennis*", but must agree with neuter gender of genus. Two subspecies recognized.

#### **Subspecies and Distribution.**

*P. f. fuscipenne* Salvin, 1866 - C Panama (Veraguas, Coclé, E Colón, Canal area).

*P. f. erythronotum* P. L. Sclater & Salvin, 1873 - E Panama (E from E San Blas and E Panamá) to N & SW Colombia (E to N Santander and N Caldas, S to Chocó; Nariño) and W Ecuador (S Pichincha S to El Oro and NW Azuay).

**Descriptive notes.** 17 cm; 25-28 g. Rather dark *Philydor*. Nominate race has vague eyering pale rufescent ochre, conspicuous supercilium pale rufescent ochre, darkening posteriorly, postocular band dull dark brownish, auriculars and band below eye dull dark brownish with dull rusty flammulations, lores grizzled fuscous and buff; crown dark brown with very faint dark rufescent shaft spotting, indistinct dark rusty-rufous collar extending to side of neck; back rich rufescent brown, becoming chestnut-rufous on rump and uppertail-coverts; wing-coverts dull brown, primary coverts dark slaty brown, remiges slaty grey-brown; tail rounded,

shafts slightly stiffened basally, somewhat rounded tips, rufous-chestnut; throat orange-buff to tawny-orange or bright rusty; underparts similar, slightly deeper rufescent on central breast, progressively duller and slightly paler towards belly, side of upper breast browner, sides and flanks to undertail-coverts darker rufescent brown or chestnut-brown; iris brown; upper mandible grey to blackish, lower mandible grey to horn; tarsus and toes grey-green to greenish-yellow. Sexes alike. Juvenile is generally more rufous, with ochraceous underparts. Race *erythronotum* is paler and duller throughout, in Ecuador more ochraceous below. **Voice.** Song a monotonic accelerating trill; contact call a sharp "chef".

**Habitat.** Tropical lowland evergreen forest, usually hilly, also tall second growth; mainly 500-1000 m, locally to 1200 m.

**Food and Feeding.** Diet primarily Orthoptera, spiders and their eggs, and Coleoptera; Heteroptera and small lizards also recorded. Forages solitarily or in pairs, usually in mixed-species flocks, from undergrowth to lower mid-storey. Usually works along or climbs up branches; acrobatically gleans arthropods from dead leaves and epiphytes; probably a dead-leaf specialist.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to rare; uncommon to locally fairly common in Panama. Rare to locally fairly common in W Ecuador, and occurs in Rio Palenque Science Centre; disjunct population in that country considered vulnerable because of extensive destruction of lowland forests.

**Bibliography.** Anon. (1998a), Cory & Hellmayr (1925), Hilty & Brown (1983, 1986), Kratter & Parker (1997), Meyer de Schauensee (1950), Parker & Carr (1992), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Salaman, Donegan & Cuervo (2002), Stotz *et al.* (1996), Todd (1950b), Wetmore (1972), Zimmer (1935a).

### 196. Rufous-rumped Foliage-gleaner

#### *Philydor erythrocerum*

**French:** Anabate à croupion roux **German:** Rostbüzel-Blattspäher **Spanish:** Ticotico Lomirrufo  
**Other common names:** Rufous-rumped Leaf-gleaner; Ochre-bellied Foliage-gleaner (*ochrogaster*)

**Taxonomy.** *Anabates erythrocerum* Pelzeln, 1859, Manaus, Brazil.

Finer details of plumage suggest that this species is most closely related to *P. fuscipenne*, and was formerly treated as conspecific. Distinctive montane race *ochrogaster* often treated as a separate species; despite striking plumage differences, however, song is similar to, if not indistinguishable from, that of nominate. Race *lyra* varies clinally in plumage coloration from W to E. Species name often spelt "*erythrocerus*", but must agree with neuter gender of genus. Five subspecies recognized.

#### **Subspecies and Distribution.**

*P. e. erythrocerum* (Pelzeln, 1859) - the Guianas and NE Brazil (E from R Negro, S to R Amazon).

*P. e. subfulvum* P. L. Sclater, 1862 - S Colombia (S from W Meta), E Ecuador and N Peru (N of R Amazon, W of R Ucayali).

*P. e. suboles* Todd, 1948 - SE Colombia (Amazonas) and NW Brazil (N of R Amazon, E to R Negro).

*P. e. lyra* Cherrie, 1916 - Amazonian E Peru (S of R Amazon, E of R Ucayali), Brazil (E, S of R Amazon, to N Maranhão, S to Mato Grosso) and N Bolivia (Pando, N Beni).

*P. e. ochrogaster* Hellmayr, 1917 - Andes from C Peru (S from Huánuco) S to NC Bolivia (S to Cochabamba, sight reports to NW Santa Cruz).

**Descriptive notes.** 14-15 cm; 18-31 g. Rather small, dull *Philydor* with conspicuously contrasting tail. Nominate race has conspicuous narrow supercilium and eyering pale tawny-buff, rest of face dark fuscous brown, some dull ochraceous shaft streaking on auriculars; crown to back dull, rather dark olive-brown, crown with slightly paler faint shaft spots; rump and uppertail-coverts bright chestnut; wings dull dark olive-brown, slightly darker primary coverts; tail slightly rounded, shafts slightly stiffened basally, rounded tips, bright rufous; throat and malar area (flaring into side of neck) pale yellowish-buff; breast and belly dull medium brownish, tinged olive, flanks and undertail-coverts slightly darker, slightly tinged dark rufescent; iris brown to dark brown; upper mandible blackish to brownish, lower mandible paler, horn-brown to pinkish-grey; tarsus and toes greyish-green to yellowish-olive. Sexes alike. Juvenile has crown more rufescent, underparts less yellowish, supercilium and malar area more conspicuous, more rufous-orange, and extending posteriorly

On following pages: 197. Chestnut-winged Foliage-gleaner (*Philydor erythropterum*); 198. Ochre-breasted Foliage-gleaner (*Philydor lichtensteini*); 199. Alagoas Foliage-gleaner (*Philydor novaesi*); 200. Black-capped Foliage-gleaner (*Philydor atricapillus*); 201. Buff-fronted Foliage-gleaner (*Philydor rufum*); 202. Cinnamon-rumped Foliage-gleaner (*Philydor pyrrhodes*); 203. Russet-mantled Foliage-gleaner (*Philydor dimidiatum*); 204. Dusky-cheeked Foliage-gleaner (*Anabazenops dorsalis*); 205. White-collared Foliage-gleaner (*Anabazenops fuscus*).

to meet vague rufous-orange collar. Race *lyra* is like nominate, but upperwing-coverts and outer webs of remiges brighter, with cinnamon or rusty tinge, back redder, underparts slightly more buffy, varies clinally, populations from E of range with back more greenish-olive (less brownish) and underparts more yellowish (less buffy); *suboles* differs from previous in having duller and paler underparts, without buff wash, more olivaceous (less brownish) wing edgings; *subfulvum* is like nominate, but rump less rufous, and underparts slightly more ochraceous; *ochrogaster* very different from others, has upperparts tinged tawny olivaceous,

underparts tawny-ochraceous, rump more rufous, supercilium and throat brighter ochraceous. VOICE. Song a slightly ascending and then descending series of 4-6 high notes, "chu, chee, chee, ché, chu"; call notes described as shrill "wheeeeyk" and "cheeyu" or "chak".

**Habitat.** Tropical lowland evergreen forest, mainly *terra firme* but locally in *várzea*; mainly below 1300 m. Montane evergreen forest at 800-1650 m in Andes (*ochrogaster*).

**Food and Feeding.** Recorded dietary items (race *lyra*) are spiders, Orthoptera (Acridoidea), Coleoptera (including families Cicindellidae, Curculionidae), Lepidoptera, Hymenoptera. Forages singly, occasionally in pairs, usually in mixed-species flocks, frequently in association with *P. ruficaudatum*; mainly in subcanopy, regularly to mid-storey and canopy. Dead-leaf specialist. Gleans and pulls arthropods from dead leaves, palm fronds and debris, especially in vine tangles; often uses acrobatic manoeuvres to reach dead leaves. At a site in SE Peru, 80% of observed foraging manoeuvres were directed at dead leaves, and once seen to hang from one foot and grab and pull dead leaf with other foot; at another site in same region, 50% of foraging manoeuvres directed at dead leaves, the remainder at branches (especially undersides of branches 1-4 cm in diameter) and vine stems.

**Breeding.** Breeds during dry season in French Guiana. One nest described, in hole 30 cm deep in old tree stump, nest-chamber with pad of wood fibres; clutch 2 eggs; only one bird attended nest. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Densities estimated at 9-20/km<sup>2</sup> in transitional forest in SE Peru and 10-28/km<sup>2</sup> at four *terra firme* sites in French Guiana. Occurs in many protected areas, including Raleigh Falls-Voltzberg National Park, in Surinam, Cuyabeno Reserve and Rio Palenque Science Centre, in Ecuador, Manu National Park and Biosphere Reserve, in Peru, and Cristalino State Park, in Brazil.

**Bibliography.** Alonso *et al.* (2001), Blake (1950b), Bond (1945), Cory & Hellmayr (1925), Graves & Zusi (1990), Gyldenstolpe (1945b, 1951), Haverschmidt & Mees (1994), Hilty & Brown (1986), Munn (1985), Novaes (1990), Parker & Bailey (1991), Parker, Bates & Cox (1992), Parker, Parker & Plenge (1982), Pinto (1978), Remsen (2003a), Remsen & Parker (1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins *et al.* (1985), Robinson & Terborgh (1995, 1997), Robinson *et al.* (1990), Rodner *et al.* (2000), Romero (1978), Rosenberg (1997), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thiollay (1986, 1988a, 1988b, 1994), Todd (1948b), Tostain *et al.* (1992), Wetmore (1972), Zimmer (1930, 1935a).

## 197. Chestnut-winged Foliage-gleaner

### *Philydor erythropterus*

**French:** Anabate à ailes rousses

**Spanish:** Ticotico Alicastaño

**German:** Kastanienflügel-Blattsphäer

**Taxonomy.** *Anabates erythropterus* P. L. Selater, 1856, "Bogotá".

No obvious sister-species in genus. Race *diluviale* possibly represents E extreme of clinal variation of nominate; more thorough analysis required. Species name often spelt "*erythropterus*", but must agree with neuter gender of genus. Two subspecies tentatively recognized.

**Subspecies and Distribution.**

*P. e. erythropterus* (P. L. Selater, 1856) - S Venezuela (E Amazonas, S Bolívar), SE Colombia (S from W Meta), E Ecuador, E Peru, Brazil S of R Amazon (W Amazonas E to R Madeira) and NE Bolivia (S to La Paz and N Beni).

*P. e. diluviale* Griscom & Greenway, 1937 - E Brazil (C Pará, W Maranhão).

**Descriptive notes.** 17-19 cm; 28-36 g. Slightly larger-billed than congeners and with more contrast between wings and back. Has indistinct tawny supercilium from near bill base, where almost orange-buff, to behind eye, becoming narrower and duller posteriorly; broad but indistinct eye-ring buffy, postocular area dark grey; auriculars dull brownish, bordered below by indistinct darker streak that extends forwards to brownish lores; crown dull brownish-grey with buff shaft streaks, fading posteriorly; back and rump dull greyish-brown, uppertail-coverts slightly paler; wing-coverts rufous with blackish shaft streaks, remiges

slightly darker with dark fuscous tips, contrastingly darker chestnut primary coverts; tail slightly rounded, shafts slightly stiffened basally, rather rounded tips, dark rufous; throat and malar area ochraceous yellow; breast light dull brownish with vague ochraceous tawny streaking that fades posteriorly, belly slightly paler, flanks and undertail-coverts dull, light greyish-brown; iris brown to dark brown; upper mandible dark brown to brownish, lower mandible paler, greenish-horn to yellowish-green; tarsus and toes yellowish-green to light greenish-olive. Sexes alike. Juvenile is slightly paler and duller throughout, throat darker, breast lacking or almost lacking streaks. Race *diluviale* was described as having browner, less greyish, upperparts, especially on rump and uppertail-coverts, much more buffy breast, browner (less greyish) sides, flanks and undertail-coverts. VOICE. Song a fast, buzzy, slightly accelerating, quavering or slightly descending trill, duration 2-3 seconds; call undescribed.

**Habitat.** Tropical lowland evergreen forest and flooded forest; mostly *terra firme* and transitional forest, also *várzea* forest (possibly primarily so in N portions of range). Mostly below 500 m, locally to 1200 m.

**Food and Feeding.** Arthropods. Usually in pairs, almost always in mixed-species flocks, from mid-storey to canopy. Acrobatically gleans and pulls food items from live and dead leaves, some-

times twigs, usually towards ends of branches in outer shell of tree's foliage.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Density estimated at 4-5/km<sup>2</sup> in transitional forest in SE Peru. Occurs in several protected areas, including Amacayacu National Park, in Colombia, and Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru.

**Bibliography.** Cadena, Alvarez *et al.* (2000), Cory & Hellmayr (1925), Foster *et al.* (1994), Gyldenstolpe (1945a, 1951), Hilty (2003a), Hilty & Brown (1986), Munn (1985), Parker & Bailey (1991), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Robinson *et al.* (1990), Rodner *et al.* (2000), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Taczanowski (1884), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990).

## 198. Ochre-breasted Foliage-gleaner

### *Philydor lichtensteini*

**French:** Anabate de Lichtenstein

**Spanish:** Ticotico Ocráceo Chico

**German:** Schuppenscheitel-Blattsphäer

**Other common names:** Lichtenstein's Foliage-gleaner

**Taxonomy.** *Philydor Lichtensteini* Cabanis and Heine, 1859, Brazil. Monotypic.

**Distribution.** SE Brazil (S Bahia, S Goiás and S Mato Grosso do Sul S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

**Descriptive notes.** 15-17 cm; 18-24 g. The shortest-billed member of genus. Has broad, sharply defined supercilium and weakly defined eyering pale ochraceous, conspicuous postocular band dull dark brownish, auriculars dull rufous-ochre, lores dull pale brownish; crown dull grey-brown with vague paler shaft streaking, partly concealed blackish spotting on bases of hindcrown feathers; back rufescent brown, rump and uppertail-coverts slightly paler; wings rufous-brown, dusky tips of remiges; tail slightly rounded, shafts slightly stiffened basally, somewhat pointed tips (hint of bare "spine" in fresh plumage), dull rufous

except for rufescent brown outer webs of central rectrices; throat and malar area bright ochraceous buff, becoming richer on breast; lower breast and rest of underparts slightly duller; iris brown; upper mandible brownish-grey, lower mandible light grey; tarsus and toes greenish-grey. Sexes alike. Juvenile has less uniformly coloured underparts with feathers tipped greyish. VOICE. Song a fast, descending series of dry notes.

**Habitat.** Tropical lowland evergreen forest and secondary forest; from near sea-level to 800 m.

**Food and Feeding.** Recorded dietary items are Coleoptera (including Curculionidae), spiders, and Lepidoptera. Usually in mixed-species flocks; forages from mid-storey to canopy. Probably dead-leaf specialist. Acrobatically gleans and pulls arthropods from dead leaves and debris; hangs down to inspect undersides of branches.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to common. In Brazil, common in Iguazu National Park, fairly common in Tijuca National Park, uncommon in Augusto Ruschi Biological Reserve, and rare in Itatiaia National Park; present also in Rio Doce and Serra do Mar State Parks. In Paraguay, common in Caaguazú, Cerro Corá and Ybicuí National Parks, and present also in San Rafael National Park. In Argentina, occurs in Iguazú National Park. Extensive deforestation within its relatively small range has dramatically reduced amount of available habitat; nevertheless, seems able to persist in degraded forest fragments.

**Bibliography.** Anon. (2003d), Aleixo (1997), Aleixo & Galetti (1997), dos Anjos *et al.* (1997), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Goerck (1999a), Gonzaga *et al.* (1995), Hayes (1995), Hayes & Scharf (1995a, 1995b), Madroño, Clay *et al.* (1997), Madroño, Robbins & Zyskowski (1997), Marini (2001), Mazar Barnett & Pearman (2001), Naka *et al.* (2002), Narosky (1983), Navas & Bö (1988), Olrog (1963a), Parker & Goerck (1997), de la Peña (1988), Pinto (1978), Remsen (2003a), Ridgely & Tudor (1994), Robbins *et al.* (1999), Schubart *et al.* (1965), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Willis & Schuchmann (1993).

## 199. Alagoas Foliage-gleaner

### *Philydor novaesi*

**French:** Anabate d'Alagoas

**German:** Alagoasblattsphäer

**Spanish:** Ticotico de Alagoas

**Other common names:** Greater Black-capped/Novaes's Foliage-gleaner

**Taxonomy.** *Philydor novaesi* Teixeira and Gonzaga, 1983, Serra Branca, c. 9°15' S, 25°50' W, c. 550 m, Município de Murici, Alagoas, Brazil.

Evidently forms a superspecies with *P. atricapillus*. Monotypic.

**Distribution.** Alagoas, in NE Brazil.

**Descriptive notes.** 18 cm; 30-38 g. Has conspicuous pale buff supercilium and eyering, blackish-brown postocular band, pale buff auriculars bordered below by blackish-brown band; lores dull buffy rufous; crown dark brown, faint shaft spotting on forehead, hint of streaks in centre of crown; back dull rufous-brown, rump slightly more rufous, uppertail-coverts brighter rufous; wings mainly dark rufous-brown, primary coverts and centres of greater secondary coverts darker, tips of remiges dark fuscous; tail slightly rounded, shafts slightly stiffened basally, nearly rounded tips, bright rufous; chin, throat and underparts

dull rufescent, flanks slightly duller, undertail-coverts more rufous; iris brown; bill blackish-brown

above, ivory below; tarsus and toes greenish-horn. Differs from similar *P. atricapillus* in being less rufous throughout, with less bold, less contrasting face pattern. Sexes alike. Juvenile undescribed. **VOICE.** Song a trilled series of notes; alarm "thoor" or "theer".

**Habitat.** Tropical lowland evergreen forest and humid, hilly second-growth forest; 400–550 m.

**Food and Feeding.** Recorded dietary items are Coleoptera and their larvae, Orthoptera (Acrididae), and ants. Observed singly or in pairs, usually in mixed-species flocks, from undergrowth to mid-storey. Acrobatically gleans food items from dead leaves, live foliage, debris and bark; seen also to pull larvae from dead wood.

**Breeding.** No information. Immature found in Mar.

**Movements.** Resident.

**Status and Conservation.** CRITICAL. Restricted-range species; present in Atlantic Slope of Alagoas and Pernambuco EBA. Rare; range extremely small, c. 30 km<sup>2</sup>. Known from just a single site in Alagoas, at Murici, where first discovered in 1979; was not observed between 1992 and 1997, but a single individual recorded in each of following two years, and four in 2000. Global population estimated at 50–249 individuals at end of 20th century; declining rapidly as a result of habitat destruction. Survives in only a patch of forest of c. 1500 ha, the remnant of what was only 8500 ha at time of this species' discovery; although this remaining patch is protected by law, illegal cutting still occurs, and uncontrolled fires are a threat. Forest at Murici is privately owned, and several conservation initiatives aimed at preventing further loss of habitat have proved unsuccessful. Enforcement of protection measures is essential if this species is not to become extinct in the near future.

**Bibliography.** Bernardes *et al.* (1990), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cordeiro (2001), Goerck (2002), Mazar Barnett & Kirwan (1999c), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Teixeira (1986), Teixeira & Gonzaga (1983b, 1985), Teixeira *et al.* (1987), Vuilleumier, LeCroy & Mayr (1992), Wege & Long (1995), Whittaker (1997, 2000).

## 200. Black-capped Foliage-gleaner

### *Philydor atricapillus*

**French:** Anabate à tête noire

**Spanish:** Ticotico Cabecinegro

**German:** Schwarzscheitel-Blattsphäer

**Taxonomy.** *Anabates atricapillus* Wied, 1821, Rio Catolé, Bahia, Brazil.

Evidently forms a superspecies with *P. novaesi*. Named form *Philydor hylobius*, previously believed by some to be an isolated population of present species, in fact represents the juvenile plumage of *Automolus roraimae*. Species name invariable, so, in contrast to the cases of several other taxa currently recognized within *Philydor*, must not be made to agree with neuter gender of genus. Monotypic.

**Distribution.** SE Brazil (S Bahia S to S Mato Grosso do Sul and NE Rio Grande do Sul), E Paraguay and extreme NE Argentina (N Misiones).

**Descriptive notes.** 16–17 cm; 17–27 g. One of the most striking foliage-gleaners, with distinctive "tiger-striped" head pattern, strongly rufous coloration (reported N–S clinal variation from rufescent to olivaceous not corroborated). Has conspicuous pale buff supercilium, becoming light orange-rufous posteriorly, broad pale buff eyering; postocular band blackish-brown, bordered below by band of pale buff, then by another narrower blackish-brown band, this extending anteriorly to beneath gape; lores dull buffy rufous, interrupted by blackish-brown streak that extends anteriorly from crown; crown blackish-brown, faint shaft spotting on

forehead and hint of streaks in centre of crown; back rich rufous-brown, rump slightly paler and more rufous, uppertail-coverts bright orange-rufous; wings mainly rich brown, primary coverts and centres of greater secondary coverts darker, tips of remiges dark fuscous; tail slightly rounded, shafts slightly stiffened basally, nearly rounded tips, bright rufous; chin, upper throat and malar area light orange-rufous, becoming duller and darker on lower throat; breast and belly fairly uniform dark orange-rufous, flanks slightly duller, undertail-coverts bright rufous; iris brown; upper mandible mostly blackish, lower mandible pale grey to greenish-grey; tarsus and toes pale ochre-yellow to light olive-grey. Differs from similar *P. novaesi* in brighter, more rufous coloration, stronger and more contrasting head pattern. Sexes alike. Juvenile has feathers of underparts margined dark brown. **VOICE.** Song a somewhat musical, whistled, fast, sharply descending trill; also gives irregular series of squeaky notes, and "pit-wit".

**Habitat.** Tropical lowland evergreen forest and secondary forest; recorded from near sea-level to 1050 m.

**Food and Feeding.** Various arthropods. In detailed analysis of diet in relation to prey availability in dead leaves, bulk of food found to consist of adult Coleoptera and spiders, with cockroaches (Blattodea), Orthoptera, ootheca, moths and their larvae, Heteroptera, Chilopoda, Diptera and Hymenoptera also represented; in proportion to relative availability, however, strong preference for adult Lepidoptera and ootheca, moderate preference for Coleoptera, spiders and insect eggs, and avoidance of ants. Singly or in pairs, often in mixed-species flocks, from undergrowth to canopy. Works along branches, occasionally clings to trunks; acrobatically gleans and pulls arthropods from dead leaves, debris, vine stems, foliage, epiphytes (especially bromeliads) and bark crevices.

**Breeding.** Little information. Nest not described, but reported to be in hole in dirt bank.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in Brazil; rare in Paraguay. In Brazil, fairly common in Sooretama and Augusto Ruschi Biological Reserves and in Itatiaia and Iguaçu National Parks; uncommon in Serra dos Órgãos National Park. In Paraguay, uncommon in Caaguazú National Park and present in San Rafael National Park. Occurs in Iguaçu National Park, in Argentina. Extensive deforestation within its relatively small range has dramatically reduced the area of this species' habitat. Seems able to persist in small forest fragments and in moderately degraded forest.

**Bibliography.** Alexio & Galetti (1997), dos Anjos *et al.* (1997), Anon. (2003d), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez *et al.* (1999), Cory & Hellmayr (1925), Goerck (1999a), Hayes (1995), Madroño, Clay *et al.* (1997), Madroño, Robbins & Zyskowski (1997), Mallet-Rodrigues (2001), Mazar Barnett & Pearman (2001), Mitchell (1957), Naka *et al.* (1983), Navas & Bó (1988), Olrog (1963a), Parker & Goerck (1997), de la Peña (1988), Pinto (1978), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Willis & Schuchmann (1993).

## 201. Buff-fronted Foliage-gleaner

### *Philydor rufum*

**French:** Anabate roux

**German:** Ockerstim-Blattsphäer

**Spanish:** Ticotico Ocráceo Grande

**Other common names:** Buff-fronted Leaf-gleaner

**Taxonomy.** *Dendrocopus rufus* Vieillot, 1818, Rio de Janeiro, Brazil.

No obvious close relatives. Racial identity of population in C Falcón, in Venezuela, uncertain; presumed to belong with race *colombianum*. Nominat race varies clinally in size, with smallest birds farthest S. Species name often spelt "rufus", but must agree with neuter gender of genus. Seven subspecies recognized.

**Subspecies and Distribution.**

*P. r. panerythrum* P. L. Slater, 1862 - highlands of Costa Rica and W Panama (E to W Chiriqui and Bocas del Toro), and C & E Andes of Colombia (Antioquia, Caldas, and W slope from Santander S to Cundinamarca).

*P. r. colombianum* Cabanis & Heine, 1859 - N Venezuela in C Falcón (Sierra de San Luis) and coastal mountains (Yaracuy, and Carabobo E to Miranda).

*P. r. cuchiverus* Phelps, Sr. & Phelps, Jr., 1949 - Cerro Calentura (N Amazonas) and Cerro El Negro (NW Bolívar), in S Venezuela.

*P. r. riveti* Menegaut & Hellmayr, 1906 - W Andes from Colombia (S from C Chocó) S to NW Ecuador (S to Pichincha, also El Oro).

*P. r. bolivianum* Berlepsch, 1907 - foothills of E slope from Ecuador (S from W Napo) S to C Bolivia (S to Chuquisaca).

*P. r. chapadense* J. T. Zimmer, 1935 - SW Brazil (Mato Grosso, S Goiás).

*P. r. rufum* (Vieillot, 1818) - E & SE Brazil (Minas Gerais, SE Bahia and Espírito Santo S to S Mato Grosso do Sul and N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, NE Corrientes).

**Descriptive notes.** 18–19 cm; 25–36 g. The longest-tailed *Philydor*, and the only one with contrasting forehead and pointed rectrices. Nominat race has ochraceous supercilium exceptionally broad and contiguous with forehead; postocular band dull dark brownish-grey, auriculars dull ochraceous, loreal crescent dark brownish-grey; forehead ochraceous, rest of crown dull brownish-grey with hint of paler shaft streaks; uppermost back also dull brownish-grey, rest ochraceous brown, rump and uppertail-coverts slightly paler; wings mainly bright rufous, primary coverts darker, duller; tail rounded, shafts slightly stiffened basally, strongly pointed

tips (hint of bare "spine" in fresh plumage), dull rufous-brown; throat, malar area and breast glowing ochraceous, blending to duller belly, flanks and undertail-coverts; iris greyish-brown to dark brown to chestnut (source of variation uncertain); upper mandible blackish to dark greyish, lower mandible paler, silvery grey to olive, sometimes black basally; tarsus and toes olive to greyish-green. Sexes alike. Juvenile has narrower forehead band, paler crown, darker and more rufescent underparts. Race *chapadense* is like nominat, but forehead deeper ochraceous, some ochraceous spots spreading to rest of crown, crown paler grey, back more richly coloured; *bolivianum* has crown paler and more olivaceous, not grey, contrasting less with back; *riveti* is smaller, darker on crown and back, more rufous in tail, and breast and belly washed brownish, thus contrasting more with throat; *colombianum* has forehead band narrower, duller, less sharply defined from crown, crown olivaceous (not greyish), back darker, belly much paler; *cuchiverus* is like previous, but supercilium ochraceous rather than buff, *panerythrum* has crown and back paler than last, more greyish, underparts a more uniform and deeper ochraceous. **VOICE.** Song a fast, accelerating series of staccato, metallic notes, "whi-ki-ki-ke-ke-ke-kuh-kuh", sometimes descending slightly at end; evidently similar throughout much of large, disjunct range, but in Costa Rica described as squeaky "woika-woika-woika...". Call a peculiar, squeaky but harsh "shirrrr" or "chur", almost frog-like, and sharp, metallic "skik" or "chik".

**Habitat.** Montane and tropical lowland evergreen forest, and river-edge forest. Mainly humid lower montane forest and hilly tropical forest in N & W parts of range; 800–2500 m in Central America, and 600–1800 m in Andean foothills and tepui region. Mainly tropical lowland evergreen forest in SE parts of range, from near sea-level to 1000 m, locally higher.

**Food and Feeding.** Recorded dietary items are spiders and their eggs, cockroaches (Blattodea), Orthoptera including katydids (Tettigoniidae) and crickets (Gryllidae), Coleoptera, Lepidoptera larvae, and Hemiptera. Singly or in pairs, usually in mixed-species flocks; in montane SE Brazil, up to 20 individuals in a flock. Forages in subcanopy and canopy, occasionally down to understorey. Usually works along horizontal limbs to their tips with side-to-side motion; hangs down frequently in dense foliage. Acrobatically gleans arthropods from dense vegetation, particularly undersides of green leaves; also from bark, moss, debris and dead leaves. Evidently a dead-leaf specialist in Venezuela. In most places, however, is much less a searcher of dead leaves than are congeners: in SE Brazil, more than 82% of observed foraging manoeuvres were directed towards live leaves, 16% towards dead leaves, and the rest towards branches and stems; in SE Peru, 35% of foraging manoeuvres directed at dead leaves, the rest towards live foliage.

**Breeding.** Nestlings in Jun in W Colombia; eggs and nestlings in Nov in NE Argentina. Presumably monogamous. Nest in hole in dirt bank, tree cavity or wall, not clear whether excavated by bird itself or existing burrow adopted (weight of evidence favours latter); nest-chamber lined with fine grass; territory size in SE Peru c. 8–12 ha. Clutch 2–3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to rare in much of its range, but apparent scarcity perhaps in part an artifact of difficulty in detection; fairly common in SE portion of range. Occurs in numerous protected areas, including Henri Pittier National Park, in Venezuela, Podocarpus National Park, in Ecuador, Manu National Park and Biosphere Reserve, in Peru, Iguaçu, Serra da Canastra and Itatiaia National Parks, in Brazil, and Iguaçu National Park, in Argentina.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos *et al.* (1997), Anon. (1998a), Belton (1984), Boesman (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Fjeldså & Maijor (1996), Foster *et al.* (1994), Hayes (1995), Hernández *et al.* (1995), Hilty (1997, 2003a), Hilty & Brown (1983, 1986), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1946a), Munn (1985), Narosky *et al.* (1983), Navas & Bó (1988), Novaes (1961b), Olrog (1963a), Parker & Bailey (1991), Parker & Goerck (1997), Parker *et al.* (1982), de la Peña (1988), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Robbins & Ridgely (1990), Robinson & Terborgh (1995, 1997), Robinson *et al.* (1990), Rodner *et al.* (2000), Rodrigues *et al.* (1994), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Scott & Brooke (1985), Sick (1993, 1997), Slud (1964), Soares & dos Anjos (1999), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Wetmore (1972), Willis (1989), Zimmer (1930, 1935a).

## 202. Cinnamon-rumped Foliage-gleaner

*Philydor pyrrhodes*

**French:** Anabate flamboyant **German:** Zimtbürzel-Blattspäher **Spanish:** Ticotico Lomicanelo

**Taxonomy.** *Anabates pyrrhodes* Cabanis, 1848, coast of Guyana. No obvious sister-species in genus. Monotypic.

**Distribution.** SE Colombia (S from S Meta and Vaupés), S Venezuela (Amazonas, Bolívar, Delta Amacuro) and the Guianas S to E Ecuador, E Peru, Amazonian Brazil (E to N Maranhão, S to W Mato Grosso) and N Bolivia (S to Beni, extreme N Santa Cruz).

**Descriptive notes.** 14–16 cm; 24–35 g. Distinctive, with brightest and most uniformly coloured underparts of all members of genus. Has supercilium and eyering ochraceous, weakly defined postocular area dark rufescent brown, auriculars rufescent brown, lores mostly dull rufescent brownish; crown dark rufescent brown with faint darker scalloping; back rufescent brown, rump rufous, uppertail-coverts bright orange-rufous; wings almost uniform dark fuscous brown; tail slightly rounded, shafts slightly stiffened basally, nearly rounded tips, bright orange-rufous; nearly uniform bright orange ochraceous below, slightly paler

on throat; iris brown to dark brown; upper mandible mostly dark grey to blackish, lower mandible paler, dark grey to silvery grey, sometimes with dark tip; tarsus and toes olive-greenish to yellowish-olive. Sexes alike. Juvenile has browner upperparts, paler and less rufescent throat. **Voice.** Song starts as long low trill, gradually becoming louder, then breaking into louder, vibrating, evenly ascending trill that ends abruptly, duration of whole variable, 4–15 seconds; contact call a low, loud, explosive “chack”, “chakit” or “chichid”.

**Habitat.** Tropical lowland evergreen and flooded evergreen forest; *terra firme* and *várzea* forest, often near streams and usually in areas of high palm density. Mostly below 400 m, locally to 700 m.

**Food and Feeding.** Recorded dietary items include cockroaches (Blattodea). Forages singly or in pairs, occasionally in mixed-species flocks; mostly in undergrowth, less often to mid-storey and subcanopy. Acrobatically gleans and pulls arthropods from dead leaves and debris, often among palm fronds, also from live palm fronds and large leaves, such as those of *Heliconia* and *Arum*; usually in dense vegetation.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon throughout range. Estimated density at two sites in French Guiana 1–3 birds/km<sup>2</sup>. Occurs in many protected areas, including Imataca Forest Reserve and El Dorado, in Venezuela, and Tambopata-Candamo Reserved Zone, in Peru.

**Bibliography.** Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1925), Foster *et al.* (1994), Graves & Zusi (1990), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Kratter & Parker (1997), Novaes (1990), Oren (1990), Parker (1979), Parker & Bailey (1991), Parker *et al.* (1982), Pearson (1975c), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rosenberg (1997), Schulenberg (2002), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer & Bierregaard (1995), Terborgh *et al.* (1984), Thiollay (1986, 1988b, 1994), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer (1935a).

## 203. Russet-mantled Foliage-gleaner

*Philydor dimidiatum*

**French:** Anabate mantelé **German:** Ockerbrauner Blattspäher **Spanish:** Ticotico del Planalto  
**Other common names:** Planalto Foliage-gleaner; Baer's Foliage-gleaner (*baeri*)

**Taxonomy.** *Anabates dimidiatus* Pelzeln, 1859, Sangrador and Rio Manso, Mato Grosso, Brazil. Possibly better placed in genus *Syndactyla*; in several respects (bill shape, vocalizations) more similar to members of that genus than to those of present genus. Species name often spelt “*dimidiatus*”, but must agree with neuter gender of genus. The taxon *S. mirandae*, described from C Brazil (Goiás) and subsequently treated as a race of *S. rufosuperciliata*, is in fact a synonym of present species, presumably of race *baeri*. Latter formerly considered a separate species. Two subspecies recognized.

**Subspecies and Distribution.**

*P. d. dimidiatum* (Pelzeln, 1859) - SC Brazil (S Mato Grosso).

*P. d. baeri* Hellmayr, 1911 - interior SE Brazil (Goiás, Minas Gerais) and EC Paraguay (Concepción).

**Descriptive notes.** 17 cm; 27–32 g. The most uniformly rufescent *Philydor*; rather long, pointed bill with lower mandible slightly upturned. Nominative race has comparatively plain face rufescent orange, deeper on side of neck and on anterior supercilium, somewhat darker auriculars; crown and upperparts bright cinnamon-tinged rufescent brown; wings mostly dark rufescent brown, brighter outer edges of primaries (broad wingband); tail slightly graduated, rectrices with blunt tips, rufous-chestnut; throat and underparts mostly uniform ochraceous rufous, faint pale shaft streaks on breast, flanks more olive; iris brown; upper

mandible dark brown, lower mandible horn with pinkish base; tarsus and toes olive. Sexes alike. Juvenile has shorter bill, whitish throat with faint brown spots, brown bars on breast feathers, narrower and more pointed rectrices. Race *baeri* has bright olive-brown back, wings not so rufescent (tinged more olive-brown), also duller ochraceous below. **Voice.** Song a brief, soft, accelerating chatter followed by series of harsh, metallic, staccato “cheek” notes, concluding with brief decelerating chatter (thus different in rhythm and more strident tone from congeners, more like *Syndactyla*). Contact call a loud, nasal “chch”, single or doubled.

**Habitat.** Gallery forest and tropical lowland evergreen forest; 100–1200 m.

**Food and Feeding.** Little known. Probably arthropods. Observed usually in pairs, occasionally in mixed-species flocks. Forages along branches and among epiphytes, in understorey and mid-storey; substrate use not reported.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to locally common. A poorly known species. Present in Das Emas Brasília and Serra da Canastra National Parks, in Brazil. In Paraguay, rare in Cerro Corá National Park and present in San Luis National Park.

**Bibliography.** Anon. (2003d), Cavalcanti & Marini (1993), Cory & Hellmayr (1925), Hayes (1995), Hayes & Scharf (1995b), Kratter & Parker (1997), Marini (2001), Novaes (1953), Pinto (1978), Pinto & Camargo (1956), Ridgely & Tudor (1994), Robbins & Zimmer (2003), Robbins *et al.* (1999), Sick (1993, 1997), Silveira (1998), Stotz *et al.* (1996).

Genus *ANABAZENOPS* Lafresnaye, 1842

## 204. Dusky-cheeked Foliage-gleaner

*Anabazenops dorsalis*

**French:** Anabate à grands sourcils **German:** Graubauch-Baumspäher **Spanish:** Ticotico Carioscuro

**Other common names:** Crested/Bamboo Foliage-gleaner

**Taxonomy.** *Automolus dorsalis* P. L. Selater and Salvin, 1880, Sarayacu, Pastaza, Ecuador.

Genus merged by some authors into a broadly defined *Philydor*. This species was until recently placed in genus *Automolus*. Nest structure, voice, habitat, morphometrics, and juvenile and adult plumage patterns all strongly suggest that its sister-species is *A. fuscus*. Monotypic.

**Distribution.** S Colombia (S from W Caquetá) S through extreme W Amazonia to N Bolivia (N La Paz), also locally in S Amazonian Brazil (Acre, Rondônia, N Mato Grosso).

**Descriptive notes.** 19 cm; 34–44 g. Rather thick-billed, plain foliage-gleaner. Has narrow greyish-buff supercilium; rest of face greyish-brown, lores with greyish crescent and paler anterior spot; crown to rump rather uniform dull reddish-brown, faint dark scalloping on crown feathers; uppertail-coverts dull chestnut; wings dull brown, dull tawny bend of wing; tail slightly rounded, rectrices slightly stiffened basally, tips slightly pointed, dark dull chestnut; throat and malar region creamy white; breast and belly grey, with fairly sharp demarcation from throat, flanks olive-brownish, undertail-coverts greyish mixed with dull rufescent; iris brown to dark brown;

upper mandible dusky horn to grey, lower mandible variable, from ivory with dusky tip to olive-grey; tarsus and toes olive to yellowish-olive. Sexes alike. Juvenile has supercilium and underparts suffused tawny-buff, upperparts more rufous. **Voice.** Song 5–24 low-pitched, evenly spaced “chhook” or “chert” notes, c. 4 per second, becoming louder after first few notes, sometimes introduced with chatter; antiphonal duet, one member of pair giving song with chattered introduction, the other a quick series of c. 9 notes during introduction. Contact call a harsh “klek” or “cheff”.

**Habitat.** Humid hilly lowland and foothill forest and second growth, especially near rivers and streams, almost always in or near *Guadua* bamboo thickets or (especially in lowland Ecuador) *Gynerium* cane thickets; mostly 200–1000 m, locally to 1300 m.

**Food and Feeding.** Arthropods. Usually singly or in pairs, occasionally in mixed-species flocks. Forages in upper levels of bamboo or cane-dominated understorey, mostly 4–8 m above ground. Hitches on or up small vertical stems and along horizontal branches and vines, using tail as brace. Gleans and pulls arthropods from dead leaves, debris and branches, especially bases of spine clusters in *Guadua* bamboo. At one site in SE Peru, more than 60% of all observed foraging was directed at *Guadua* bamboo, mostly stems and dead leaves, and almost all foraging outside bamboo directed at dead leaves.

**Breeding.** Nestlings in Aug in S Peru. Presumably monogamous. One nest was a cup 15 cm deep of fine, dried plant material, placed c. 3 m above ground in natural cavity of dead bamboo stem c. 7 cm in diameter. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon. Restriction to bamboo naturally limits its global population size. Occurs in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru.

**Bibliography.** Alonso *et al.* (2001), Angehr & Aucca (1997), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Foster *et al.* (1994), Hilty & Brown (1986), Kratter (1994, 1997a), Kratter & Parker (1997), Parker & Bailey (1991), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Parker, Stotz & Fitzpatrick (1997), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Robinson *et al.* (1990), Stotz *et al.* (1996), Terborgh *et al.* (1984), Whittaker & Oren (1999), Zimmer, J.T. (1935a), Zimmer, K.J. *et al.* (1997).

## 205. White-collared Foliage-gleaner

*Anabazenops fuscus*

**French:** Anabate à col blanc **German:** Halsband-Baumspäher **Spanish:** Ticotico Acollarado  
**Other common names:** Brown Anabazenops

**Taxonomy.** *Sitta fusca* Vieillot, 1816, Rio de Janeiro, Brazil.

Genus merged by some authors into a broadly defined *Philydor*. Nest structure, voice, habitat, morphometrics, and juvenile and adult plumage patterns all strongly suggest that its sister-species is *A. dorsalis*. Monotypic.

**Distribution.** SE Brazil from C Minas Gerais and S Bahia S to E Santa Catarina.

**Descriptive notes.** 20 cm. Rather plain foliage-gleaner with bill slightly wedge-shaped. Has whitish supercilium sharply defined, extending posteriorly to meet white side of neck; rest of face dark brown, some paler flammulations on auriculars, lores grizzled greyish-white, dull buff

brownish lower breast and belly; flanks and undertail-coverts darker, browner; iris dark brown or dark reddish-brown; upper mandible dusky brown with pale horn cutting edges, lower mandible pale horn or pale grey; tarsus and toes olive-grey or brownish-grey or dark olive-brown. Sexes alike. Juvenile has supercilium and underparts suffused tawny-buff. **VOICE.** Song 5-42 low-pitched, evenly spaced "tchook" notes, 4-5 per second, becoming louder after first few notes; antiphonal duet, one member of pair giving sustained chatter. Also distinctive high-pitched,

supraloral streak; crown rich dark brown with faint darker scalloping, partly concealed collar buffy whitish, becoming more prominent and whiter at side of neck; back and rump brown, paler than crown, blending to dull dark rufous uppertail-coverts; wing brown like back, darker brown primary coverts, bright yellowish-buff bend of wing; tail slightly rounded, shafts slightly stiffened basally, slightly pointed (almost rounded) tips, dark rufous; throat and malar area white (made conspicuous in field by feathers being erected); upper breast tawny-tinged greyish-buff, blending to slightly darker, duller tawny-

squeaky "chek, jééurr-jééurr-jééurr-jééurr" (number of downslurred "jééurr" notes variable), and hoarse, syncopated "wrr-jek, wrjejek, wrjejek" also described. Alarm call a piercing "ghéé-eh".

**Habitat.** Montane evergreen forest and secondary forest, usually with extensive bamboo thickets; 350-1200 m.

**Food and Feeding.** Arthropods. Usually in pairs, occasionally to rarely in mixed-species flocks. Forages mainly in mid-storey, less commonly down to understorey, rarely on ground. Climbs up vertical stems. Acrobatically gleans and probes for items on branches (especially nodes of bamboo stems), also green and dead leaves; occasionally hammers holes in bamboo branches. In one study, 87% of all observed foraging attempts were directed at bamboo, mostly stems but also foliage and dead leaves; the rest were at branches, dead leaves, and live leaves of other plants.

**Breeding.** Presumably monogamous. Nest in natural cavity in branch. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout range. Fairly common in Augusto Ruschi Biological Reserve and Itatiaia National Park; uncommon in Serra dos Órgãos National Park; also present in Serra do Mar State Park. Extensive deforestation within its relatively small range has dramatically reduced area of available habitat.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos *et al.* (1997), Cordeiro (2001), Cory & Hellmayr (1925), Goerck (1999a), Gonzaga *et al.* (1995), Kratter & Parker (1997), Parker & Goerck (1997), Pinto (1978), Ridgely & Tudor (1994), Rodrigues *et al.* (1994), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996).

## PLATE 27

## Family FURNARIIDAE (OVENBIRDS) SPECIES ACCOUNTS

### Genus *CICHLOCOLAPTES* Reichenbach, 1853

#### 206. Pale-browed Treehunter

##### *Cichlocolaptes leucophrus*

French: Anabate à sourcils blancs

Spanish: Ticotico Cejipáldo

German: Zimtschwanz-Blattspäher

Other common names: Rusty-rumped Cichlocolaptes

**Taxonomy.** *Anabates leucophrus* Jardine and Selby, 1830, Brazil. Genus has sometimes been merged into a broadly defined *Philydor*. No obvious close relatives; superficial plumage similarities may suggest relationship to *Pseudocolaptes*, *Heliobletus*, *Syndactyla* or *Hyloctistes*, and foraging behaviour perhaps most similar to that of first of those. Species name regularly misspelled as "*leucophrys*". Two subspecies recognized.

##### **Subspecies and Distribution.**

*C. l. leucophrus* (Jardine & Selby, 1830) - SE Brazil (S Bahia S to Rio de Janeiro).

*C. l. holti* (Pinto, 1941) - SE Brazil (São Paulo S to NE Santa Catarina and NE Rio Grande do Sul).

**Descriptive notes.** 18-23 cm. Heavily striped, dagger-billed furnariid reminiscent of some woodcreepers (Dendrocolaptidae) in plumage pattern and shape. Nominative race has buffish-white supercilium extending posteriorly to collar, and anteriorly very narrowly to supraloral region; lores

grizzled blackish and dull buff, postocular band dark brown with faint dark golden shaft streaks; rest of face dull buff, faintly flecked dark brown; crown dark brown with fine, sharply demarcated buff to rusty-buff shaft streaks, vague collar of blackish-brown feathers with broader buff streaks; back rufescent brown with long, blurry buff streaks, rump and uppertail-coverts slightly paler brown with vague buff streaking; wing-coverts brown with inconspicuous buff shaft streaks, remiges rich brown; tail nearly square, shafts stiffened basally, pointed tips, light rufous; throat pale yellowish-buff; breast strongly streaked pale buff

and brown, belly, flanks and undertail-coverts similar but with streaks fading posteriorly; iris very dark; upper mandible dusky grey, lower mandible paler, fleshy brown, greyer towards tip; tarsus and toes greenish-grey or dull yellowish-green to light brownish. Sexes alike. Juvenile has less distinct pattern of streaking on underparts. Race *holti* is substantially smaller, has darker crown, darker back, more conspicuous supercilium, darker rufous tail. **Voice.** Song loud, ringing "reep" notes, variable in number, sometimes interspersed with fast chattering notes; gives antiphonal duet. Call a loud "krip, shrip".

**Habitat.** Tropical lowland and montane evergreen forest; from near sea-level to 1400 m.

**Food and Feeding.** Arthropods. Forages, perhaps usually in mixed-species flocks, from understorey to subcanopy. Moves along larger limbs and branches, often disappears completely into clumps of

epiphytes. Probes and gleans for items, mainly from bromeliads and other epiphytic plants and from dead leaves.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Rare to locally fairly common. Fairly common in Sooretama and Augusto Ruschi Biological Reserves, Serra do Mar State Park and Serra dos Órgãos National Park; uncommon in Itatiaia National Park. Extensive deforestation within its relatively small range has dramatically reduced the area of its habitat.

**Bibliography.** Aleixo & Galetti (1997), dos Anjos *et al.* (1997), Bencke (2001), Bencke & Kindel (1999), Cordeiro (2001), Cory & Hellmayr (1925), Goerck (1999a), Kratter & Parker (1997), Naka *et al.* (2001), Pacheco & Whitney (1997), Parker & Goerck (1997), Pinto (1941, 1978), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), da Silva & Stotz (1992), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Whitney (2003c).

## Genus *THRIPADECTES* P. L. Sclater, 1862

### 207. Uniform Treehunter

#### *Thripadectes ignobilis*

**French:** Anabate uniforme **German:** Rotbrauner Baumspäher **Spanish:** Trepamusgos Uniforme  
**Other common names:** Chestnut-rumped Treehunter

**Taxonomy.** *Automolus ignobilis* P. L. Sclater and Salvin, 1879, Frontino, Antioquia, Colombia. No obvious sister-species within genus. Small size, relatively short bill and more arboreal foraging have suggested to some authors that this species should be treated in a monotypic genus. Monotypic.  
**Distribution.** Pacific slope of W Andes in Colombia (S from Chocó) and NW Ecuador (S to El Oro).

**Descriptive notes.** 19-20 cm; 48-51 g. The smallest, shortest-billed and darkest of genus. Has narrow, indistinct supercilium and broad but vague eyering dull tawny-rufous, lores blackish-brown grizzled with pale buff, auriculars blackish with narrow ochraceous-buff shaft streaks; side of neck and malar area dark brown with blurry dark ochraceous to rufescent brown streaks and spotting; crown dark brown, vague paler brown spotting on forehead; back and rump slightly paler and redder than crown, uppertail-coverts still slightly paler and redder; wings mostly rich dark reddish-brown; tail slightly graduated,

shafts slightly stiffened basally, pointed tips often with distal 1-2 cm without barbs (possibly only through wear), rich dark reddish-brown; throat dull dark buff with blurry broad dark brownish streaks; breast rich dark brown with narrow buff shaft streaks, belly similar but streaks vanish posteriorly, flanks dark reddish-brown, undertail-coverts slightly paler; iris dark brown; upper mandible dark brownish, lower mandible blackish with reddish-horn base to dusky yellow with dark tip; tarsus and toes greenish-brown. Sexes alike. Juvenile undescribed. VOICE. Song a fast series of 6-8 "kyip" notes.

**Habitat.** Montane evergreen forest, locally to tropical lowland evergreen forest; also tall second growth. Mostly 700-1700 m, locally down to 200 m and up to 2500 m.

**Food and Feeding.** Arthropods; reported items include a worm or insect larva 5 cm long. Usually singly, often in mixed-species flocks (evidently the only member of genus to participate so regularly). Forages in dense undergrowth, occasionally to mid-storey. Moves along low branches; gleans items from dead leaves, debris and branches.

**Breeding.** Active nest found in Jun; nestlings in Sept. Presumably monogamous. Nest in tunnel excavated in dirt bank; chicks fed by both adults. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon to locally fairly common. Occurs in Rio Nambi Natural Reserve and La Planada Nature Reserve, in Colombia.

**Bibliography.** Chapman (1926), Cory & Hellmayr (1925), Hilty (1997), Hilty & Brown (1986), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Salaman (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Strew (2000a, 2001).

### 208. Streak-breasted Treehunter

#### *Thripadectes rufobrunneus*

**French:** Anabate des ravins **Spanish:** Trepamusgos Pechirrayado  
**German:** Ockerkehl-Baumspäher  
**Other common names:** Streaked Treehunter, Streak-breasted Leaf-gleaner

**Taxonomy.** *Philydor rufobrunneus* Lawrence, 1865, San José, Costa Rica.

Considered by some authors to be sister-species of *T. virgaticeps*, despite distance between the two in current linear sequences. Monotypic.

**Distribution.** Mountains of Costa Rica and W Panama (E to Veraguas).

**Descriptive notes.** 20-22 cm; 48-54 g. Bulky, dark furnariid with shape somewhat like that of a thrush (Turdidae). Face is mostly dark brown, with dull rufescent flammulations on auriculars; malar area dark ochraceous with dark flecking; crown blackish with long olive streaks, vague collar olive with feathers margined blackish, becoming dull rufous at side of neck; back and rump rich dark brown, blending to dark reddish-brown uppertail-coverts; wings rich dark brown, primary coverts slightly darker; tail graduated, shafts stiffened basally, pointed tips with distal 1-2 cm

lacking barbs, rich chestnut-brown; throat dull ochraceous, darker along lower border, with dull brownish streaks; breast and belly brown with narrow dull ochraceous streaks that diminish posteriorly, vanishing on lower belly, flanks darker, richer brown, undertail-coverts dark reddish-brown with vague chestnut shaft streaks; iris dark brown; bill black, sometimes base of lower mandible dull greenish-grey or greyish-horn; tarsus and toes dark brownish-grey to greenish-grey. Sexes alike. Juvenile has streaking on upper breast paler and less well defined, blackish edgings on crown feathers less distinct. VOICE. Song a series of rolling,

burry "chi-wówr" notes; also described as a series of scratchy "ek" notes accelerating into rattle. Call a harsh, grating "zeck" or "tseck" or "cheyt, cheyt"; doubled "rek-rek" also given; also prolonged grating scold, or repeated "ti-chr", possibly another version of song.

**Habitat.** Montane evergreen forest, especially in epiphyte-laden steep ravines above and along streams; also tall second growth. At 700-3000 m.

**Food and Feeding.** Arthropods, small vertebrates; recorded dietary items are Coleoptera, Orthoptera including katydids (Tettigoniidae), cockroaches (Blattodea), Lepidoptera larvae, spiders, also frogs, lizards, salamanders (*Salamandra*). Usually singly, rarely in pairs, rarely in mixed-species flocks. Forages in dense undergrowth; hops and clammers along branches, sometimes hanging down. Gleans invertebrates and small vertebrates from dead leaves, debris, moss and epiphytes (including bromeliads); tears apart large dead-leaf clusters and tank bromeliads.

**Breeding.** Season Feb-Aug; eggs in Feb-Mar and Aug, and nestlings in May. Monogamous. Nest a shallow woven pad of leaf stems or rootlets, placed in expanded chamber 15 cm in diameter at end of tunnel 45-70 cm long, curving and slanting upwards, presumably excavated by the birds themselves, in dirt bank. Clutch 2 eggs; incubation by male, possibly by both sexes; both feed nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Uncommon to locally fairly common. Present in fragmented forests.

**Bibliography.** Anon. (1998a), Blake & Loiselle (2000), Cory & Hellmayr (1925), Hartman (1957), Kiff *et al.* (1989), Marin & Carrión (1994), Remsen (2003a), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Skutch (1969c), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Worth (1939), Zyskowski & Prum (1999).

### 209. Black-billed Treehunter

#### *Thripadectes melanorhynchus*

**French:** Anabate à bec noir **Spanish:** Trepamusgos Piquinegro  
**German:** Schuppenkehl-Baumspäher

**Taxonomy.** *Anabates melanorhynchus* Tschudi, 1844, forest region of Peru between 10° S and 12° S. Two subspecies recognized.

**Subspecies and Distribution.**

*T. m. striaticeps* (P. L. Sclater & Salvin, 1875) - E Andes of Colombia (S from Boyacá and W Casanare).

*T. m. melanorhynchus* (Tschudi, 1844) - E Andes in Ecuador (S from Sucumbios) and Peru (S to Puno).

**Descriptive notes.** 20-21 cm; 39-46 g. Bulky, dark furnariid shaped somewhat like a thrush (Turdidae); the only *Thripadectes* with scaly throat and virtually unstreaked underparts. Has blackish-brown face with sharply defined buff shaft streaks, some coalescing into interrupted supercilium, lores grizzled blackish-brown and buff; crown blackish-brown with narrow, striking buff shaft streaks; back dark brown with similar streaks, rump dull dark brown, blending to reddish-brown uppertail-coverts; wings mostly rich brown; tail slightly graduated, shafts slightly stiffened basally, slightly pointed at tips, dark chestnut-brown; throat ochraceous with dark brownish margins increasingly broad posteriorly, producing scaly look; breast rufescent brown with faint pale shaft streaks, belly slightly duller without streaks (except uppermost margin), flanks and undertail-coverts darker rufescent-brown; iris brown to dark brown; bill black; tarsus and toes blackish-grey to brown. Distinguished from very similar *T. holostictus* by virtually unstreaked underparts. Sexes alike. Juvenile has less distinct throat markings and back streaks. Race *striaticeps* is paler and less sooty on crown, back and auriculars than nominate, wings more rufescent, back streaks broader. VOICE. Song an accelerating, then decelerating, slightly descending series of c. 10-13 sharp "kyip" notes with "laughing" quality.

**Habitat.** Montane evergreen forest; also second growth, and stunted forest on ridges. At 1000-1700 m.

**Food and Feeding.** Arthropods, possibly also small vertebrates; recorded items include grasshoppers (Acrididae). Usually singly, rarely in mixed-species flock, in dense undergrowth. Food items obtained by gleaning, but substrate use not well known.

**Breeding.** Eggs in Oct in Ecuador. Presumably monogamous. Nest a pad of leaf stems placed in enlarged chamber at end of tunnel 1 m long, sloping slightly upwards, in dirt bank. One clutch contained 3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common. Race *striaticeps* known from only one locality, but almost certainly more widespread. Occurs in a number of protected areas, e.g. Podocarpus National Park, in Ecuador.

**Bibliography.** Bohórquez (2002), Bond (1945), Cory & Hellmayr (1925), Ejdlsá & Krabbe (1990), Graves (1985), Hilty & Brown (1986), Kiff *et al.* (1989), Marin & Carrión (1994), Parker *et al.* (1982), Remsen (2003a), Renjifo *et*

al. (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Zimmer (1936c).

## 210. Striped Treehunter

### *Thripadectes holostictus*

**French:** Anabate strié **German:** Strichelbaumpäher **Spanish:** Trepamusgos Listado

**Taxonomy.** *Automolus holostictus* P. L. Slater and Salvin, 1876, Medellín, Antioquia, Colombia. Race *striatidorsus* (Berlepsch & Taczanowski, 1884) - W Andes of W Colombia (S from Cauca) and W Ecuador (S to Chimborazo). *T. h. holostictus* (P. L. Slater & Salvin, 1876) - Andes of W Venezuela (SW Táchira), Colombia (C range, and E range from Norte de Santander S to Cundinamarca), E Ecuador and N Peru (La Libertad).

#### Subspecies and Distribution.

*T. h. striatidorsus* (Berlepsch & Taczanowski, 1884) - W Andes of W Colombia (S from Cauca) and W Ecuador (S to Chimborazo).

*T. h. holostictus* (P. L. Slater & Salvin, 1876) - Andes of W Venezuela (SW Táchira), Colombia (C range, and E range from Norte de Santander S to Cundinamarca), E Ecuador and N Peru (La Libertad).

*T. h. moderatus* J. T. Zimmer, 1935 - Andes from C Peru (Huánuco) S to C Bolivia (Cochabamba).

**Descriptive notes.** 20-21 cm; 38-49 g. Bulky, streaked furnariid resembling a thrush (Turdidae) in shape; remarkably similar to *Syndactyla subalaris*. Nominative race has blackish-brown face with buff shaft streaks, some coalescing into interrupted supercilium, lores grizzled blackish-brown and buff; crown blackish-brown with strong buff shaft streaks; back dark brown with broad buff streaks, rump dull dark brown, blending to reddish-brown uppertail-coverts; wings mostly rich brown; tail slightly graduated, shafts slightly stiffened basally, slightly pointed at tips, dark chestnut-brown; throat dull tawny-buff with dark brownish margins increasing in width posteriorly, producing short broad streaks, this pattern extending to upper breast; rest of breast medium brown with sharply defined pale buff shaft streaks, belly similar but slightly duller, streaks vanishing on lower belly, flanks darker, more rufescent, undertail-coverts darker than belly, tinged reddish-brown; iris brown to dark brown; bill black, sometimes base of lower mandible greenish-grey or greyish-horn; tarsus and toes olive-brown to greenish-grey. Distinguished from very similar *T. melanorhynchus* by heavily streaked underparts. Sexes alike. Juvenile has streaks on upperparts narrower, belly unstreaked but mottled. Race *striatidorsus* is very like nominate, but possibly with wings more reddish, flanks more rufescent, edges of throat feathers browner, less blackish; *moderatus* differs in having underparts more rufescent, less olive, with streaks narrower and tinged pale rufescent, and not extending so far posteriorly, also lateral margins of throat feathers more olive, less sooty. Voice. Song a fast series of nasal chattering notes, slightly descending and decelerating; call described as sharp, fast "kwi-di-dik".

**Habitat.** Montane evergreen forest, especially in or near *Chusquea* bamboo thickets, locally ranging into second growth. Mostly 1500-2500 m; locally down to 900 m on W slope of W Andes in Colombia, and up to 3000 m in Ecuador.

**Food and Feeding.** Invertebrates, possibly also small vertebrates. Usually forages singly, very occasionally in mixed-species flocks. Probes and gleans dead leaves and other debris trapped in dense undergrowth, usually within 1 m of ground; possibly a dead-leaf specialist.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common throughout range. Occurs in a number of protected areas, e.g. Machu Picchu Historical Sanctuary, in Peru.

**Bibliography.** Bond (1945), Chapman (1926), Cory & Hellmayr (1925), Cuervo *et al.* (2003), Fjeldså & Krabbe (1990), Graves (1985), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee (1945), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Peters & Griswold (1943), Remsen (2003a), Remsen & Parker (1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman (1994), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Stotz *et al.* (1996), Walker (2001), Zimmer (1935b, 1936c).

## 211. Streak-capped Treehunter

### *Thripadectes virgaticeps*

**French:** Anabate à tête striée **Spanish:** Trepamusgos Cabecirrayado  
**German:** Ockerkinn-Baumpäher

**Taxonomy.** *Thripadectes virgaticeps* Lawrence, 1874, "Quito", Ecuador.

Considered by some authors to be sister-species of *T. rufobrunneus*, despite distance between the two in current linear sequences. Population in E Andes of S Colombia (in E Nariño) previously considered to belong to race *magdalenae*, but probably referable to *sumaco*; all races in Colombia and Ecuador in need of re-evaluation. Race *scelateri* possibly intergrades with nominate in SW Colombia. Six subspecies recognized.

#### Subspecies and Distribution.

*T. v. klagesi* (Hellmayr & Seifern, 1912) - N Venezuela (coastal range from Carabobo E to Distrito Federal).

*T. v. tachirensis* Phelps, Sr. & Phelps, Jr., 1958 - Andes of W Venezuela (SW Lara, SW Táchira).

*T. v. magdalenae* Meyer de Schauensee, 1945 - W Colombia (W Andes in S Chocó, and E slope of C range in Antioquia and SW Huila).

*T. v. scelateri* Berlepsch, 1907 - W Andes of SW Colombia (Valle S to Nariño).

*T. v. virgaticeps* Lawrence, 1874 - W Andes of Ecuador (Carchi S to Pichincha).

*T. v. sumaco* Chapman, 1925 - E Andes in S Colombia (Cauquetá, E Nariño) and N Ecuador (W Napo).

**Descriptive notes.** 22-23 cm; 61-65 g. Rather large *Thripadectes* with relatively little streaking. Nominative race has blackish brown face with pale buff shaft streaks, lores grizzled blackish-brown and greyish-buff; crown blackish-brown, dull buff shaft spotting on forehead becoming

streaking on crown; vague collar dark brown with faint buff shaft streaks; back rich dark brown, hint of pale shaft streaks on upper back, blending to slightly redder rump; uppertail-coverts reddish-brown; wings mainly rich dark rufescent brown; tail slightly graduated, shafts slightly stiffened basally, nearly rounded tips, dark chestnut-brown; throat and malar area tawny-buff with dark brownish streaking intensifying posteriorly, pattern continues into upper breast, where streaking "reverses" and becomes restricted to narrow buff shaft streaks; rest of breast and belly rich rufescent brown, flanks darker, undertail-coverts dark reddish-brown; iris dark brown; bill black; tarsus and toes greenish-grey to blackish (source of variation unknown). Sexes alike. Juvenile almost lacks throat markings. Race *sumaco* has crown streaks evidently extending to nape, is less rufous on wing-coverts, outer webs of primaries and underparts, especially undertail-coverts, bill much shorter; *scelateri* is like nominate, but has duller, more olive (less rufous) back, paler and less extensive rufous on rump; *magdalenae* is most similar to previous, but has less conspicuous throat markings, slightly more olivaceous upperparts, brighter, more golden underparts, shorter bill; *klagesi* has but crown greyer than nominate and with more conspicuous pale streaks, back slightly paler, rufous of rump and tail lighter, hint of pale supercilium, throat more heavily marked blackish, substantially shorter bill; *tachirensis* is similar to last but darker, more ochraceous, below, dusky wash on breast, darker, more brownish (less yellowish) back, darker and less reddish rump and uppertail-coverts. Voice. Song described as series of emphatic notes, "chup, cheyp-cheyp-cheyp-cheyp...". Call a fast, sharp "ch-di-dit", "chi-dik" or "ju-dut", repeated at intervals of several seconds; alarm a nasal "jwick".

**Habitat.** Montane evergreen forest, locally ranging into second growth. Mostly 1300-2100 m, occasionally to 2500 m; down to 900 m on Pacific slope of W Andes in SW Colombia.

**Food and Feeding.** Invertebrates; also, an *Anolis* lizard recorded, and other small vertebrates may also be taken. Forages singly or in pairs, rarely to occasionally in mixed-species flocks, mainly in understorey. Gleans and probes mossy branches and debris in dense undergrowth.

**Breeding.** Active nests in Apr-Aug in W Colombia; nestlings in Jun in Ecuador. Presumably monogamous. Nest a shallow platform of rootlets placed in tunnel c. 0.6 m long excavated in dirt bank, nest-chamber c. 15 cm long and 10 cm high. One clutch documented, of 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout range. Occurs in Henri Pittier National Park, in Venezuela, and La Planada Nature Reserve, in Colombia.

**Bibliography.** Anon. (2003g), Bohórquez (2002), Chapman (1926), Collins *et al.* (1991), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Hilty (2003a), Hilty & Brown (1983, 1986), Marin & Carrión (1994), Meyer de Schauensee (1945), Miller (1963), Pearman (1994c), Phelps & Phelps (1958), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman (1994), Stotz *et al.* (1996), Willis & Schuchmann (1993).

## 212. Flammulated Treehunter

### *Thripadectes flammulatus*

**French:** Anabate flammé **German:** Streifenbaumpäher **Spanish:** Trepamusgos Flamulado

**Taxonomy.** *Anabates flammulatus* Eyton, 1849, New Grenada = "Bogotá", Colombia.

Forms a superspecies with *T. scrutator*, and suggested by some authors as being possibly conspecific. Two subspecies recognized.

#### Subspecies and Distribution.

*T. f. bricenoi* Berlepsch, 1907 - Andes of W Venezuela (Mérida).

*T. f. flammulatus* (Eyton, 1849) - Santa Marta Mts (NE Colombia) and Andes of SW Venezuela (Táchira), Colombia (W Andes from Antioquia S to Cauca, C range, E range from Norte de Santander S to Cundinamarca), Ecuador (but on W slope S only locally to Azuay) and extreme N Peru (Piura, Cajamarca).

**Descriptive notes.** 24-25 cm; 50-62 g. The largest and most strikingly patterned *Thripadectes*. Nominative race has lores speckled blackish and golden buff, face and crown blackish with sharply defined tawny-buff streaks, these more golden on crown; back similar but browner, with blackish restricted to margins of shaft streaks, blending to rich medium brown rump; uppertail-coverts dark reddish-brown; wing-coverts like back but more rufescent, streaks narrower, remiges dark rufescent brown; tail graduated, shafts stiffened basally, slightly pointed tips, dull chestnut-brown; throat, breast and upper belly streaked

golden buff and blackish, streaks fading into rich brown lower belly and flanks; undertail-coverts streaked dark rufous-brown and blackish; iris brown to dark brown; bill black; tarsus and toes blackish to grey-brown. Sexes alike. Juvenile is less distinctly streaked. Race *bricenoi* is generally paler than nominate, with throat almost uniform buff, underparts margined with olive-brown, not black, undertail-coverts ochraceous, not rufous, shaft streaks on upperwing-coverts broader and more conspicuously edged blackish. Voice. Song described as a series of grating notes that start as a stutter, then accelerates and becomes louder, c. 2 seconds long, repeated at intervals of 3-5 seconds; contact call an emphatic sharp "check", similar to notes of song.

**Habitat.** Montane evergreen forest, especially in or near *Chusquea* bamboo thickets; mostly 2200-3500 m, locally down to 800 m on Pacific slope of W Andes in Colombia.

**Food and Feeding.** Arthropods, presumably also small vertebrates. Forages usually singly, rarely to occasionally in mixed-species flocks, in dense undergrowth. Food items obtained by gleaning, presumably from moss, branches and debris, but substrate use not well known.

**Breeding.** Presumably monogamous. Nest in tunnel excavated in dirt bank. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon in general. Not well known. Occurs in Podocarpus National Park and Pasochoa Forest Reserve, in Ecuador.

**Bibliography.** Cory & Hellmayr (1925), Cuervo & Delgado (2001), Cuervo *et al.* (2003), Fjeldså & Krabbe (1990), Hilty (1985, 2003a), Hilty & Brown (1986), Olivares (1969), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Phelps & Phelps (1958), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994),

Rodner *et al.* (2000), Salaman (1994), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Stotz *et al.* (1996).

## 213. Rufous-backed Treehunter

### *Thripadectes scrutator*

**French:** Anabate inca **German:** Braunrücken-Baumspäher **Spanish:** Trepamusgos Peruano  
**Other common names:** Peruvian/Buf-throated/Taczanowski's Treehunter

**Taxonomy.** *Thripadectes scrutator* Taczanowski, 1874, Maraynioc, Junin, Peru.

Forms a superspecies with *T. flammulatus*, and suggested by some authors as being possibly conspecific. Some specimens from S Peru (Cuzco) and Bolivia (Cochabamba) more reddish rufescent than those farther N, perhaps representing undescribed race. Monotypic.

**Distribution.** Andes, from N Peru (Amazonas) S to NC Bolivia (Cochabamba).

**Descriptive notes.** 23-24 cm; 56-61g. Rather large *Thripadectes*, looking like a washed-out, less streaked version of *T. flammulatus*. Has blackish face with sharply defined tawny-buff streaks, lores speckled blackish and golden buff; crown, side of neck and upper back blackish with broad dull tawny shaft streaks, these becoming brighter posteriorly; rest of back rich brown with faint pale rufous shaft streaks, blending to rusty-brown rump; uppertail-coverts reddish-chestnut; wing-coverts reddish-brown, remiges paler, chestnut-rufous; tail graduated, shafts stiffened basally, slightly pointed tips, dull chestnut-brown; throat dull buff with blackish streaks, blending to upper breast with blacker and bright tawny-buff streaks; rest of breast, belly and flanks medium brown with golden-buff shaft streaks, these fading posteriorly, undertail-coverts ochraceous rufous with paler

not well known.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon throughout range. Poorly known species, and difficult to locate. Whether apparent gap in its range is real or is result of a lack of observations is unknown. Occurs in Machu Picchu Historical Sanctuary, in Peru, and Ulla Ulla Reserve, in Bolivia.

**Bibliography.** Cory & Hellmayr (1925), Fjeldsá & Krabbe (1990), Graves (1985), Parker *et al.* (1982), Remsen (2003a), Remsen & Ridgely (1980), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001).

streaks; iris brown to dark brown; bill black; tarsus and toes grey to brown. Sexes alike. Juvenile undescribed. **VOICE.** Inadequately documented; song (and possibly calls) similar to that of *T. flammulatus*.

**Habitat.** Montane evergreen forest and elfin forest, often with *Chusquea* bamboo; 2450-3200 m.

**Food and Feeding.** Invertebrates, presumably also some small vertebrates; a spiral snail recorded as taken. Forages usually singly, rarely in mixed-species flocks, in dense undergrowth. Items obtained by gleaning, presumably from moss, branches and debris, but substrate use

*ssp ochrolaemus*

214
